# Contents

**Preface** **ii**

**1 Starting LispWorks 1**

The usual way to start LispWorks 1  
Passing arguments to LispWorks 1  
Starting the LispWorks Graphical IDE 3  
Using LispWorks with SLIME 3  
Quitting LispWorks 4

**2 The Listener 5**

First use of the listener 5  
Standard listener commands 6  
The listener prompt 8

**3 The Debugger 9**

Entering the REPL debugger 10  
Simple use of the REPL debugger 11  
The stack in the debugger 12  
REPL debugger commands 13  
Debugger troubleshooting 23  
Debugger control variables 23  
Remote debugging 25

**4 The REPL Inspector 37**

Describe 37  
    Inspect 38  
    Inspection modes 40

## **5 The Trace Facility 47**

    Simple tracing 47  
    Tracing options 49  
    Example 56  
    Tracing methods 57  
    Tracing subfunctions 58  
    Trace variables 59  
    Troubleshooting tracing 60

## **6 The Advice Facility 63**

    Defining advice 64  
    Combining the advice 65  
    Removing advice 66  
    Advice for macros and methods 67  
    Advising subfunctions 69  
    Examples 70  
    Advice functions and macros 73

## **7 Dspecs: Tools for Handling Definitions 75**

    Dspecs 75  
    Forms of dspecs 76  
    Dspec namespaces 77  
    Types of relations between definitions 81  
    Details of built-in dspec classes and aliases 82  
    Subfunction dspecs 85  
    Tracking definitions 87  
    Finding locations 89  
    Users of location information 89

## **8 Action Lists 95**

    Defining action lists and actions 96  
    Exception handling variables 96  
    Other variables 97

Diagnostic utilities	97
Examples	97
Standard Action Lists	99

## **9 The Compiler 101**

Compiling a function	102
Compiling a source file	103
Compiling a form	103
How the compiler works	103
Compiler control	104
Declare, proclaim, and declaim	109
Optimizing your code	110
Compiler parameters affecting LispWorks	116

## **10 Code Coverage 119**

Using Code Coverage	119
Manipulating code coverage data	121
Preventing code generation for some forms	122
Code coverage and multithreading	123
Counting overflow	123
Memory usage and code speed	123
Understanding the code coverage output	124
Coloring code that has changed	127

## **11 Memory Management 129**

Introduction	129
Guidance for control of the memory management system	130
Memory Management in 32-bit LispWorks	135
Memory Management in 64-bit LispWorks	146
The Mobile GC	151
Common Memory Management Features	163

## **12 The Profiler 167**

What the profiler does	167
Setting up the profiler	168
Running the profiler	169
Profiler output	170

Profiling pitfalls	172
Profiling and garbage collection	173
Profiler tree file format	174

## **13 Customization of LispWorks 177**

Introduction	177
Configuration and initialization files	178
Saving a LispWorks image	179
Saved sessions	182
Load and open your files on startup	184
Customizing the editor	185
Finding source code	186
Controlling redefinition warnings	187
Specifying the initial working directory	187
Using ! for :redo	188
Customizing LispWorks for use with your own code	188
Structure printing	189
Configuring the printer	189

## **14 LispWorks as a dynamic library 191**

Introduction	191
Creating a dynamic library	192
Initialization of the dynamic library	193
Relocation	194
Multiprocessing in a dynamic library	195
Unloading a dynamic library	195

## **15 Java interface 197**

Types and conversion between Lisp and Java	198
Calling from Lisp to Java	200
Calling from Java to Lisp	206
Working with Java arrays	210
Initialization of the Java interface	213
Utilities and administration	213
Loading a LispWorks dynamic library into Java	217
CLOS partial integration	218
Java interface performance issues	220

**16 Android interface 223**

- Delivering for Android 224
- Directories on Android 227
- The Othello demo for Android 227

**17 iOS interface 241**

- Delivering for iOS 241
- Initializing LispWorks 243
- Using Objective-C from Lisp 243
- Limitations of the iOS Runtime 243
- The Othello demo for iOS 244
- The Mobile GC 247

**18 The Metaobject Protocol 249**

- Metaobject features incompatible with AMOP 249
- Metaobject features additional to AMOP 252
- Common problems when using the MOP 252
- Implementation of virtual slots 253

**19 Multiprocessing 261**

- Introduction to processes 261
- Processes basics 262
- Atomicity and thread-safety of the LispWorks implementation 265
- Locks 277
- Modifying a hash table with multiprocessing 279
- Process Waiting and communication between processes 280
- Synchronization between threads 285
- Killing a process, interrupts and blocking interrupts 288
- Timers 293
- Process properties 294
- Other processes functions 294
- Native threads and foreign code 296
- Low level operations 299

**20 Common Defsystem and ASDF 305**

- Introduction 305
- Defining a system 306

Using ASDF	311
<b>21 The Parser Generator</b>	<b>313</b>
Introduction	313
Grammar rules	313
Functions defined by defparser	315
Error handling	316
Interface to lexical analyzer	317
Example	317
<b>22 Dynamic Data Exchange</b>	<b>321</b>
Introduction	321
Client interface	323
Server interface	327
<b>23 Common SQL</b>	<b>331</b>
Introduction	331
Initialization	334
Functional interface	346
Object oriented interface	354
Symbolic SQL syntax	358
Working with date fields	370
SQL I/O recording	372
Error handling in Common SQL	372
Using MySQL	373
Using Oracle	379
Oracle LOB interface	380
Using ODBC	390
Using SQLite	392
<b>24 User Defined Streams</b>	<b>399</b>
Introduction	399
An illustrative example of user defined streams	399
<b>25 TCP and UDP socket communication and SSL</b>	<b>407</b>
Running a server that accepts connections	407
Connecting to a server	408

Specifying the target for connecting and binding a socket	408
Information about IP addresses	409
Waiting on a socket stream	410
Special considerations	410
Asynchronous I/O	411
Using SSL	418
Socket streams with Java sockets and SSL on Android	432

## **26 Internationalization: characters, strings and encodings 435**

Introduction	435
Unicode support	435
Character and String types	436
String accessors	440
String Construction	441
External Formats	443
16-bit External formats guide	445
External Formats and File Streams	447
External Formats and the Foreign Language Interface	450
Unicode character and string functions	451

## **27 LispWorks' Operating Environment 453**

The Operating System	453
Site Name	453
The Lisp Image	454
The Command Line	454
Address Space and Image Size	458
Startup relocation	459
Calling external programs	462
Snapshot debugging of startup errors	463
System message log	463
Exit status	463
Creating a new executable with code preloaded	464
User Preferences	464
File system interface	465
Special locations in the file system	466
Accessing the Windows registry	468

Pathname comparison on Mac OS X	469
<b>28 Miscellaneous Utilities</b>	<b>471</b>
Object addresses and memory	471
Optimized integer arithmetic and integer vector access	472
Transferring large amounts of data	476
Rings	476
Conditional throw and checking for catch in the dynamic environment	476
Checking for a dynamic binding	476
<b>29 64-bit LispWorks</b>	<b>477</b>
Introduction	477
Heap size	478
Architectural constants	479
Speed	479
Memory Management and cl:room	479
Greater allocation expected in 64-bit LispWorks	479
Float types	480
External libraries	480
<b>30 Self-contained examples</b>	<b>481</b>
COMM examples	481
Streams examples	482
DDE examples	482
Parser generator examples	482
Examples for save-image in a Mac OS X application bundle	482
Miscellaneous examples	483
<b>31 The CLOS Package</b>	<b>485</b>
break-new-instances-on-access	485
break-on-access	486
class-extra-initargs	487
compute-class-potential-initargs	488
compute-discriminating-function	490
compute-effective-method-function-from-classes	490
copy-standard-object	493
funcallable-standard-object	494

process-a-class-option 495  
process-a-slot-option 497  
replace-standard-object 499  
set-clos-initarg-checking 501  
set-make-instance-argument-checking 502  
slot-boundp-using-class 502  
slot-makunbound-using-class 503  
slot-value-using-class 504  
trace-new-instances-on-access 505  
trace-on-access 506  
unbreak-new-instances-on-access 509  
unbreak-on-access 509  
untrace-new-instances-on-access 510  
untrace-on-access 510

## 32 The COMM Package 513

accept-tcp-connections-creating-async-io-states 513  
accepting-handle 517  
accepting-handle-collection 518  
accepting-handle-name 519  
accepting-handle-local-port 520  
accepting-handle-socket 520  
accepting-handle-user-info 521  
apply-in-wait-state-collection-process 522  
async-io-state 523  
async-io-state-abort 523  
async-io-state-abort-and-close 525  
async-io-state-address 526  
async-io-state-attach-ssl 526

# Preface

## About this manual

This manual contains a user guide section (previously published separately as the *LispWorks User Guide*) and a reference section (previously the *LispWorks Reference Manual*).

## User Guide section

The user guide section of this manual describes the main language-level features and tools available in LispWorks, and how to use them.

These chapters describe the central programming tools and features in LispWorks:

- Chapter 1, “Starting LispWorks” describes how to start LispWorks and supply command line arguments.
- Chapter 2, “The Listener” describes the read-eval-print loop (REPL) listener.
- Chapter 3, “The Debugger” describes the REPL debugger.
- Chapter 4, “The REPL Inspector” describes the REPL inspector.
- Chapter 5, “The Trace Facility” describes the tracer.
- Chapter 6, “The Advice Facility”.

- Chapter 7, “Dspecs: Tools for Handling Definitions” describes the naming system for Lisp definitions, and in particular how to locate these.
- Chapter 8, “Action Lists” describes how you can run code at various hook points.
- Chapter 9, “The Compiler” describes the compiler optimization qualities and some ways to optimize your code.
- Chapter 10, “Code Coverage” shows you how to determine and visualize which parts of your program have actually run.
- Chapter 11, “Memory Management” covers the behavior (and for wizard level users, configuration) of the garbage collector.
- Chapter 12, “The Profiler” describes a tool for identifying bottlenecks impeding performance of your program.

The next chapter, Chapter 13, “Customization of LispWorks”, explains how to perform some commonly required customizations, such as controlling start-up appearance of LispWorks.

The remaining user guide chapters describe features of specialist interest:

- Chapter 14, “LispWorks as a dynamic library” describes how LispWorks operates as a DLL, .dylib or .so.
- Chapter 15, “Java interface” describes the LispWorks Java interface.
- Chapter 16, “Android interface” describes the LispWorks Android interface, which allows you to include a LispWorks runtime in an Android app.
- Chapter 17, “iOS interface” describes the LispWorks iOS interface, which allows you to include a LispWorks runtime in an iOS app.
- Chapter 18, “The Metaobject Protocol” describes how the LispWorks MOP implementation differs from AMOP.
- Chapter 19, “Multiprocessing”, including locks.
- Chapter 20, “Common Defsystem and ASDF” describes how to use `defsystem` to combine a series of source files into a manageable project.
- Chapter 21, “The Parser Generator”.

- Chapter 22, “Dynamic Data Exchange” describes how to implement DDE functionality in your Microsoft Windows applications.
- Chapter 23, “Common SQL” explains how to use LispWorks to communicate with databases using SQL.
- Chapter 24, “User Defined Streams” provides an illustrative example showing how to define and implement your own streams.
- Chapter 25, “TCP and UDP socket communication and SSL” describes the use of socket streams, including the Secure Sockets Layer (SSL).
- Chapter 26, “Internationalization: characters, strings and encodings” provides an overview of using international characters.
- Chapter 27, “LispWorks’ Operating Environment” explains how to find information about the Operating System and how LispWorks was started.
- Chapter 28, “Miscellaneous Utilities” describes miscellaneous functionality which does not belong in other chapters.
- Chapter 29, “64-bit LispWorks” outlines differences between 64-bit LispWorks and 32-bit LispWorks.
- Chapter 30, “Self-contained examples” enumerates the example files which are relevant to the content of this manual and are available in the LispWorks library.

Please note that documentation for Graphics Ports is in the *CAPI User Guide and Reference Manual*.

## Reference section

Most of the reference section is organized by package: each chapter contains reference material for the exported symbols in a given package. The chapters are organized alphabetically by package name.

Generally one chapter covers each package, but the `WIN32` package symbols are split into four chapters, and the last chapter contains reference material for C functions. Within each chapter, the symbols are organized alphabetically (ignoring non-alphanumeric characters that are common in Lisp symbols, such as `*`). The chapters are:

- Chapter 31, “The CLOS Package”, describes the LispWorks extensions to CLOS, the Common Lisp Object System.
- Chapter 32, “The COMM Package”, describes the functions providing the TCP/IP interface.
- Chapter 33, “The COMMON-LISP Package”, describes the LispWorks extensions to symbols in the `COMMON-LISP` package. You should refer to the Common Lisp HyperSpec, supplied in HTML format with LispWorks, for full documentation about standard Common Lisp symbols.
- Chapter 34, “The COMPILER Package”, describes symbols available in the `COMPILER` package.
- Chapter 35, “The DBG Package”, describes symbols available in the `DBG` package, used to configure the debugging information produced by LispWorks.
- Chapter 36, “The DSPEC Package”, describes the symbols available in the `DSPEC` package, which are used for naming and locating definitions.
- Chapter 37, “The EXTERNAL-FORMAT Package”, describes symbols available in the `EXTERNAL-FORMAT` package.
- Chapter 38, “The HCL Package”, describes symbols available in the `HCL` package.
- Chapter 39, “The LINK-LOAD Package”, describes symbols available in the `LINK-LOAD` package. It applies to LispWorks for SPARC Solaris.
- Chapter 40, “The LISPWORKS Package”, describes symbols available in the `LISPWORKS` package.
- Chapter 41, “The LW-JI Package”, describes symbols available in the `LW-JI` package, which allows you to call to and from Java. This chapter describes the Java classes and methods available in LispWorks.
- Chapter 42, “Java classes and methods” describes the Java classes and methods available in LispWorks.
- Chapter 43, “Android Java classes and methods” describes the additional Java classes and methods available in LispWorks for Android Runtime.

- Chapter 44, “The MP Package”, describes symbols available in the **MP** package, giving you access to the multiprocessing capabilities of LispWorks.
- Chapter 45, “The PARSERGEN Package”, describes symbols available in the **PARSERGEN** package, the LispWorks parser generator.
- Chapter 46, “The SERIAL-PORT Package” documents the Serial Port API. This is implemented only in LispWorks for Windows.
- Chapter 47, “The SQL Package” documents symbols used in accessing LispWorks ODBC and SQL functionality.
- Chapter 48, “The STREAM Package” documents the symbols available in the **STREAM** package that provide users with the functionality to define their own streams for use by the standard I/O functions.
- Chapter 49, “The SYSTEM Package”, describes symbols available in the **SYSTEM** package.
- Chapter 50, “Miscellaneous WIN32 symbols”, describes miscellaneous symbols available in the **WIN32** package. It applies only to LispWorks for Windows.
- Chapter 51, “The Windows registry API”, describes the Windows registry API. It applies only to LispWorks for Windows.
- Chapter 52, “The DDE client interface”, describes the Dynamic Data Exchange (DDE) client API. It applies only to LispWorks for Windows.
- Chapter 53, “The DDE server interface”, describes the Dynamic Data Exchange (DDE) server API. It applies only to LispWorks for Windows.
- Chapter 54, “Dynamic library C functions”, describes C functions available in LispWorks dynamic libraries.

Many of these reference chapters should be used in conjunction with corresponding chapters in the user guide section. Reference material for some aspects of LispWorks can be found in other manuals.

## Conventions used for reference entries

Each entry is headed by the symbol name and type, followed by a number of fields providing further details. These fields consist of a subset of the follow-

ing: “Summary”, “Package”, “Signature”, “Method signatures”, “Arguments”, “Values”, “Initial value”, “Superclasses”, “Subclasses”, “Initargs”, “Accessors”, “Readers”, “Description”, “Notes”, “Compatibility notes”, “Examples” and “See also”.

Some symbols with closely-related functionality are coalesced into a single reference entry.

Throughout, variable arguments, slots and return values are italicised. They look *like-this*.

Throughout, exported symbols and example code are printed `like-this`. The package qualifier is usually omitted, unless the symbol is not documented in this manual.

Entries with a long “Description” section usually have as their first field a short “Summary” providing a quick overview of the symbol’s purpose.

The “Package” section shows the package from which the symbol is exported.

The “Signature” section shows the arguments and return values of functions and macros, and the parameters of types.

In a Generic Function entry there may be a “Method signatures” section showing system-defined method signatures.

The “Arguments” and "Values" sections show types of the arguments and return values.

In a Variable entry, the “Initial value” section shows the initial value.

In a Class entry the “Subclasses” section of lists the external subclasses, though not subclasses of those, and the “Superclasses” section lists the external superclasses, though not superclasses of those. The “Initargs” section describes the initialization arguments of the class, though note that initargs of superclasses are also valid. There may be an “Accessors” section listing accessor functions which are both readers and writers, and/or a “Readers” section listing accessor functions which are only readers. Accessor functions access the slot with matching name.

The “Description” section contains the detail of what the symbol does, how each argument is interpreted (and its default value if applicable), and how

each return value is derived. More incidental information may be shown in a “Notes” section.

A few entries have a “Compatibility notes” section describing changes in the symbol’s functionality relative to other LispWorks versions.

Examples are given under the “Examples” heading. Short examples are shown directly. Longer examples are supplied as source files in your LispWorks installation directory under `examples/`. The convenience function `example-edit-file` allows you to open these files in the LispWorks editor. The examples files are in a read-only directory and therefore you should compile them inside the IDE (by the Editor command `Compile Buffer` or the toolbar button or by choosing **Buffer > Compile** from the context menu), so it does not try to write a fasl file. If you want to manipulate an example file or compile it on the disk rather than in the IDE, then you need first to copy the file elsewhere (most easily by using the Editor command `Write File` or by choosing **File > Save As** from the context menu).

Finally, the “See also” section provides links to other related symbols and user guide sections.

## The LispWorks manuals

The LispWorks manual set comprises the following books:

- The Common Lisp HyperSpec contains the specification for Common Lisp itself.
- The *LispWorks User Guide and Reference Manual*—this book—describes the main language-level features and tools available in LispWorks, along with an extensive reference of the functions, macros, variables and classes organized by package. Where LispWorks extends the functionality of a Common Lisp symbol, this is mentioned in Chapter 33, “The COMMON-LISP Package”
- The *LispWorks IDE User Guide* describes the LispWorks IDE, the user interface for LispWorks. This is a set of windowing tools that let you develop and test Common Lisp code more easily and quickly.
- The *LispWorks Editor User Guide* describes the keyboard commands and programming interface to the LispWorks IDE editor tool.

- The *CAPI User Guide and Reference Manual* describes the CAPI. This is a library of classes, functions, and macros for developing graphical user interfaces for your applications. It comprises a tutorial guide to the CAPI and an in-depth reference text.
- The *LispWorks Foreign Language Interface User Guide and Reference Manual* explains how you can use C source code in applications developed using LispWorks.
- The *LispWorks Delivery User Guide* describes how you can deliver working, standalone versions of your LispWorks applications for distribution to your customers.
- *Developing Component Software with CORBA* describes how LispWorks can interoperate with other CORBA-compliant systems.
- The *LispWorks COM/Automation User Guide and Reference Manual* describes a toolkit for using Microsoft COM and Automation in LispWorks for Windows.
- The *LispWorks Objective-C and Cocoa Interface User Guide and Reference Manual* describes APIs for interfacing to Objective-C and Cocoa in LispWorks for Macintosh.
- The *KnowledgeWorks and Prolog User Guide* describes the LispWorks toolkit for building knowledge-based systems. Common Prolog is a logic programming system written in Common Lisp.
- The *LispWorks Release Notes and Installation Guide* explains how to install LispWorks and start it running. It also contains Release Notes describing the new features in this release and any issues that could not be included in the other manuals.

The LispWorks manuals are all available in Portable Documentation Format (PDF). You can use Adobe Reader to browse the PDF documentation online or to print it. Adobe Reader is available for free download from Adobe's web site at [www.adobe.com](http://www.adobe.com).

The LispWorks manuals are also available in HTML format. Commands in the **Help** menu of any of the LispWorks IDE tools give you direct access to the HTML documentation, using your web browser. Details of how to use these commands can be found in the *LispWorks IDE User Guide*.

Please let us know if you find any mistakes in the LispWorks documentation, or if you have any suggestions for improvements.

## Other documentation

The LispWorks manuals do not attempt to describe Lisp itself. For definitive information on Common Lisp, including CLOS, consult the American National Standard X3.226 for Common Lisp. An HTML version of this document is supplied with LispWorks and can be accessed from the **Help** menu.

For information on CLOS, Sonya E. Keene's book *Object-Oriented Programming in Common Lisp: A Programmers' Guide* is very helpful. This book is published by Addison-Wesley.

For an account of Metaobject protocols as well as a detailed study of an implementation of CLOS see Kiczales, des Rivières and Bobrow, *The Art of the Meta-Object Protocol*, published by MIT Press, often referred to as AMOP. The LispWorks MOP mostly conforms to chapters 5 & 6 of AMOP; the differences are mentioned here in Chapter 18, "The Metaobject Protocol".

## Notation and conventions

The LispWorks manuals follow the notation used in *Common Lisp: the Language (2nd Edition)*.

This manual often refers to example files in the LispWorks library, like this:

```
(example-edit-file "ssl/ssl-client")
```

These examples are Lisp source files in your LispWorks installation under `lib/7-1-0-0/examples/`. You can simply evaluate the given form to view the example source file.

Other references such as "... the LispWorks file `foo/bar.lisp`" mean a file `bar.lisp` in a subdirectory `foo` of the LispWorks library directory. Evaluate this form in your LispWorks image to obtain the full path of such a file:

```
(sys:lispworks-file "foo/bar.lisp")
```

# 1

---

---

# Starting LispWorks

Firstly you need LispWorks installed as described in the Release Notes and Installation Guide.

## 1.1 The usual way to start LispWorks

On Microsoft Windows and Mac OS X the simplest way to run LispWorks is that provided in the desktop environment. On Windows you can run LispWorks from the desktop Start menu, or the Start screen on Windows 8. On Mac OS X you can run LispWorks by clicking on the "LW" icon in the Dock. On both these platforms you can create a shortcut to LispWorks and place it somewhere that is convenient for you, such as the Windows 8 taskbar.

On non-Windows and non-Mac OS X systems you start LispWorks by entering the name of the LispWorks executable at a shell prompt.

## 1.2 Passing arguments to LispWorks

Occasionally you may need to start LispWorks with certain arguments. This section describes the most frequent of these occasions.

### 1.2.1 Saving a new image

**Note:** If you use the LispWorks IDE, you may find a saved session more convenient than saving an image as described in this section. See “Saved sessions” on page 182 for more information.

To save a new image "by hand", create a suitable file `save-config.lisp` as described in the section "Saving and testing the configured image" in the *LispWorks Release Notes and Installation Guide*. Such a file should load any desired configuration, modules and application code, and lastly call `save-image`.

Then you run LispWorks with a command line which passes your file as a build script.

On Mac OS X, run Terminal.app to get a shell, and enter a line like this at the prompt:

```
% lispworks-7-1-0-x86-darwin -build /tmp/save-config.lisp
```

On Microsoft Windows, run Command Prompt to get a DOS shell, and enter a line like this:

```
C:\Program Files\LispWorks>lispworks-7-1-0-x86-win32.exe -build  
C:\temp\save-config.lisp
```

On Linux, get a shell and enter a line like this:

```
% lispworks-7-1-0-x86-linux -build /tmp/save-config.lisp
```

On UNIX, get a shell and enter a line like this:

```
% lispworks-7-1-0-sparc-solaris -build /tmp/save-config.lisp
```

When the command exits, a new image has been saved. You can run this new image directly from the command line, or create a shortcut or symbolic link to make it convenient to run.

With all the command lines above, if you perform the task frequently, make a script or a shortcut containing the command line, and run that.

Note that `save-config.lisp` no longer needs to do `(load-all-patches)` because `-build` calls `load-all-patches` automatically in LispWorks 6.1 and later versions. However, if `save-config.lisp` does call `load-all-patches`, this is harmless.

## 1.2.2 Saving a console mode image

To save a LispWorks image which does not start the LispWorks IDE by default, make a script similar to `save-config.lisp` above, but where you call

```
(save-image "my-console-lispworks" :environment nil)
```

The resulting new image, `my-console-lispworks`, can be made to start the LispWorks IDE either by calling `env:start-environment` or by passing `-env` or `-environment` on the command line.

## 1.2.3 Bypassing initialization files

If you do not want to load your personal initialization file, for example to discover if the behavior of LispWorks is due to some setting of yours, pass `-init-` on the command line.

To start LispWorks without loading either the personal or site initialization files, start it like this:

```
lispworks -init - -siteinit -
```

## 1.2.4 Other command line options

Other less commonly-used LispWorks command line arguments are described in “The Command Line” on page 454

# 1.3 Starting the LispWorks Graphical IDE

In LispWorks images shipped on the Windows, Mac OS X, Linux, x86/x64 Solaris, FreeBSD and AIX platforms, the IDE starts automatically by default.

If you have an image saved such that the IDE does not start by default, you can start the IDE by calling the function `env:start-environment`. Such an image is shipped for UNIX platforms.

# 1.4 Using LispWorks with SLIME

Download SLIME from <http://common-lisp.net/project/slime/>

### 1.4.1 Using the Professional/Enterprise Editions with SLIME

To use LispWorks with SLIME it is best to use an image which does not start the LispWorks IDE automatically. You can create such an image with LispWorks Professional or Enterprise Edition. Save it as `~/lw-console` as described in “Saving a non-GUI image with multiprocessing enabled” on page 181.

Configure Emacs to use "`~/lw-console`" as the value of `inferior-lisp-program` as shown in the SLIME README.

### 1.4.2 Using the Personal Edition with SLIME

Start LispWorks Personal Edition, which starts the LispWorks IDE automatically.

Execute these forms in the LispWorks IDE:

```
(load "/path/to/slime/swank-loader")
(swank-loader:init)
(swank:create-server :port 4005)
```

Inside Emacs, `Meta+X slime-connect`. Use the same port given above.

## 1.5 Quitting LispWorks

To quit LispWorks from the LispWorks IDE, use one of the following:

- The menu command **File > Exit** all platforms except Mac OS X.
- The menu command **LispWorks > Quit LispWorks** on Mac OS X.
- The key `Command+Q` on Mac OS X
- The key sequence `ctrl+x ctrl+c` in an editor-based tool such as the Editor or Listener
- A platform/window-manager-specific exit gesture such as clicking a close button on the Podium window
- Call the function `quit`.

To quit LispWorks when running in console mode or via SLIME, simply call `quit`.

# 2

---

## The Listener

The listener is another name for the read-eval-print loop (REPL) which allows you to interactively evaluate Lisp forms and see their output and return values. Lisp programmers typically do incremental development and testing in a listener before saving the working code to disk.

This chapter describes the basic use of a LispWorks listener. You might access this in a terminal (Unix shell) or MS-DOS command window. Alternatively the LispWorks IDE contains a graphical Listener tool which runs a REPL and supports all the functionality described in this chapter, as well as its own graphical features. Please refer to the *LispWorks IDE User Guide* for details specific to the graphical Listener tool.

### 2.1 First use of the listener

LispWorks runs a top-level REPL on startup. The listener by default appears with a prompt. The name of the current package (that is, the value of `cl:*package*`) is printed followed by a positive integer, like this:

```
CL-USER 1 >
```

Enter a Lisp form after the prompt and press `Return`:

```
CL-USER 1 > (print 42)
```

```
42
42
```

```
CL-USER 2 >
```

The first ‘42’ printed is the output of the call to `print`. You see it here because output sent to `*standard-output*` is written to the listener.

The second ‘42’ printed is the return value of the call to `print`.

After the return value a new prompt appears. Notice that it contains ‘2’ after the package name: your successive inputs are numbered. You can now proceed to develop and test pieces of your application code:

```
CL-USER 2 > (defstruct animal species name weight)
ANIMAL

CL-USER 3 > (make-animal :species "Hippopotamus" :name "Hilda"
  :weight 42)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)
```

## 2.2 Standard listener commands

Generally the listener simply evaluates Lisp forms that you enter. However a few keywords, described in the this section, are specially recognized as shortcut for common listener operations.

### 2.2.1 Standard top-level loop commands

<code>:redo</code>	<i>Listener command</i>
--------------------	-------------------------

`:redo &optional command-identifier`

This option repeats a previous input. The *command-identifier* is either a number in the listener’s history list or a symbol or subform in the input to repeat. If *command-identifier* is not supplied, the last input is repeated.

<code>:get</code>	<i>Listener command</i>
-------------------	-------------------------

`:get name command-identifier`

**:get** retrieves a previously-entered input from the listener's history and places it in the variable *name*. The *command-identifier* is the history list number of the input to be retrieved.

**:use***Listener command*

**:use new old &optional command-identifier**

**:use** does a variant of a previous input. *old* matches a symbol or sub-form in the previous input, and is replaced with *new* to construct the new input. If supplied, *command-identifier* is the history list number of the input you want to modify.

**:his***Listener command*

**:his &optional n m**

**:his** produces a list of the input history. If *n* is supplied it should be a positive integer: the last *n* inputs are shown. If *m* is also supplied it should be a positive integer greater than *n*, when inputs numbered *n* through *m* in the history are shown.

**:bug-form***Listener command*

**:bug-form subject &key filename**

**:bug-form** prints a template bug report suitable for sending to Lisp Support. Supply a string *subject*. If you also supply *filename*, the report is printed to the file.

**:help***Listener command*

**:help**

**:help** prints a brief listing of the available listener commands.

**:?***Listener command*

**:?**

`:?` is a synonym for `:help`.

### 2.2.2 Examples

```

CL-USER 4 > :redo
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)

CL-USER 5 > :his

1: (PRINT 42)
2: (DEFSTRUCT ANIMAL SPECIES NAME ...)
3: (MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
4: (MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)

CL-USER 5 > :get make-hilda 3

CL-USER 5 > make-hilda
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)

CL-USER 6 > :use "Henry" "Hilda"
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Henry" :WEIGHT 42)

CL-USER 7 > :bug-form "Too many hippos..." :filename "bug-
report.txt"

```

## 2.3 The listener prompt

The variable `*prompt*` controls the appearance of the listener prompt. See `*prompt*`, page 1163 if you want to alter this.

If the default prompt contains a colon followed by a second positive integer then you are no longer in the top-level loop, but have entered the REPL debugger, as described in “The Debugger” on page 9.

# 3

---

## The Debugger

The debugger is an interactive tool for examining and manipulating the Lisp environment. Within the debugger you have access to not only the interpreter, but also to a variety of debugging tools. The default behavior when any error occurs is to enter the debugger. Users can then trace backwards through the history of function calls to determine how the error arose. They may inspect and alter local variables of the functions on the execution stack, and possibly continue execution by invoking a pre-defined restart (if available) or by forcing any function invocation on the stack to return user-specified values.

When writing an application it is possible to prevent entry to the debugger when an error occurs, by creating condition handlers to take some appropriate action to recover without user intervention. It is also possible to use restarts to specify some default methods of error recovery. The debugger is entered whenever an error is signaled (via a call to `error` or `cerror`) and not handled by an error handler, or it can be explicitly invoked via a call to `break`.

You can use the debugger in REPL mode (that is, in the listener read-eval-print loop) or using the graphical Debugger tool in the LispWorks IDE. This chapter describes the REPL debugger; please refer to the *LispWorks IDE User Guide* for details about the graphical Debugger tool.

The compiler generates information necessary for the use of the debugger during compilation. You can opt for faster compilation, at the expense of

reducing the information available to the debugger, using `toggle-source-debugging`.

## 3.1 Entering the REPL debugger

The following is a simple example.

```
CL-USER 2 > (defun make-a-hippo (name weight)
  (if (numberp weight)
      (make-animal 'hippo name weight)
      (error "Argument to make-a-hippo not a number")))
MAKE-A-HIPPO

CL-USER 3 > (make-a-hippo "Hilda" nil)

Error: Argument to make-a-hippo not a number
1 (abort) Return to level 0.
2 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or :? for
other options.

CL-USER 4 : 1 >
```

The call to `error` causes entry into the debugger. The final prompt in the example contains a 1 to indicate that the top level of the debugger has been entered. The debugger can be entered recursively, and the prompt shows the current level. Once inside the debugger, you may use all the facilities available at the top-level in addition to the debugger commands.

The debugger may also be invoked by using the trace facility to force a break at entry to or exit from a particular function.

The debugger can also be entered by a keyboard interrupt. Keyboard interrupts are generated by the *break gesture*, which varies between the supported systems as follows:

Microsoft Windows

**Ctrl+Break**

GTK and Motif **Meta+Ctrl+C**

**Break** if keyboard has that key. Note that PC keyboards do not have **Break**, only **Ctrl+Break**, which is different. See also `capi:set-interactive-break-gestures`.

Cocoa	<b>Command+Control+,</b> (comma). This is only supported on Mac OS X 10.4 and newer.
-------	--

When the break gesture is used, LispWorks attempts to find a busy process to break. If there is no obvious candidate and the LispWorks IDE is running, then it displays the Process Browser tool.

## 3.2 Simple use of the REPL debugger

Upon entering the debugger as a result of an error, a message describing the error is printed and a number of options to continue (called restarts) are presented. Thus:

```
CL-USER 6 > (/ 3 0)

Error: Division-by-zero caused by / of (3 0)
  1 (continue) Return a value to use
  2 Supply new arguments to use
  3 (abort) return to level 0.
  4 return to top loop level 0.
  5 Destroy process.

Type :c followed by a number to proceed

CL-USER 7 : 1 >
```

To select one of these restarts, enter `:c` (continue) followed by the number of the restart. So in the above example you could continue as follows:

```
CL-USER 7 : 1 > :c 2

Supply first number: 33

Supply second number: 11
3

CL-USER 8 >
```

There are two special restarts, a continue restart and an abort restart. These are indicated by the bracketed word continue or abort at their start. The continue restart can be invoked by typing :c alone. Similarly, the abort restart can be invoked by entering :a. So an alternative continuation of the division example would be:

```
CL-USER 7 : 1 > :c  
Supply a form to be evaluated and used: (+ 4 5)  
9
```

### 3.3 The stack in the debugger

The debugger allows you to examine the state of the execution stack. This consists of a sequence of frames representing active function invocations, special variable bindings, restarts, active catchers, active handlers and system-related code. In particular the execution stack has a call frame for each active function call (that is for each function that has been entered but from which control has not yet returned). The top of the stack contains the most recently created frames (and so the innermost calls), and the bottom of the stack contains the oldest frames (and so the outermost calls). You can examine a call frame to find the function's name, and the names and values of its arguments.

The function call frames displayed are affected by any `hcl:alias` and `hcl:invisible-frame` declarations. See `declare`, page 651 for the details.

Catch frames are established by using the special form `catch`, and exist to receive throws to the matching tag. Restart frames correspond to restarts that have been set up, and handler frames correspond to the error handlers currently active. Binding frames are formed when special variables are bound. Open frames are established by the system. By default only the catch frames and the call frames are displayed. However the remaining types of frame are displayed if you set the appropriate variables (see Section 3.6 on page 23).

Within the debugger there are commands to examine a stack frame, and to move around the stack. These are explained in the following section. Typing `:help` in the debugger also produces a command listing.

One of the most useful features is that you can access a local variable in the current frame simply by entering its name as shown in the backtrace. See step 7 in “Example debugging session” on page 21.

## 3.4 REPL debugger commands

This section describes commands specific to the debugger. In the debugger, you can also do anything that you can do in the top-level loop including evaluation of forms and the standard listener commands.

Upon entry to the debugger the implicit current stack frame is set to the top of the execution stack. The debugger commands allow you to move around the stack, to examine the current frame, and to leave the debugger. The commands are all keywords, and as such case-insensitive, but are shown here in lower case for clarity.

You can get brief help listing these commands by entering `:?` at the debugger prompt.

### 3.4.1 Backtracing

A backtrace is a list of the stack frames starting at the current frame and continuing down the stack. The backtrace thus displays the sequence by which the functions were invoked, starting with the most recent. For instance:

### 3 The Debugger

```
CL-USER 10 > (defun function-1 (a b c)
                  (function-2 (+ a b) c))
FUNCTION-1

CL-USER 11 > (defun function-2 (a b)
                  (function-3 (+ a b)))
FUNCTION-2

CL-USER 12 > (defun function-3 (a) (/ 3 (- 111 a)))
FUNCTION-3

CL-USER 13 > (function-1 1 10 100)

Error: Division-by-zero caused by / of (3 0)
1 (continue) Return a value to use
2 Supply new arguments to use
3 (abort) return to level 0.
4 return to top loop level 0.
5 Destroy process.

Type :c followed by a number to proceed

CL-USER 14 : 1 > :bq 10

SYSTEM::DIVISION-BY-ZERO-ERROR <- / <- FUNCTION-3
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- FUNCTION-2
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- FUNCTION-1
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- SYSTEM:::%INVOKE <-
SYSTEM::%EVAL

CL-USER 15 : 1 >
```

In the above example the command to show a quick backtrace was used (`:bq`). Instead of showing each stack frame fully, this only shows the function name associated with each of the call frames. The number 10 following `:bq` specifies that only the next ten frames should be displayed rather than continuing to the bottom of the stack.

**:b**

*Debugger command*

`:b &optional verbose m`

This is the command to obtain a backtrace from the current frame. It may optionally be followed by `:verbose`, in which case a fuller description of each frame is given that includes the values of the arguments to the

function calls. It may also be followed by a number (*m*), specifying that only that number of frames should be displayed.

**:bq**

*Debugger command*

**:bq m**

This produces a quick backtrace from the current position. Only the call frames are included, and only the names of the associated functions are shown. If the command is followed by a number then only that many frames are displayed.

### 3.4.2 Moving around the stack

On entry to the debugger the current frame is the one at the top of the execution stack. There are commands to move to the top and bottom of the stack, to move up or down the stack by a certain number of frames, and to move to the frame representing an invocation of a particular function.

**:>**

*Debugger command*

This sets the current frame to the one at the bottom of the stack.

**:<**

*Debugger command*

This sets the current frame to the one at the top of the stack.

**:p**

*Debugger command*

**:p [m | fn-name | fn-name-substring]**

By default this takes you to the previous frame on the stack. If it is followed by a number then it moves that number of frames up the stack. If it is followed by a function name then it moves to the previous call frame for that function. If it is followed by a string then it moves to the previous call frame whose function name contains that string.

**:n** *Debugger command*

**:n [m | fn-name | fn-name-substring]**

Similar to the above, this goes to the next frame down the stack, or *m* frames down the stack, or to the next call frame for the function *fn-name*, or to the next call frame whose function name contains *fn-name-substring*.

### 3.4.3 Miscellaneous commands

**:v** *Debugger command*

This displays information about the current stack frame. In the case of a call frame corresponding to a compiled function the names and values of the function's arguments are shown. Closure variables (either from an outer scope or used by an inner scope) and special variables are indicated by {closing} or {special} as in this session:

```

CL-USER 32 > (compile (defun foo (*zero* one two)
                           (declare (special *zero*))
                           (list (/ one *zero*)) #'(lambda () one)
                           two))
FOO
NIL
NIL

CL-USER 33 > (foo 0 1 2)

Error: Division-by-zero caused by / of (1 0).
1 (continue) Return a value to use.
2 Supply new arguments to use.
3 (abort) Return to level 0.
4 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or :? for
other options.

CL-USER 34 : 1 > :n foo
Call to FOO

CL-USER 35 : 1 > :v
Call to FOO {offset 114}
*ZERO* {Special} : 0
ONE {Closing} : 1
TWO : 2

CL-USER 36 : 1 >

```

For an interpreted function the names and values of local variables are also shown.

If the value of an argument is not known (perhaps because the code has been compiled for speed rather than other considerations), then it is printed as the keyword `:dont-know`.

:l

*Debugger Command*

`:l [m | var-name | var-name-substring]`

By default this prints a list of the values of all the local variables in the current frame. If the command is followed by a number then it prints the value of the `m`'th local variables (counting from 0, in the order shown

by the `:v` command). If it is followed by a variable name *var-name* then it prints the value of that variable (note that the same effect can be achieved by just entering the name of the variable into the Listener). If it is followed by a string *var-name-substring* then it prints the value of the first variable whose name contains *var-name-substring*.

In all cases, `*` is set to the printed value.

`:error`

*Debugger command*

This reprints the message which was displayed upon entry to the current level of the debugger. This is typically an error message and includes several continuation options.

`:cc`

*Debugger command*

`:cc &optional var`

This returns the current condition object which caused entry to this level of the debugger. If an optional *var* is supplied then this must be a symbol, whose symbol-value is set to the value of the condition object.

`:ed`

*Debugger command*

This allows you to edit the function associated with the current frame. If you are using TAGS, you are prompted for a TAGS file.

`:all`

*Debugger command*

`:all &optional flag`

This option enables you to set the debugger option to show all frames (if *flag* is non-nil), or back to the default (if *flag* is nil). By default, *flag* is t.

See also `set-debugger-options`.

**:lambda***Debugger command*

This returns the lambda expression for an anonymous interpreted frame. If the expression is not known, then it is printed as the keyword :**don't-know**

**:func***Debugger command*

**:func** &optional *disassemble-p*

This returns (and sets \*) the function object of the current frame. This is especially useful for the call frame of functions that are not the symbol function of some symbols, for example closures and method functions.

If *disassemble-p* is true, **:func** first disassembles the function, and then returns it and sets \*. The default value of *disassemble-p* is **nil**.

**:func** is applicable only in call frames.

**:if***Debugger command*

This command prints symbols from other packages corresponding to the symbol that was called, but could not be found, in the current package. Any such symbols are also offered as restarts when you first enter the debugger.

```
NEW 21 > (initialize-graphics-port)

Error: Undefined function INITIALIZE-GRAFICS-PORT called with
arguments ().

  1 (continue) Try invoking INITIALIZE-GRAFICS-PORT again.
  2 Return some values from the call to INITIALIZE-GRAFICS-PORT.
  3 Try invoking GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT with the
same arguments.
  4 Set the symbol-function of INITIALIZE-GRAFICS-PORT to the
symbol-function of GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT.
  5 Try invoking something other than INITIALIZE-GRAFICS-PORT
with the same arguments.
  6 Set the symbol-function of INITIALIZE-GRAFICS-PORT to
another function.
  7 (abort) Return to level 0.
  8 Return to top loop level 0.

Type :c followed by a number to proceed or type :? for other
options

NEW 22 : 1 > :lf
Possible candidates are (GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT)
GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT

NEW 23 : 1 >
```

### 3.4.4 Leaving the debugger

You may leave the debugger either by taking one of the continuation options initially presented, or by explicitly specifying values to return from one of the frames on the stack.

**:a** *Debugger command*

This selects the **:abort** option from the various continuation options that are displayed when you enter the current level of the debugger.

**:c** *Debugger command*

**:c &optional m**

If this is followed by a number then it selects the option with that number, otherwise it selects the **:continue** option.

**:ret***Debugger command***:ret value**

This causes *value* to be returned from the current frame. It is only possible to use this command when the current frame is a call frame. Multiple values may be returned by using the **values** function. So to return the values 1 and 2 from the current call frame, you could type

**:ret (values 1 2)****:res***Debugger command***:res m**

Restarts the current frame. If *m* is **nil**, you are prompted for new arguments which should be entered on one line, separated by whitespace. If *m* is true or is not supplied, the original arguments to the frame are used.

**:top***Debugger command*

Aborts to the top level of the debugger. A synonym is **:a :t**.

### 3.4.5 Example debugging session

This section presents a short interactive debugging session. It starts by defining a routine to calculate Fibonacci Numbers, and then erroneously calls it with a string.

1. First, define the **fibonacci** function shown below in a listener.

```
(defun fibonacci (m)
  (let ((fib-n-1 1)
        (fib-n-2 1)
        (index 2))
    (loop
      (if (= index m) (return fib-n-1))
      (incf index)
      (psetq fib-n-1 (+ fib-n-1 fib-n-2)
            fib-n-2 fib-n-1))))
```

2. Next, call the function as follows.

```
(fibonacci "turtle")
```

The system generates an error, since `c1 :=` expects its arguments to be numbers, and displays several continuation options, so that you can try to find out how the problem arose.

3. Enter `:bb` at the debugger prompt to obtain a full backtrace.

Notice that the problem is in the call to `fibonacci`.

You should have passed the length of the string as an argument to `fibonacci`, rather than the string itself.

4. Attempt to calculate this value now, by typing the following form at the debugger prompt.

```
(length "turtle")
```

You intended to call `fibonacci` with the length of the string, but entered `length` incorrectly. This takes you into the second level of the debugger. Note that the continuation options from your entry into the top level of the debugger are still displayed, and are listed after the new options. You can select any of these options.

5. Enter `:a` to abort one level of the debugger.

6. Enter `:error` to remind yourself of the original error that you need to handle. You need to fix the value passed as the second argument to `fibonacci`.

7. Enter `:n fibonacci` to move to the stack frame for the call to `fibonacci`.

8. Enter `:v` to display variable information about this stack frame:

```
Interpreted call to FIBONACCI:  
  M      : "turtle"  
  INDEX   : 3  
  FIB-N-2 : 1  
  FIB-N-1 : 2
```

You need to set the value of the variable `m` to be the length of the string `"turtle"`, rather than the string itself.

9. Enter this form:

```
(setq m (length "turtle"))
```

In order to get the original computation to resume using the new value of *m*, you still need to handle the original error.

**10.** Enter `:error` to remind yourself of the original error condition.

You can handle this error by returning `nil` from the call to `c1:=`, which is the result that would have been obtained if *m* had been correctly set initially.

**11.** Enter `:c` to invoke the `continue` restart, which in this case requires you to return a value to use.

**12.** When prompted for a form to be evaluated, enter `nil`.

This causes execution to continue as desired. Notice that the correct result `8` is returned.

## 3.5 Debugger troubleshooting

Code which modifies the readable case of the readtable can hinder debugger interaction. This is because standard commands entered as lowercase `:a` for example will not be recognized if the readtable case is `:preserve` or `:down-case`.

You can use `with-debugger-wrapper` together with `with-standard-io-syntax` to enable the debugger to recognize such input if the code in *body* should enter the debugger, like this:

```
(defun my-debugger-wrapper (func condition)
  (with-standard-io-syntax
    (funcall func condition)))

(dbg:with-debugger-wrapper
  'my-debugger-wrapper
  (let ((*readtable* (some-modified-readtable)))
    body))
```

## 3.6 Debugger control variables

`cl:*debug-io*`

The value of this variable is the stream which the debugger uses for its input and output.

`dbg:*debug-print-length*`

The value to which `cl:*print-length*` is bound during output from the debugger.

**`dbg:*debug-print-level*`**

The value to which `cl:*print-level*` is bound during output from the debugger.

**`dbg:*hidden-packages*`**

This variable should be bound to a list of packages. The debugger suppresses symbols from these packages (so, for example, it does not display call frames for functions in these packages).

**`dbg:*print-binding-frames*`**

This variable controls whether binding frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `set-debugger-options` which may be more convenient.

**`dbg:*print-catch-frames*`**

This variable controls whether catch frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `set-debugger-options` which may be more convenient.

**`dbg:*print-handler-frames*`**

This variable controls whether handler frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `set-debugger-options` which may be more convenient.

**`dbg:*print-restart-frames*`**

This variable controls whether restart frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `set-debugger-options` which may be more convenient.

.

## 3.7 Remote debugging

Remote debugging allows you to debug a LispWorks process that is running on one machine using a LispWorks IDE that is running on another machine. It is intended to make it easier to debug applications running on machines that do not have the LispWorks IDE, mainly mobile device applications on iOS and Android, but also applications running on servers where you cannot run the LispWorks IDE.

In the discussion below, the process being debugged is referred to as the "client", and the process running the LispWorks IDE is referred to the "IDE".

With remote debugging you can:

- Make the client, when it enters the debugger, open a GUI debugger in the IDE. The GUI debugger behaves like an ordinary GUI debugger, but the data it displays is from the client, and input into its Listener pane is read and evaluated by the client.
- Open a Listener in the IDE, where reading and evaluating input is done by the client. This can be done either by calling `start-remote-listener` on the client side, or `ide-open-a-listener` on the IDE side.
- Inspect remote objects, by using the Inspector as usual on the IDE side, or `remote-inspect` on the client side.
- Evaluate forms on the client side from the Editor on the IDE side.

When you look at the source code from an IDE tool that is displaying client side data (for example by using the **Find Source** menu item) or look at the class of a remote object, the IDE finds the matching source or class on its side. You need to ensure that the IDE and the client sides have the same sources and class definitions for that to work.

Remote debugging is based on "connections", which are implemented on top of streams connecting the two sides. In normal usage, LispWorks will open a TCP socket stream for a connection, but you can also create connections with your own streams or sockets.

A LispWorks process that has loaded the remote debugging module can be connected to several IDE processes simultaneously, and any IDE process can be connected to several clients. The same IDE process can act as the client side

and the IDE side at the same time. However, the most common usage is expected to be one client and one IDE, and the interface is designed towards this simple usage.

Communication across the connection is architecture-independent, and either side can be any architecture. It relies on there being a working Common Lisp reader.

The client side should load the client code by calling:

```
(require "remote-debugger-client")
```

Note that if the client is a delivered application, the call to `require` needs to happen at load time, before calling `deliver`. On the IDE side, the module "remote-debugger-full" (which includes "remote-debugger-client") is loaded automatically when needed.

### 3.7.1 Simple usage

In the simple usage scenario, you have one IDE and one client. To create the connection between them, you need to tell LispWorks how to create the TCP socket stream, which requires one side to be a TCP server, and the other side to have the address (or name) of the server-side machine to connect to. Therefore, in the simple case you will need to make a function call on both sides. Once you perform the two function calls, you can use most of the power of remote debugging.

There are two ways to specify the connection: one with the IDE acting as the TCP server, and one with the client acting as the TCP server.

#### 3.7.1.1 Using the IDE as the TCP server

On the IDE side, you should call:

```
(dbg:start-ide-remote-debugging-server)
```

On the client side, you should call:

```
(dbg:configure-remote-debugging-spec "ide-hostname")
```

After making these calls, whenever the debugger is entered on the client side, it will automatically display a GUI debugger on the IDE side. In addition, calls

to `start-remote-listener` and `remote-inspect` from the client side will automatically display tools on the IDE side.

These functions use TCP port 21101 by default (the initial value of `*default-ide-remote-debugging-server-port*`).

By default, `configure-remote-debugging-spec` delays opening the connection until it is actually needed (by entering the debugger, or a call to `start-remote-listener` or `remote-inspect`).

Note that within the LispWorks IDE, you can make the call to `start-ide-remote-debugging-server` using the **Start IDE Remote Debugging Server** button in the **Preferences** dialog **Debugger** options **Remote** tab.

### 3.7.1.2 Using the client as the TCP server

On the client side you should call:

```
(dbg:start-client-remote-debugging-server)
```

On the IDE side you should call:

```
(dbg:ide-connect-remote-debugging "client-hostname")
```

The call on the IDE side opens a connection, which the client will use when entering the debugger and in calls to `start-remote-listener` and `remote-inspect`.

These functions use TCP port 21102 by default (the initial value of `*default-client-remote-debugging-server-port*`).

Note that within the LispWorks IDE, you can make the call to `ide-connect-remote-debugging` using the **Connect To Debugging Client** button in the **Preferences** dialog **Debugger** options **Remote** tab.

## 3.7.2 The client side of remote debugging

The client side remote debugging API is intended to minimize the amount of work you need to do for simple configurations.

Once you have either specified the connection by calling `configure-remote-debugging-spec` on the client side and called `start-ide-remote-debugging-server` on the IDE side, or called `start-client-remote-debugging-`

`server` on the client side and the IDE has connected to it using `ide-connect-remote-debugging`, entering the debugger automatically opens a Debugger window on the IDE side (unless you are already inside a Remote Listener or Remote Debugger).

If you want to open a Remote Listener on the IDE side from the client side, you can call `start-remote-listener`. Also, you can call `remote-inspect` on the client side to inspect an object on the IDE side.

The interface allows you to have more complex configurations, as detailed by `configure-remote-debugging-spec`, `create-client-remote-debugging-connection` and `start-client-remote-debugging-server`.

### 3.7.3 The IDE side of remote debugging

The behavior of the Debugger, Listener and Inspector tools is described in the *LispWorks IDE User Guide*.

Remote Debugger windows are opened automatically when the client side enters the debugger.

Remote Listener windows are opened on request, either by using the IDE's menus, by calling `ide-open-a-listener`, or by calling `ide-connect-remote-debugging` with `:open-a-listener t` (or from the client side by `start-remote-listener`).

The Inspector inspects a remote object when you tell it to inspect in the same way as you would tell it to inspect an ordinary object (typically from the Debugger or Listener), or by calling `remote-inspect` on the client side.

#### 3.7.3.1 Accessing client side objects on the IDE side

Remote (client side) values can be used on the IDE side and the type of object affects how it is represented.

Remote numbers and characters are represented on the IDE side as their actual IDE side values.

Remote strings are represented on the IDE side as IDE side strings, which are copies of the string of the same element type. Note that, as a result, two separate occurrences in the IDE of the same client side string are not necessarily

the same object, and that modifying the characters in these strings does not affect the string on the client side.

Most other remote objects are represented in the IDE by remote handles (see below for exceptions). Handles are specific to a connection, so accessing the same remote object in the IDE multiple times over the same connection will always use the same (by `eq`) handle. However, accessing the same client object through different connections will use different handles, which are not equal at all, and there is no way to find if two handles from different connections refer to the same remote object.

Remote handles are printed like this:

```
#<Remote ... >
```

where the ... is the printing of the remote object by the client side.

Handles are opaque objects. The predicate `remote-object-p` can be used to check if an object is a remote object, and `remote-object-connection` returns the connection that the handle is associated with. If two handles are associated with the same connection, then they are `eq` if and only if they refer to the same object on the client side.

The generic function `get-inspector-values` has a method that specializes on handles to invoke `get-inspector-values` on the client side and return the results. Note that `get-inspector-values` also returns a setter, which allows you to set values inside the client's object. This method makes the IDE Inspector and the CL functions `inspect` and `describe` work on remote handles.

Apart from the interface in the previous paragraphs, there is no useful way to access handles on the IDE side. However, you can access the underlying remote object by using `ide-eval-form-in-remote` or `ide-funcall-in-remote`, by sending a form containing the handle. For example, assuming the value of `my-remote-simple-vector` is a remote handle for a simple-vector, you can read its first element by:

```
(dbg:ide-eval-form-in-remote `(svref ,my-remote-simple-vector 0))
```

This will call `svref` on the client's object that `my-remote-simple-vector` is a handle for, because the client side call receives the underlying object rather than the handle.

Each call to `ide-eval-form-in-remote` and `ide-funcall-in-remote` is associated with a specific connection, and only remote objects that are associated with the connection can be used in form arguments. Trying to use remote objects that are associated with another connection signals an error.

LispWorks represents certain client side conses/symbols as conses/symbols on the IDE side in cases where there is no need to access the remote object. For example, the lists that `get-inspector-values` returns are IDE side conses, and the symbols in the slot-names list are IDE side symbols (for symbols in packages that exist on the IDE side). By default, `ide-eval-form-in-remote` and `ide-funcall-in-remote` return handles to the values returned by the form, except for numbers, characters, strings and the top-level of lists. They have a keyword `:encoded-result` which gives you some control over whether the values are returned as handles or not.

When displaying the source code of a function, LispWorks uses source location information on the IDE side to find the source file. That means that the IDE side needs to have the same source files loaded as the client side. To find a subform inside the definition of a function, the debugger uses the information from the client side, which must be compiled with source-level-debugging (and kept if it is delivered) for this to work.

Invoking the Class Browser in the IDE for a remote object handle shows the class on the IDE side that has the same `class-name` as the class of the object on the client side. Calling `class-of` (and `type-of`) on the IDE side on a remote object handle return the internal class (and class name) of remote handles, which you should not be accessing.

### 3.7.3.2 Controlling the client side from the IDE side

The functions `ide-eval-form-in-remote` and `ide-funcall-in-remote` can be used to call functions on the client side (`ide-eval-form-in-remote` is used by the editor commands).

The function `ide-set-remote-symbol-value` can be used to set the global value of a symbol on the client side, which is a common operation. It is equivalent to calling `ide-funcall-in-remote` with `set`.

The function `ide-attach-remote-output-stream` can be used to create an output stream on the client side, such that any output into it will go to a

stream on the IDE side. It returns a remote object handle for the client side stream, which can then be used it calls to `ide-eval-form-in-remote` etc.

## 3.7.4 Troubleshooting

The sections below describe some unexpected problems that you might encounter when using remote debugging and suggest ways to solve them.

### 3.7.4.1 Failing to open connections

There are some basic things to check first.

1. Make sure that you use the right pair of functions. Either:

`start-client-remote-debugging-server` on the client side and `ide-connect-remote-debugging` on the IDE side.

Or:

`configure-remote-debugging-spec` on the client side and `start-ide-remote-debugging-server` on the IDE side.

When using `start-client-remote-debugging-server` and `ide-connect-remote-debugging`, `start-client-remote-debugging-server` must be called first.

When using `configure-remote-debugging-spec` and `start-ide-remote-debugging-server`, `start-ide-remote-debugging-server` must be called before the connection is opened by the client. However, by default, `configure-remote-debugging-spec` delays opening the connection until it is needed so can be called first.

2. Check that you are either using the default port numbers, or you have changed them to the same number on both sides.
3. Check that you have the correct hostname in `configure-remote-debugging-spec` or `ide-connect-remote-debugging`.
4. On Android, you need to add the INTERNET permission to the application. The Android example has the line commented out in its Manifest file (`example-file "android/OthelloDemo/AndroidManifest.xml"`).

5. Check that the two machines can connect by TCP (for example, there is no firewall blocking connections).
6. Check that the functions you use return the expected values.
7. Specify the `:log-stream` argument for both sides, and check if anything is written to it.

If you cannot find the problem, then check that the connection works at the TCP level.

- If you run the client as the TCP server, evaluate the following on the client side:

```
(setq *log-stream* <somewhere-that-you-can-see-it>

(comm:start-up-server
 :function #'(lambda (socket)
           (format *log-stream* "Connected from ~a~%" 
                   (comm:get-socket-peer-address socket))
           (finish-output *log-stream*)))
 :service dbg:*default-client-remote-debugging-server-port*)
```

and then on the IDE side evaluate:

```
(comm:open-tcp-stream "<client-hostname>"
                      dbg:*default-client-remote-debugging-server-port*)
```

The call to `open-tcp-stream` should return a stream, and the "Connected from" message should be printed to `*log-stream*` on the client side.

- If you run the IDE as the TCP server, evaluate the following on the IDE side:

```
(comm:start-up-server
 :function #'(lambda (socket)
           (format mp:*background-standard-output*
                  "Connected from ~a~%" 
                  (comm:get-socket-peer-address socket))
           (finish-output mp:*background-standard-output*)))
 :service dbg:*default-ide-remote-debugging-server-port*)
```

and then on the client side evaluate:

```
(comm:open-tcp-stream "<ide-hostname>"
                      dbg:*default-ide-remote-debugging-server-port*)
```

The call to `open-tcp-stream` should return a stream, and the "Connected from" message should be printed to **Output** tab of the Listener or Editor in the IDE.

If you cannot connect as above then you need to fix the configuration of your machines to make it work. If you can connect as above, but the remote debugging does not connect after you did all the checks then contact LispWorks support for help.

### 3.7.4.2 The Inspector does not show slots in a remote object

The most likely explanation for this is that the underlying connection was closed. Check if the remote object prints with "{closed connection}".

## 3.7.5 Advanced usage - multiple connections

### 3.7.5.1 Client side connection management

By default, the connection opened by the client side functions is reused whenever a connection is needed. This is normally all that is required, but sometimes it is useful to have a better control.

The client has a default connection (a global value), and a switch that enables using the default connection (the enabling switch). Both `configure-remote-debugging-spec` and `start-client-remote-debugging-server` have keyword arguments `:setup-default` and `:enable`, which control setting the default connection, and whether to enable using it. The default for both is true. The default connection and switch are used by the APIs that need a connection (mainly when the debugger is entered, but also `remote-inspect` and `start-remote-listener`), so by default the connection that was opened last is used.

The value of the enabling switch can be set globally by `set-remote-debugging-connection` or in a dynamic extent by `with-remote-debugging-connection`. These functions also allow you to specify a specific connection to use, rather than the default. Note that `with-remote-debugging-connection` and `set-remote-debugging-connection` do not affect the default connection, only the enabling switch.

The function `set-default-remote-debugging-connection` can be used to set the default connection.

`start-client-remote-debugging-server` and `configure-remote-debugging-spec` take also a keyword `:open-callback`, which specifies a callback that is called whenever a connection is created. You can use this callback to store the connection somewhere for later use, for example in a call to `set-default-remote-debugging-connection`, `set-remote-debugging-connection` or `with-remote-debugging-connection`.

The value of the `:setup-default` keyword to `configure-remote-debugging-spec` can also be `:delayed`, which means that the connection is not opened immediately, but when it is opened, it is set as the default.

When the debugger is entered, it first checks the value of the enabling switch. If it is set to a connection then that connection is used. If it is set to `t`, then the default connection is used. Otherwise, it checks if a host was configured (globally by `configure-remote-debugging-spec` or in a dynamic extent by `with-remote-debugging-spec`) and tries to open a connection to it. If that succeeds, it decides according to the `:setup-default` and `:enable` arguments whether to set the default connection and the enabling switch, and then use this connection. If `:setup-default` is `nil`, then the connection is closed when the Remote Debugger is closed.

When a connection is closed, all remote object handles in the IDE that were created using it become invalid. For example, if you use `configure-remote-debugging-spec` with `:setup-default nil`, and later the Remote Debugger was raised and you inspected an argument of a function and then closed the Remote Debugger, then the Inspector will fail to access slots in this object. For this reason, it is usually better to have a permanently open default connection, so the Inspector can be still be used after the Remote Debugger has been closed. A single connection is also more efficient, but the effect of this is small.

`start-remote-listener` behaves the same as the debugger when it tries to find a connection.

`remote-inspect` first checks if it can use an existing connection the same way as the debugger. However, if it cannot, it tries to use a connection used previously by an Inspector. If this does not work, it tries the default connection (if any) even if the enabling switch is `nil`, and if all these fail, it opens a connec-

tion using the configured host if any, and remembers it for the next time (unless configured to set this connection as the default). The Inspector behaves differently to the Debugger/Listener is because there is no obvious place where a temporary connection should be closed in the case of the Inspector, compared to the Debugger and Listener where closing the GUI tool is the natural place to close the connection if it is temporary.

In the simplest usage, you will have one connection that is used for everything. The next level of complexity is to have one connection, but control dynamically whether to use it or not, either globally by calls to `set-remote-debugging-connection`, or in a dynamic extent using `with-remote-debugging-connection`.

For more complex usage, you can use the `:open-callback` to record the connections that you have opened, and then use them in `set-default-remote-debugging-connection` or `set-remote-debugging-connection` or `with-remote-debugging-connection` to tell the debugger/listener/inspector which connection to use.

The functions described in “Common (both IDE and client) connection functions” on page 36 can also be used on the client side.

### 3.7.5.2 IDE side connection management

Normally you do not need to manage remote debugging connections on the IDE side, but sometimes it may be useful.

`ide-list-remote-debugging-connections` returns a list of connections.

`ide-find-remote-debugging-connection` can be used to find a connection. This is used by default by the IDE side functions that need a connection (`ide-eval-form-in-remote`, `ide-funcall-in-remote`, `ide-set-remote-symbol-value` and `ide-attach-remote-output-stream`), and the Editor commands.

`ide-set-default-remote-debugging-connection` can be used to set the default connection, which is what the Editor commands use, and affects what `ide-find-remote-debugging-connection` returns.

You can get the connection from a remote object handle by using `remote-object-connection`.

The functions described in “Common (both IDE and client) connection functions” on page 36 can also be used on the IDE side.

### 3.7.5.3 Common (both IDE and client) connection functions

You can close a connection by using `close-remote-debugging-connection`. Closing a connection causes the other side to be closed too. Closing the default connection causes the default to be set to `nil`.

You can use `ensure-remote-debugging-connection` to check if a connection is alive. `ensure-remote-debugging-connection` can be called with any object and returns `nil` for any non-connection object or a connection object that is closed.

You can use `remote-debugging-connection-add-close-cleanup` to add a “cleanup”, which is a callback function that is called when the connection is closed, and `remote-debugging-connection-remove-close-cleanup` to remove a previously added cleanup.

The function `remote-debugging-connection-peer-address` can be used to check what machine is on the other side.

The function `remote-debugging-connection-name` can be used to find the name of a connection.

Each opened connection has a dedicated Lisp process that handles communications through it, which you can see by listing processes using `(mp:ps)` or in the Process Browser tool. The name of the connection appears in the name of the process. You can forcibly close a connection by using `process-terminate` on the process or from the Process Browser.

# 4

---

# The REPL Inspector

LispWorks provides two inspectors. One is for use with the LispWorks IDE, and is described in the *LispWorks IDE User Guide*. The other is the REPL inspector, which uses a stream interface, and can be used on any terminal (in particular within the LispWorks IDE Listener tool). Both inspectors allow you to traverse complex data structures interactively and to destructively modify components of these structures. However, the two inspectors are quite different. No attempt has been made to make their usage compatible and instead each inspector is designed to exploit to the full the particular environment facilities available.

The REPL inspector provides a simple inspector facility which can be used on a stream providing line breaks as the only type of formatting. It is built on top of the `describe` function which is briefly described below and modifies the top level loop in a similar way to the debugger (see Chapter 3, “The Debugger”).

## 4.1 Describe

The function `describe` displays the slots of composite data structures in a manner dependent on the type of the object. The slots are labeled with a name where appropriate, or otherwise with a number.

The example below shows the result of calling `describe` on a simple list.

```

USER 7 > (setq countries '("Chile" "Peru" "Paraguay"
                           "Brazil"))
          ("Chile" "Peru" "Paraguay" "Brazil")

USER 8 > (describe countries)
("Chile" "Peru" "Paraguay" "Brazil") is a CONS
[0] : "Chile"

[1] : "Peru"

[2] : "Paraguay"

[3] : "Brazil"

```

`describe` describes slots recursively up to a limit set by the special variable `*describe-level*`. Note that only arrays, structures and conses are printed recursively. The slots of all other object types are only printed when at the top level of `describe`.

`*describe-level*` has an initial value of 1.

The symbols `*describe-print-level*` and `*describe-print-length*` are similar in effect to `*trace-print-level*` and `*trace-print-length*`. They control, respectively, the depth to which nested objects are printed (initial value 10), and the number of components of an object which are printed (initial value 10).

To customize `describe`, define new methods on the generic function `describe-object`.

## 4.2 Inspect

The function `inspect` is an interactive version of `describe`. It displays objects in a similar way to `describe`. Entering the inspector causes a new level of the top loop to be entered with a special prompt indicating that the inspector has been entered and showing the current inspector level.

In the modified top loop, if you enter a slot name, that slot is inspected and the current object is pushed onto an internal stack of previously inspected objects. The special variables `$`, `$$`, and `$$$` are bound to the top three objects on the inspector stack.

The following keywords are treated specially as commands by the inspector.

Table 4.1 Inspector commands

Command	Meaning
<code>:cv</code>	Display current values of control variables.
<code>:d</code>	Display current object.
<code>:dm</code>	Display more of current object.
<code>:dr</code>	Display rest of current object.
<code>:h</code>	Display help on inspector commands.
<code>:i m</code>	Recursively invoke a new inspector. <i>m</i> is an object to inspect.
<code>:m</code>	Change the inspection mode — see Section 4.3 on page 40.
<code>:q</code>	Quit current inspector.
<code>:s n v</code>	Sets slot <i>n</i> to value <i>v</i> .
<code>:sh</code>	Show inspector stack.
<code>:u int</code>	Undo last inspection. If you supply an optional integer argument, <i>int</i> , then the last <i>int</i> inspections are undone.
<code>:ud</code>	Undo last inspection and redisplay current object.

You can get brief help listing these commands by entering `:?` at the inspector prompt.

The control variables `*inspect-print-level*` and `*inspect-print-length*` are similar to `*describe-print-level*` and `*describe-print-length*` (see above).

`:dm` displays more slots of the current object. If the object has more than `*describe-length*` slots, then the first `*describe-length*` will be printed, followed by an ellipsis and then

`(:dm or :dr for more)`

If you enter the command `:dm` at the prompt it displays the next `*describe-length*` slots, and if you enter `:dr` it displays all the remaining slots. This

only works on the last inspected object, so if you recursively inspect a slot and come back, `:dm` does not do anything useful. Typing `:d` lets you view the object again.

`:ud` is equivalent to typing `:u` followed by `:d`.

### 4.3 Inspection modes

The `:m` command displays and changes the current inspection mode for an inspected value. The session below demonstrates how it works:

```
CL-USER 128 > (inspect "a
string with
newlines in it")

"a
string with
newlines in it" is a SIMPLE-BASE-STRING
0      #\a
1      #\Newline
2      #\s
3      #\t
4      #\r
5      #\i
6      #\n
7      #\g
8      #\Space
9      #\w
10     #\i
11     #\t
12     #\h
13     #\Newline
14     #\n
15     #\e
16     #\w
17     #\l
18     #\i
19     #\n ..... (:dm or :dr for more)

CL-USER 129 : Inspect 1 > :m
* 1. SIMPLE-STRING
  2. LINES
```

The `:m` produces an enumerated list of inspection modes for this value.

The asterisk next to

```
* 1. SIMPLE-STRING
```

means that SIMPLE-STRING is the current inspection mode.

You can change mode by typing :m followed by the name or number of another mode. To change to LINES mode:

```
CL-USER 130 : Inspect 1 > :m 2

" a
string with
newlines in it" is a SIMPLE-BASE-STRING
0      a
1      string with
2      newlines in it
```

### 4.3.1 Hash table inspection modes

There are five hash table inspection modes. They can be accessed in either the LispWorks IDE Inspector tool or the REPL inspector.

A brief introduction to the representation of hash tables is necessary so that you can fully understand what you gain from the new modes.

Internally, a hash table is a structure containing, among other things,

- a big vector
- size and growth information
- accessing functions.

When keys and values are added to the table, sufficiently similar keys are converted into the same index in the vector. When this happens, the similar keys and values are kept together in a chain that hangs off this place in the vector.

The different inspection modes provide views of different pieces of this structure:

<b>HASH-TABLE</b>	This mode is the “normal” view of a hash table; as a table of keys and values. When you inspect an item you inspect the value of the item.
-------------------	--

**STRUCTURE** This mode provides a raw view of the whole hash table structure. When you inspect an item you are inspecting the value of that slot in the hash table structure.

**ENUMERATED-HASH-TABLE**

This mode is a variation of the normal view, where a hash table is viewed simply as a list of lists. When you inspect an item you are inspecting a list containing a key and a value.

**HASH-TABLE-STATISTICS**

This mode shows how long the chains in the hash table are, so that you can tell how efficiently it is being used. For example, if all chains contained fewer than two items the hash table would be being used well.

**HASH-TABLE-HISTOGRAM**

This mode shows the statistical information from **HASH-TABLE-STATISTICS** as a histogram.

Here is an example of hash table inspection.

```
CL-USER 1 > (defvar *hash* (make-hash-table))
*HASH*

CL-USER 2 > (setf (gethash 'lisp *hash*) 'programming
                    (gethash 'java *hash*) 'programming
                    (gethash 'c *hash*) 'programming
                    (gethash 'c++ *hash*) 'programming
                    (gethash 'english *hash*) 'natural
                    (gethash 'german *hash*) 'natural)
NATURAL

CL-USER 3 > (inspect *hash*)

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE
C++           PROGRAMMING
JAVA          PROGRAMMING
ENGLISH       NATURAL
C              PROGRAMMING
GERMAN        NATURAL
LISP           PROGRAMMING

CL-USER 4 : Inspect 1 > :m
* 1. HASH-TABLE
  2. STRUCTURE
  3. ENUMERATED-HASH-TABLE
  4. HASH-TABLE-STATISTICS
  5. HASH-TABLE-HISTOGRAM
```

STRUCTURE mode displays the raw representation of the hash table:

```
CL-USER 5 : Inspect 1 > :m 2

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE
KIND                  EQL
SIZE                 37
REHASH-SIZE          2.0
REHASH-THRESHOLD    1.0
THRESHOLD            37
COUNTER              525
NUMBER-ENTRIES       6
TABLE                #(#%((LISP . PROGRAMMING) NIL) NIL NIL
NIL NIL ...)
NO-DESTRUCT-REHASH  NIL
POWER2               NIL
HASH-REM              SYSTEM::DIVIDE-GENERAL
HASH-FN               SYSTEM::EQL-HASHFN
GETHASH-FN            SYSTEM::GETHASH-EQL
PUTHASH-FN            SYSTEM::PUTHASH-EQL
REMHASH-FN            SYSTEM::REMHASH-EQL
GET-TLATTER-FN       SYSTEM::GET-TLATTER-EQL
WEAK-KIND             NIL
USER-STUFF            NIL
MODIFICATION-COUNTER 0
FAST-LOCK-SLOT        0
```

In **ENUMERATED-HASH-TABLE** mode you can recursively inspect keys and values by entering the index. This is especially useful in cases where the key or value is unreadable and so cannot be entered into the REPL:

```
CL-USER 6 : Inspect 1 > :m 3

#<EQL Hash Table{6} 21C15D97> is an Enumerated HASH TABLE
0      (C++ PROGRAMMING)
1      (JAVA PROGRAMMING)
2      (ENGLISH NATURAL)
3      (C PROGRAMMING)
4      (GERMAN NATURAL)
5      (LISP PROGRAMMING)

CL-USER 7 : Inspect 1 > 5

(LISP PROGRAMMING) is a LIST
0      LISP
1      PROGRAMMING

CL-USER 8 : Inspect 2 > :u
```

The **HASH-TABLE-STATISTICS** mode shows that **\*hash\*** has 31 chains, of which 25 are empty and 6 have one entry::

```
CL-USER 9 : Inspect 1 > :m 4

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE (statistical view)
chain of length 0 :          31
chain of length 1 :          6
```

In **HASH-TABLE-HISTOGRAM** mode the same information is represented as a histogram:

```
CL-USER 10 : Inspect 1 > :m 5

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE (histogram view)
chain of length 0 :          "*****"
chain of length 1 :          "*****"

CL-USER 11 : Inspect 1 > :q
#<EQL Hash Table{6} 21C15D97>
```

# 5

---

## The Trace Facility

The trace facility is a debugging aid enabling you to follow the execution of particular functions. At any time there are a set of functions (and macros and methods) which are being monitored in this way. The normal behavior when a call is made to one of these functions is for the function's name, arguments and results to be printed out by the system. More generally you can specify that particular forms should be executed before or after entering a function, or that certain calls to the function should cause it to enter the main debugger. Tracing of a function continues even if the function is redefined.

The standard way of arranging for functions to be traced is to call the macro `trace` with the symbols of the functions (or macros or generic functions) concerned. In addition it is possible to restrict tracing to a particular method (rather than a generic function) as described in “Tracing methods” on page 57. The trace facility also handles recursive and nested calls to the functions concerned.

### 5.1 Simple tracing

This section shows you how to perform simple traces.

1. Enter this definition of the factorial function `fac` into the listener:

```
(defun fac (n)
  (if (= n 1) 1
    (* n (fac (- n 1)))))
```

2. Now trace the function by entering the following into the listener.

```
(trace fac)
```

3. Call the function `fac` as follows:

```
(fac 3)
```

The following trace output appears in the listener.

```
0 FAC > ...
  >> N : 3
1 FAC > ...
  >> N : 2
2 FAC > ...
  >> N : 1
2 FAC < ...
  << VALUE-0 : 1
1 FAC < ...
  << VALUE-0 : 2
0 FAC < ...
  << VALUE-0 : 6
```

Upon entry to each traced function call, `trace` prints the following information:

- The level of tracing, that is, the number of recursive entries to `trace`.
- The traced function name.
- The arguments and their values for the current call.

Each line is indented according to the level of tracing for the call.

`>` denotes entry to a function, and `>>` denotes an argument.

Upon exit from each traced function call, `trace` prints the following information:

- The level of tracing.
- The traced function name.
- The returned values for the current call.

< denotes exit from a function, and << denotes a returned value.

Output produced in this way is always sent to a special stream, **\*trace-output\***, which is either associated with the listener, or with background output.

Calling **trace** with no arguments produces a list of all the functions currently being traced. In order to cease tracing a function the macro **untrace** should be called with the function name. All tracing can be removed by calling **untrace** with no arguments.

```
CL-USER 5 > (untrace fac)
(FAC)

CL-USER 6 > (fac 4)
24

CL-USER 7 >
```

## 5.2 Tracing options

There are a number of options available when using the trace facilities, which allow you both to restrict or expand upon the information printed during a trace. For instance, you can restrict tracing of a function to a particular process, or specify additional actions to be taken on function call entry and exit.

Note that the options and values available only apply to a particular traced function. Each traced function has its own, independent, set of options.

This section describes the options that are available. Each option can be set as described in the next subsection.

### 5.2.1 Evaluating forms on entry to and exit from a traced function

<b>:before</b>	<i>Trace keyword</i>
----------------	----------------------

**:before** *list-of-forms*

If non-nil, the list of forms is evaluated on entry to the function being traced. The forms are evaluated and the results printed after the arguments to the function.

Here is an example of its use. `*traced-arglist*` is bound to the list of arguments given to the function being traced. In this example, it is used to accumulate a list of all the arguments to `fac` across all iterations.

1. In the listener, initialize the variable `args-in-reverse` as follows:

```
(setq args-in-reverse ())
```

2. For the `fac` function used earlier, set the value of `:before` as follows:

```
(trace (fac :before ((push (car *traced-arglist*) args-in-reverse))))
```

3. In the listener, evaluate the following form:

```
(fac 3)
```

After evaluating this form, `args-in-reverse` has the value `(1 2 3)`, that is, it lists the arguments which `fac` was called with, in reverse order.

<code>:after</code>	<i>Trace keyword</i>
---------------------	----------------------

`:after list-of-forms`

If non-nil, this option evaluates a list of forms upon return from the function to be traced. The forms are evaluated and the results printed after the results of a call to the function.

This option is used in exactly the same way as `:before`. For instance, using the example for `:before` as a basis, create a list called `results-in-reverse`, and set the value of `:after` so that `(car *traced-results*)` is pushed onto this list. After calling `fac`, `results-in-reverse` contains the results returned from `fac`, in reverse order.

Note also that `*traced-arglist*` is still bound.

### 5.2.2 Evaluating forms without printing results

<code>:eval-before</code>	<i>Trace keyword</i>
---------------------------	----------------------

`:eval-before list-of-forms`

This option allows you to supply a list of forms for evaluation upon entering the traced function. The forms are evaluated after printing out the arguments to the function, but unlike `:before` their results are not printed.

**:eval-after***Trace keyword*`:eval-after` *list-of-forms*

This option allows you to supply a list of forms for evaluation upon leaving the traced function. The forms are evaluated after printing out the results of the function call, but unlike `:after` their results are not printed.

### 5.2.3 Using the debugger when tracing

**:break***Trace keyword*`:break` *form*

If *form* evaluates to non-nil, the debugger is entered directly from `trace`. If it returns `nil`, tracing continues as normal. This option lets you force entry to the debugger by supplying a *form* as simple as `t`.

Upon entry to the traced function, the standard trace information is printed, any supplied `:before` forms are executed, and then *form* is evaluated.

**:break-on-exit***Trace keyword*`:break-on-exit` *form*

Like `:break`, this option allows you to enter the debugger from `trace`. It differs in that the debugger is entered *after* the function call is complete.

Upon exit from the traced function, the standard trace information is printed, and then *form* is evaluated. Finally, any supplied `:after` forms are executed.

**:backtrace** *Trace keyword*

**:backtrace *backtrace***

Generates a backtrace on each call to the traced function. *backtrace* can be any of the following values:

**:quick** Like the `:bq` debugger command.

**t** Like the `:b` debugger command.

**:verbose** Like the `:b :verbose` debugger command.

**:bug-form** Like the `:bug-form` debugger command.

## 5.2.4 Entering stepping mode

**:step** *Trace keyword*

**:step *form***

When non-nil, this option puts the trace facility into stepper mode, where interpreted code is printed one step of execution at a time.

## 5.2.5 Configuring function entry and exit information

**:entrycond** *Trace keyword*

**:entrycond *form***

This option controls the printing of information on entry to a traced function. *form* is evaluated upon entry to the function, and information is printed if and only if *form* evaluates to `t`. This allows you to turn off printing of function entry information by supplying a *form* of `nil`, as in the example below.

**:exitcond** *Trace keyword*

**:exitcond *form***

This option controls the printing of information on exit from a traced function. *form* is evaluated upon exit from the function, and, like

`:entrycond`, information is printed if and only if *form* evaluates to a non-nil value. This allows you to turn off printing of function exit information by supplying a *form* of `nil`.

An example of using `:exitcond` and `:entrycond` is shown below:

1. For the `fac` function, set the values of `:entrycond` and `:exitcond` as follows.

```
(trace (fac :entrycond (evenp (car *traced-arglist*))
                           :exitcond (oddp (car *traced-arglist*))))
```

Information is only printed on entry to `fac` if the argument passed to `fac` is even. Conversely, information is only printed on exit from `fac` if the argument passed to `fac` is odd.

2. Enter the following call to `<Code>fac</Code>` in a listener:

```
CL-USER 24 > (fac 10)
```

The tracing information printed is as follows:

```
0 FAC > ...
  >> N : 10
2 FAC > ...
  >> N : 8
4 FAC > ...
  >> N : 6
6 FAC > ...
  >> N : 4
8 FAC > ...
  >> N : 2
9 FAC < ...
  << VALUE-0 : 1
7 FAC < ...
  << VALUE-0 : 6
5 FAC < ...
  << VALUE-0 : 120
3 FAC < ...
  << VALUE-0 : 5040
1 FAC < ...
  << VALUE-0 : 362880
```

### 5.2.6 Directing trace output

**:trace-output** *Trace keyword*

**:trace-output *stream***

This option allows you to direct trace output to a stream other than the listener in which the original function call was made. By using this you can arrange to dispatch traced output from different functions to different places.

Consider the following example:

1. In the listener, create a file stream as follows:

```
CL-USER 1 > (setq str (open "trace.txt" :direction :output))
Warning: Setting unbound variable STR
#<STREAM::LATIN-1-FILE-STREAM C:\temp\trace.txt>
```

2. Set the value of the **:trace-output** option for the function **fac** to **str**.
3. Call the **fac** function, and then close the file stream as follows:

```
CL-USER 138 > (fac 8)
40320

CL-USER 139 > (close str)
T
```

Inspect the file **trace.txt** in order to see the trace output for the call of **(fac 8)**.

### 5.2.7 Restricting tracing

**:process** *Trace keyword*

**:process *process***

This lets you restrict tracing of a function to a particular process. If *process* evaluates to **t**, then the function is traced from within all processes (this is the default). Otherwise, the function is only traced from within the process that *process* evaluates to.

**:when***Trace keyword***:when *form***

This lets you invoke the tracing facilities on a traced function selectively. Before each call to the function, *form* is evaluated. If *form* evaluates to `nil`, no tracing is done. The contents of `*traced-arglist*` can be examined by *form* to find the arguments given to `trace`.

## 5.2.8 Storing the memory allocation made during a function call

**:allocation***Trace keyword***:allocation *form***

If *form* is non-`nil`, this prints the memory allocation, in bytes, made during a function call. The symbol that *form* evaluates to is used to accumulate the amount of memory allocated between entering and exiting the traced function.

Note that this symbol continues to be used as an accumulator on subsequent calls to the traced function; the value is compounded, rather than over-written.

Consider the example below:

1. For the `fac` function, set the value of `:allocation` to `$$fac-alloc`.
2. In the listener, call `fac`, and then evaluate `$$fac-alloc`.

```
CL-USER 152 > $$fac-alloc
744
```

## 5.2.9 Tracing functions from inside other functions

**:inside***Trace keyword***:inside *list-of-functions***

The functions given in the argument to `:inside` should reference the traced function in their implementation. The traced function is then only

traced in calls to any function in the list of functions, rather than in direct calls to itself.

For example:

1. Define the function `fac2`, which calls `fac`, as follows:

```
(defun fac2 (x)
  (fac x))
```

2. For the `fac` function, set the value of `:inside` to `fac2`:

```
(trace (fac :inside fac2))
```

3. Call `fac`, and notice that no tracing information is produced.

```
CL-USER 2 > (fac 3)
6
```

4. Call `fac2`, and notice the tracing information.

Evaluate `(fac2 3)`, and notice the tracing information.

```
0 FAC > ...
  >> N : 3
1 FAC > ...
  >> N : 2
2 FAC > ...
  >> N : 1
2 FAC < ...
  << VALUE-0 : 1
1 FAC < ...
  << VALUE-0 : 2
0 FAC < ...
  << VALUE-0 : 6
```

## 5.3 Example

The following example illustrates how `trace` may be used as a debugging tool. Suppose that you have defined a function `f`, and intend its first argument to be a non-negative number. You can trap calls to `f` where this is not true, providing an entry into the main debugger in these cases. It is then possible for you to investigate how the problem arose.

To do this, you specify a `:break` option for `f` using `trace`. If the form following this option evaluates to a non-nil value upon calling the function, then the

debugger is entered. In order to inspect the first argument to the function `f`, you have access to the variable `*traced-arglist*`. This variable is bound to a list of the arguments with which the function was called, so the first member of the list corresponds to the first argument of `f` when tracing `f`.

```
CL-USER 1 > (defun f (a1 a2) (+ (sqrt a1) a2))
F

CL-USER 2 > (trace (f :break (< (car *traced-arglist*) 0)))
(F)

CL-USER 3 > (f 9.0 3)
0 F > ...
  >> A1 : 9.0
  >> A2 : 3
0 F < ...
  << VALUE-0 : 6.0
6.0

CL-USER 4 > (f -16.0 3)
0 F > ...
  >> A1 : -16.0
  >> A2 : 3

Break on entry to F with *TRACED-ARGLIST* (-16.0 3).
1 (continue) Return from break.
2 Continue with trace removed.
3 Continue traced with break removed.
4 Continue and break when this function returns.
5 (abort) Return to level 0.
6 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or :? for
other options.

CL-USER 5 : 1 >
```

## 5.4 Tracing methods

You can also trace methods (primary and auxiliary) within a generic function. The following example shows how to specify any qualifiers and specializers.

1. Type the following methods into the listener:

```
(defmethod foo (x)
  (print 'there))

(defmethod foo :before ((x integer))
  (print 'hello))
```

2. Next, trace only the second of these methods by typing the following definition spec.

```
(trace (method foo :before (integer)))
```

3. Test that the trace has worked by calling the methods in the listener:

```
CL-USER 226 > (foo 'x)
```

```
THERE
THERE
```

```
CL-USER 227 > (foo 4)
0 (METHOD FOO :BEFORE (INTEGER)) > (4)
```

```
HELLO
0 (METHOD FOO :BEFORE (INTEGER)) < (HELLO)
```

```
THERE
THERE
```

```
CL-USER 228 >
```

## 5.5 Tracing subfunctions

Subfunctions are functions that are defined inside the body of other functions rather than by top level definers like `defun`, `defmethod`, etc. To trace such a subfunction, call `trace` with a "subfunction dspec" in one of these forms:

- (`subfunction sub-name parent-dspec`)
- (`flet sub-name parent-dspec`)
- (`labels sub-name parent-dspec`)

See “Subfunction dspecs” on page 85 for details. All of the keywords that `trace` takes have the same effect for subfunction tracing.

The behavior when tracing a subfunction is somewhat different from tracing other function.

- `trace` modifies the parent of the subfunction such that future execution of the code that creates the subfunction will create it traced.
- A subsequent call to `trace` with the same dspec re-modifies the parent, and also causes any of the subfunctions that were already created traced to change their tracing behavior (as defined by the keywords to `trace`) to the behavior specified by the latest call to `trace`.
- `untrace` with the same dspec returns the parent function to its original state and switches off tracing for the subfunctions that were created traced.
- A call to `trace` with the same dspec after `untrace` modifies the parent as in the first point above, but has no effect on any subfunction that was created by the parent before the call to `untrace`.

Tracing of subfunction works only for compiled functions.

### 5.5.1 Notes on subfunction names

Anonymous lambdas are named by the compiler using integers.

You can find the dspec of a given subfunction by calling `object-dspec` on the subfunction. You can also construct it from the printed representation of the subfunction, which contains the sub-name and the parent-dspec.

A subfunction can be given an name using a `hcl:lambda-name` declaration (see `declare`, page 651). If this is of the form `(subfunction sub-name)`, then the dspec of the subfunction will contain both *sub-name* and the correct parent-dspec. However, if it has any other form, then dspec will be that name and you will need to know the parent-dspec in order to construct the subfunction dspec.

## 5.6 Trace variables

**\*max-trace-indent\***

The maximum indentation used during output from `trace`.

**\*trace-indent-width\***

The additional amount by which tracing output is indented upon entering a deeper level of nesting.

**\*trace-level\***

The current depth of tracing.

**cl:\*trace-output\***

The stream to which tracing sends its output by default.

**\*traced-arglist\***

The variable that holds the arguments given to the traced function.

**\*traced-results\***

The variable that holds the results from the traced function.

The following four variables allow you to control the style of tracing output separately from normal printing:

**\*trace-print-circle\***

The value to which **\*print-circle\*** is bound during output from **trace**.

**\*trace-print-length\***

The value to which **\*print-length\*** is bound during output from **trace**.

**\*trace-print-level\***

The value to which **\*print-level\*** is bound during output from **trace**.

**\*trace-print-pretty\***

The value to which **\*print-pretty\*** is bound during output from **trace**.

## 5.7 Troubleshooting tracing

This section describes some of the common problems seen when tracing, with suggestions to overcome these.

### 5.7.1 Excessive output

In general it is not useful to trace `c1:length` and other base-level functions unconditionally because they are called too frequently by LispWorks itself.

It may be useful to trace these functions in a limited fashion, using the `trace` options `:inside` or `:when`.

### 5.7.2 Missing output

There are two common reasons for not seeing calls you expect in trace output.

#### 5.7.2.1 Compiled code may not call the functions you expect

There are many other optimizations built-in to the LispWorks compiler, which affect code generated according to the compiler qualities in effect at compile-time. For example if the compiler was set to inline structure accessors, then tracing structure accessors in code compiled with that setting will produce no output.

While debugging, you could re-compile the code at higher safety or run it interpreted, to obtain the trace output.

#### 5.7.2.2 trace works on function names, not function objects

`trace` works by tracing function names, not function objects.

Therefore tracing function objects, for example by

```
(trace #'foo)
```

will not yield any trace output. Instead you need to do

```
(trace foo)
```

Also, if the symbol `foo` is traced, then code which invokes `foo` by

```
(funcall (symbol-function 'foo) ...)
```

or equivalently

```
(funcall #'foo ...)
```

will not produce any trace output.

The correct approach is to use `(funcall 'foo ...)` instead of `(funcall #'foo ...)`.

# 6

---

## The Advice Facility

The advice facility provides a mechanism for altering the behavior of existing functions. As a simple application of this, you may supplement the original function definition by supplying additional actions to be performed before or after the function is called. Alternatively, you may replace the function with a new piece of code that has access to the original definition, but which is free to ignore it altogether and to process the arguments to the function and return the results from the function in any way you decide. The advice facility allows you to alter the behavior of functions in a very flexible manner, and may be used to engineer anything from a minor addition of a message, to a major modification of the interface to a function, to a complete change in the behavior of a function. This facility can be helpful when debugging, or when experimenting with new versions of functions, or when you wish to locally change some functionality without affecting the original definition.

**Note:** It can be dangerous to put advice on system functions or functions used at low-level by the system. In general, advising a basic Common Lisp function (that is, a simple function for manipulating simple objects such as `reverse`) is dangerous, because the implementation may use it.

## 6.1 Defining advice

Each change that is required should be specified using the `defadvice` macro. This defines a new body of code to be used when the function is called; this piece of code is called a piece of advice. Consider the following example:

```
(defadvice
  (capi:prompt-for-file pff-1 :before)
  (message &key &allow-other-keys)
  (format t "~&Prompting for file with message ~S~%" message))
```

Here `defadvice` is given the name of the function you want to alter, a name for the piece of advice, and the keyword `:before` to indicate that you want the code carried out before `capi:prompt-for-file` is called. The rest of the call to `defadvice` specifies the additional behavior required, and consists of the lambda list for the new piece of advice and its body (the lambda list may specify keyword parameters and so forth). The advice facility arranges that `pff-1` is invoked whenever `capi:prompt-for-file` is called, and that directly after this the original definition of `capi:prompt-for-file` is called.

After executing this advice definition, demonstrate it by selecting the menu command **File > Open** in the LispWorks IDE. The message appears in the **Output** tab.

Pieces of advice may be given to be executed after the call by specifying `:after` instead of `:before` in the call to `defadvice`. So if you wished to add further code to be performed after `capi:prompt-for-file` you could also define:

```
(defadvice
  (capi:prompt-for-file pff-2 :after)
  (message &rest args)
  (format t
    "~&The other arguments to prompt-for-file were: ~S~%" args))
```

Note that `pff-2` also receives the arguments to `capi:prompt-for-file`, which are reported by the body.

Note also that `defadvice` works on function names, not function objects, like `trace`. See “trace works on function names, not function objects” on page 61 for details.

## 6.2 Combining the advice

We have already seen how a before and an after piece of advice may be combined, and this section describes the general algorithm. There are three types of advice: *before*, *after* and *around*. These resemble before, after and around methods in CLOS. There may be several pieces of each type of advice present for a particular function.

The first step in working out how the combination is done is to order the pieces of advice. All the around advice comes first, then all the before advice, then the original definition, and lastly the after advice. The order within each of the around, before and after sections defaults to the order in which the pieces of advice were defined (that is most recent first). See `defadvice`, page 1100 for details of how to control the ordering of advice within each section.

The remainder of this section discusses what happens when a function that has advice is called.

### 6.2.1 :before and :after advice

First we deal with the case when there is no around advice present. Here each of the pieces of before advice are called in turn, with the same arguments that were given to the function, next the original definition is called with these arguments, and finally each of the pieces of after advice is called in reverse order with the same arguments (so that by default the most recently added piece of after advice is invoked last). The results returned by the function call are the values produced by the last piece of after advice to be called (if there is one), or by the original definition (if there is no after advice).

Note that none of these bits of code should destructively modify the arguments that they receive. Adding a piece of before advice thus provides a simple way of specifying some additional action to be performed before the original definition, and before any older bits of before advice. Adding a piece of after advice allows you to specify extra actions to be performed after the original definition, and after any older bits of after advice. The advice facility automatically links together these bits of advice with the original function definition.

### 6.2.2 :around advice

Next we shall discuss the use of around advice, which provides you with greater control than do before and after advice. Let us suppose that a function that has some around advice is called. The arguments to the function are passed to the code associated with the first piece of around advice in the ordering, and the values returned by that piece of advice are the results of the function. There is no requirement for the advice to invoke any other pieces of advice, nor to call the original definition of the function.

However the code for any piece of around advice has access to the next member of the ordering, which it may invoke any number of times by calling `call-next-advice`. So it is possible for each piece of around advice to call its successor in the ordering if this is desired, and then the bits of around advice are called in turn in a similar fashion to our earlier description for before and after advice. However in the case of around advice the decision whether or not to call the next piece of advice is directly under your control, and you are free to modify the arguments received by the piece of advice, and to choose the arguments to be given to the next piece of advice if it is called.

If the last piece of around advice in the ordering calls `call-next-advice`, then it invokes the combination of before and after advice and the original definition that was discussed earlier. That is, the arguments to the call are given in the sequence described above to each of the before pieces of advice, then to the original definition and then to the after pieces of advice. The call to `call-next-advice` returns with the values produced by the last of these subsidiary calls, and the around advice may use these values in any way.

## 6.3 Removing advice

The macro `delete-advice` (or the function `remove-advice`) may be used to remove a named piece of advice. Since several pieces of advice may be attached to a single functional definition, the name must be supplied to indicate which one is to be removed.

```
CL-USER 40 > (delete-advice capi:prompt-for-file pff-1)
NIL
```

```
CL-USER 41 > (delete-advice capi:prompt-for-file pff-2)
NIL
```

## 6.4 Advice for macros and methods

As well as attaching advice to ordinary functions, it may also be attached to macros and methods.

In the case of a macro, advice is linked to the macro's expansion function, and so any before or after advice receives a copy of the arguments given to this expansion function (normally the macro call form and an environment). A simple example:

```
CL-USER 45 > (defmacro twice (b) `(+ ,b ,b))
TWICE

CL-USER 46 > (defadvice
  (twice before-twice :before)
  (call-form env)
  (format t
    "~~%Twice with environment ~A and call-form ~A"
    env call-form))
NIL

CL-USER 47 > (twice 3)
Twice with environment NIL and call-form (TWICE 3)
6
```

Note that the advice is invoked when the macro's expansion function is used. So if the macro is present within a function that is being compiled, then the advice is invoked during compilation of that function (and not when that function is finally used).

In the case of a method, the call to `defadvice` must also specify precisely to which method the advice belongs. A generic function may have several methods, so the call to `defadvice` includes a list of classes. This must correspond exactly to the parameter specializers of one of the methods for that generic function, and it is to that method that the advice is attached. For example:

```

CL-USER 45 > (progn
  (defclass animal ()
    (genus habitat description
      (food-type :accessor eats)
      (happiness :accessor how-happy)
      (eaten :accessor eaten :initform nil)))
  (defclass cat (animal)
    ((food-type :initform 'fish)))
  (defclass elephant (animal)
    (memory (food-type :initform 'hay)))
  (defmethod feed ((animal animal))
    (let ((food (eats animal)))
      (push food (eaten animal))
      (format t "~%Feeding ~A with ~A" animal
        food)))
  (defmethod feed ((animal cat))
    (let ((food (eats animal)))
      (push food (eaten animal))
      (push 'milk (eaten animal))
      (format t "~%Feeding cat ~A with ~A and ~A"
        animal food 'milk)))
  (defvar *cat* (make-instance 'cat))
  (defvar *nellie* (make-instance 'elephant)))
*PELLIE*

CL-USER 46 > (feed *cat*)
Feeding cat #<CAT 6f35d4> with FISH and MILK
NIL

CL-USER 47 > (feed *nellie*)
Feeding #<ELEPHANT 71e7bc> with HAY
NIL

CL-USER 48 > (defadvice
  ((method feed (animal))
   after-feed :after)
  (animal)
  (format t "~%-A has eaten ~A"
    animal (eaten animal)))
NIL
CL-USER 49 > (defadvice
  ((method feed (cat))
   before-feed :before)
  (animal)
  (format t "~%Stroking ~A" animal)
  (setf (how-happy animal) 'high))
NIL

```

```

CL-USER 50 > (feed *cat*)
Stroking #<CAT 6f35d4>
Feeding cat #<CAT 6f35d4> with FISH and MILK
NIL

CL-USER 51 > (feed *nellie*)
Feeding #<ELEPHANT 71eb7c> with HAY
#<ELEPHANT 71eb7c> has eaten (HAY HAY)

```

## 6.5 Advising subfunctions

Subfunctions are functions that are defined inside the body of other functions rather than by top level defining forms like `defun`, `defmethod`, etc. To advise such a subfunction, call `defadvice` with a "subfunction dspec" of the form:

- `(subfunction sub-name parent-dspec)`
- `(flet sub-name parent-dspec)`
- `(labels sub-name parent-dspec)`

See “Subfunction dspecs” on page 85 for details. The rest of the `defadvice` form has the same effect as when advising ordinary functions.

The behavior when advising a subfunction is somewhat different from advising other functions.

- `defadvice` modifies the parent of the subfunction such that future execution of the code that creates the subfunction will create it advised.
- A subsequent call to `defadvice` with the same dspec and name re-modifies the parent, and also causes any of the subfunctions that were already created advised to change their "advice" behavior (as defined by the `defadvice` form) to the behavior specified by the latest call to `defadvice`.
- `remove-advice` with the same dspec and name returns the parent function to its original state, and switches off the "advice" for the subfunctions that were created "advised".
- Using `defadvice` again with the same dspec and name after `remove-advice` modifies the parent as in the first point above, but has no affect

on any subfunction that was created by the parent before the call to `remove-advice`.

Advising of subfunction works only for compiled code.

### 6.5.1 Notes on subfunction names

Anonymous lambdas are named by the compiler using integers.

You can find the dspec of a given subfunction by calling `object-dspec` on the subfunction. You can also construct it from the printed representation of the subfunction, which contains the sub-name and the parent-dspec.

A subfunction can be given an name using a `hcl:lambda-name` declaration (see `declare`, page 651). If this is of the form `(subfunction sub-name)`, then the dspec of the subfunction will contain both *sub-name* and the correct parent-dspec. However, if it has any other form, then dspec will be that name and you will need to know the parent-dspec in order to construct the subfunction dspec.

## 6.6 Examples

So far you have only seen examples of before and after pieces of advice. This section contains some further examples. Suppose that you define a function `alpha` that squares a number, and then decide that you intended to return the reciprocal of the square instead. You might proceed as follows.

```
CL-USER 30 > (defun alpha (x) (* x x))
ALPHA

CL-USER 31 > (defadvice
                 (alpha reciprocal :around)
                 (num)
                 (/ (call-next-advice num)))
NIL

CL-USER 32 > (alpha -5)
1/25
```

First you change `alpha` to return the reciprocal of the square. Do this by defining an around method to take the reciprocal of the result produced by the next piece of advice (which initially is the original definition). Now suppose that

you later decide that you would like `alpha` to return the sum of the squares of the reciprocals in a certain range. You can achieve this by adding an extra layer of around advice. This must iterate over the range required, summing the results obtained by the calls to the next piece of advice (which currently yields the reciprocal of the square of its argument).

```
CL-USER 36 > (defadvice
  (alpha sum-over-range :around)
  (start end)
  (loop for i from start upto end
        summing (call-next-advice i)))
NIL

CL-USER 37 > (alpha 2 5)
1669/3600
```

Note that `alpha` now behaves as a function requiring two arguments; the outer piece of around advice determines the external interface to the function, and uses the inner pieces of advice as it needs - in this case invoking the inner advice a variable number of times depending on the range specified. The use of the words “outer” and “inner” corresponds to earlier and later pieces of around advice in the ordering discussed above, but is more descriptive of their behavior.

You now realize that taking the reciprocal of zero gives an error. You decide that you wish to generate an error if `alpha` is called in such a way as to cause this, but that you want to generate the error yourself. You also decide to add a warning message for negative arguments. As you want these actions to be performed as the last (that is innermost) in the chain of around advice, you specify this in the call to `defadvice` by giving it a `:where` keyword with value `:end`.

```

CL-USER 41 > (defadvice
                  (alpha zero-or-negative
                      :around :where :end)
                  (x)
                  (unless (plusp x)
                      (format t
                          "~%**Warning: alpha is being called with ~A"
                          x))
                  (if (zerop x)
                      (error "Alpha cannot be called with zero")
                      (call-next-advice x)))
NIL

CL-USER 42 > (alpha -5 -2)

**Warning: alpha is being called with -5
**Warning: alpha is being called with -4
**Warning: alpha is being called with -3
**Warning: alpha is being called with -2
1669/3600

CL-USER 43 > (alpha 0 3)

**Warning: alpha is being called with 0
Error: alpha cannot be called with zero
 1 (abort) return to level 0.
 2 return to top loop level 0

Type :c followed by a number to proceed

CL-USER 44 : 1 > :a

```

Finally you decide to alter `alpha` yet again, this time to produce approximations to  $\pi$ .  $\pi^2/6$  is the sum of the reciprocals of the squares of all the positive integers. So you can generate an approximation to  $\pi$  using the sum of the reciprocals of the squares of the integers from one to some limit. (In fact this is not an efficient way of calculating  $\pi$ , but it could be of interest.)

```

CL-USER 51 > (defadvice
                  (alpha pi-approximation :around)
                  (limit)
                  (sqrt
                      (* 6
                          (call-next-advice 1.0 limit))))
NIL

```

Next, try calling the following in turn:

```
(alpha 10.0)
(alpha 100.0)
(alpha 1000.0)
pi
```

Lastly, here is a simple example showing a use of advice with an `&rest` lambda list:

```
(defun foo (a b c)
  (print (list a b c)))

(defadvice (foo and-rest-advice :around) (&rest args)
  (format t "advice called with args ~S" args)
  (apply #'call-next-advice args))
```

## 6.7 Advice functions and macros

The main functions used for advice are introduced below. See the reference pages for full details.

The main macro used to define new pieces of advice is `defadvice`

Pieces of around advice should use `call-next-advice` to invoke the next piece of advice. As explained earlier this either calls the next piece of around advice (if one exists), or calls the combination of before advice, the original definition, and after advice. It may only be called from within the body of the around advice.

To remove a piece of advice, use the macro `delete-advice` or the function `remove-advice`.

# Dspecs: Tools for Handling Definitions

The dspec system is the machinery underlying the way definitions are named in LispWorks. It supports program development by tracking the locations of definitions, and is also used in tracing and advising functions.

Dspecs are not expected to work in runtimes delivered at a delivery level greater than 0.

This chapter explains the concepts underlying dspecs and their use in tracking locations of definitions. For full details of the programming interface, see Chapter 36, “The DSPEC Package”.

## 7.1 Dspecs

Definition specifications, or *dspecs*, are a systematic way of naming definitions. The dspec system includes all kinds of definitions provided in LispWorks, and can be extended to include definers that you add.

Most named definitions are global, but local functions can have names, and some of the operations described here can be applied to them as well.

Here are three examples of dspecs:

```
car  
(setf car)
```

```
(defclass standard-object)
```

A dspec is simply a name: you can operate on it even if the thing named does not currently exist.

## 7.2 Forms of dspecs

A dspec is one of:

- A symbol
- A `setf` function name
- A list starting with a symbol naming the class of definition (`method` or `defstruct` for example).

A symbol which is used as a dspec always names a function or a macro.

`(setf foo)` is a name for a `setf` function.

**Note:** `nil` is not a legal dspec, because it cannot have a function definition. Therefore when a dspec API returns `nil`, this should be interpreted in the usual way as "not found" or "not applicable".

### 7.2.1 Canonical dspecs

Internally, dspecs are handled in the canonical form:

```
(dspec-class primary-name . qualifiers)
```

where *dspec-class* is the canonical name of the class, and *qualifiers* is a proper list. *primary-name* is typically a symbol, but can be a list (in the case of a `setf` function) or a string (in the case of a package). The equality for canonical dspecs is `equal`.

As an example the general form of a `defmethod` dspec is:

```
(defmethod name qualifiers (specializer*))
```

<b>name</b>	<b>:</b>	<b>=</b>	<b>symbol</b>	<b> </b>	<b>(setf symbol)</b>
<b>qualifiers</b>	<b>:</b>	<b>=</b>	<b>qualifier</b>	<b> </b>	<b>(qualifier qualifier*)</b>
<b>qualifier</b>	<b>:</b>	<b>=</b>	<b>symbol</b>		
<b>specializer</b>	<b>:</b>	<b>=</b>	<b>symbol</b>	<b> </b>	<b>(eql object)</b>

Functions in the dspec API accept non-canonical dspecs. All dspec functions, except `dspec:prettify-dspec`, `find-dspec-locations`, `name-definition-locations`, `dspec-definition-locations` and `find-name-locations` return canonical dspecs.

## 7.3 Dspec namespaces

Dspec classes are the namespaces for dspecs. Class names are often the same as the name of the defining form, though documentation types as defined for `documentation` are also used. See “Details of built-in dspec classes and aliases” on page 82 for a list of the classes.

### 7.3.1 Dspec classes

Dspec classes provide a set of handlers, to allow uniform handling of different types of definitions by other parts of the system, such as the editor and various browsers.

The most important handlers are `dspec-defined-p` and `dspec-undefiner` for testing if a dspec is currently defined and for undefining a dspec.

New dspec classes are defined using `define-dspec-class`.

Dspec classes can be subclassed. The top-level classes correspond to distinct global namespaces (such as `variable` for variables and constants and `function` for functions and macros), and at each level, all the subclasses are distinct from each other (but they do not have to form a complete partition of the superclass). See “Details of built-in dspec classes and aliases” on page 82 for the full hierarchy of system-provided classes.

You are allowed to define new top-level classes and subclass them, but you cannot add new subclasses to a system-provided class. However, see “Dspec aliases” on page 80 for how to add new ways of making existing definitions.

#### 7.3.1.1 Complete example of a top-level dspec class

Define a `saved-value` object which has a name and a value:

```
(defstruct saved-value
  name
  value)
```

The objects are defined using `def-saved-value` and stored on the plist of their name:

```
(defmacro def-saved-value (name value)
  `(dspec:def (def-saved-value ,name)
    (when (record-definition `(def-saved-value ',name)
                               (dspec:location))
      (setf (get ',name 'saved-value)
            (make-saved-value :name ',name
                              :value ,value)))
    ',name)))
```

Define a function to retrieve the `saved-value` object:

```
(defun find-saved-value (name)
  (get name 'saved-value))
```

Define a macro to access a `saved-value` object:

```
(defmacro saved-value (name)
  `(saved-value-value (find-saved-value ',name)))
```

Define a dspec class for `def-saved-value` dspecs:

```
(dspec:define-dspec-class def-saved-value nil
  "Defined saved values"
  :definedp
  #'(lambda (name)
      ;; Find any object that def-saved-value recorded
      (not (null (find-saved-value name))))
  :undefinedp
  #'(lambda (dspec)
      ;; Remove what def-saved-value recorded
      `(remprop ,(dspec:dspec-name dspec) 'saved-value))
  :object-dspec
  #'(lambda (obj)
      ;; Given a saved-value object, we can reconstruct its dspec
      (and (saved-value-p obj)
           `(def-saved-value ,(saved-value-name obj)))))
```

For completeness, define a form parser that generates dspecs from forms:

```
(dspec:define-form-parser
  (def-saved-value
    (:parser dspec:single-form-form-parser)))
```

**Note:** this form parser for `def-saved-value` is not strictly necessary, because the system provides an implicit form parser which recognizes definitions beginning with "def".

### 7.3.1.2 Example of subclassing

This example is based on that in “Complete example of a top-level dspec class” on page 77.

Define a `computed-saved-value` object has a function to compute the value the first time:

```
(defstruct (computed-saved-value (:include saved-value))
  function)
```

`saved-value` objects are defined using `def-computed-saved-value` and stored on the plist of their name:

```
(defmacro def-computed-saved-value (name function)
  `(dspec:def (def-computed-saved-value ,name)
    (when (record-definition `,(def-computed-saved-value ',name)
      ,(dspec:location))
      (setf (get ',name 'saved-value)
        (make-computed-saved-value :name ',name
          :function ,function)))
    ',name)))
```

Define a function to compute a `computed-saved-value`:

```
(defun ensure-saved-value-computed (name)
  (let ((saved-value (find-saved-value name)))
    (or (saved-value-value saved-value)
        (setf (saved-value-value saved-value)
          (funcall
            (computed-saved-value-function saved-value))))))
```

Define a macro to access a `computed-saved-value`:

```
(defmacro computed-saved-value (name)
  `(ensure-saved-value-computed ',name))
```

Define a dspec class for `def-computed-saved-value` dspecs:

```
(dspec:define-dspec-class def-computed-saved-value def-saved-
value
  "Defined computed saved values"
  :definedp
  #'(lambda (name)
      ;; Find any object that def-computed-saved-value recorded
      (computed-saved-value-p (find-saved-value name)))
  ;; The :undefiner is inherited from the superspace.
  :object-dspec
  #'(lambda (obj)
      ;; Given a computed-saved-value object, we can reconstruct
      its dspec
      (and (computed-saved-value-p obj)
           `(def-computed-saved-value ,(saved-value-name obj)))))
```

For completeness, define a form parser that generates dspecs from forms:

```
(dspec:define-form-parser
  (def-computed-saved-value
    (:parser dspec:single-form-form-parser)))
```

**Note:** this form parser for `def-computed-saved-value` is not strictly necessary, because the implicit form parser will recognize definitions beginning with "def".

### 7.3.2 Dspec aliases

You can add new ways of making existing definitions and use the dspec system to track these definitions. This is what happens when your defining form expands into a system-provided form. The macro `define-dspec-alias` is used to inform the dspec system of this.

For example if your definer is:

```
(defmacro my-defun ((name &rest args) &body body)
  `(defun ,name ,args ,@body))
```

then you would define the form of dspecs for `my-defun` definitions like this:

```
(dspec:define-dspec-alias my-defun (name)
  `(defun ,name))
```

**Note:** in general you should not include the lambda list in the dspec, because it is not needed to locate the definition later.

**Note:** to make source location work you will also need a `define-form-parser` definition for `my-defun`. This is illustrated in “Using pre-defined form parsers” on page 91.

## 7.4 Types of relations between definitions

### 7.4.1 Functionally equivalent definers

When one definition form simply macroexpands into another, or otherwise has an identical effect as far as the dspec system is concerned, the dspec system should consider them variant forms of the same class.

Use `define-dspec-alias` to convert one definer to the other during canonicalization. A pre-defined example of this in LispWorks is `defparameter` and `defvar`. These cannot be distinguished (other than in the source code), so `defparameter` has been defined as a dspec alias for `defvar`. However, `defvar` and `defconstant` are distinct kinds of variable, since we can easily tell which type of definition is in effect by calling the function `constantp`. To define their dspecs, LispWorks creates a dspec class called `variable` and uses it as the superspace argument when defining the `defvar` and `defconstant` dspec classes.

As an explicit example, suppose you have a defining macro

```
(defmacro parameterdef (value name)
  `(defparameter ,name ,value))
```

then

```
(dspec:define-dspec-alias parameterdef (value name)
  `(defparameter ,name))
```

would be a suitable appropriate alias definition. This `define-dspec-alias` form defines the dspec.

`define-dspec-alias` is like `defmacro` for dspecs, so it could be used to describe complicated conversions, as long as it can be done purely statically and totally in terms of existing dspecs. However, nothing more complicated than `defparameter` has been found necessary.

### 7.4.2 Grouping subdefinitions together

Some definition forms are macros that expand into a group of other definitions, for example `defstruct`. When the form is associated with a dspec class, the subdefinitions can be automatically recorded as being subforms of the new definition, by use of the `def` macro.

This means that the dspec system knows that the subdefinitions were inside the main definition (indeed, inside this particular form). Therefore

- Location queries can retrieve this information.
- The source location commands in the LispWorks IDE, when passed a subdefinition, know to search for the main definition given in the `def`.

**Note:** to make source location work you will also need a `define-form-parser` definition for the macro that expands into the `def`.

**Note:** `def` defines a relation between two particular definitions, for example `(defstruct foo)` and `(defun make-foo)`, not between the two dspec classes.

### 7.4.3 Distributed definitions

Some definitions are additions to another class of definition, for example methods are additions to generic functions. We call these *distributed definitions*, consisting of "parts" and "the aggregate".

The primary name of a part gives the primary name of the aggregate it is a part of, and the qualifiers distinguish it from the other parts of the same aggregate. Only a part dspec may have qualifiers.

## 7.5 Details of built-in dspec classes and aliases

This section shows the dspec classes, subclasses and aliases provided by Lisp-Works. Subclasses are indented. Following the list of dspec classes are notes about some of these classes.

The system-defined dspec classes are:

```

COMPILER-MACRO (alias DEFINE-COMPILER-MACRO)
EDITOR:DEFCOMMAND (alias EDITOR:DEFINE-COMMAND-SYNONYM)
DEFINE-ACTION
DEFINE-ACTION-LIST
WIN32:DEFINE-DDE-CLIENT
WIN32:DEFINE-DDE-DISPATCH-TOPIC
DSPEC:DEFINE-DSPEC-CLASS (aliases DSPEC:DEFINE-SUBCLASS-DSPEC-CLASS,
DSPEC:DEFINE-FUNCTION-DSPEC-CLASS)
DSPEC:DEFINE-DSPEC-ALIAS
EDITOR:DEFINE-EDITOR-VARIABLE (alias EDITOR:DEFINE-EDITOR-MODE-VARIABLE)
FLI:DEFINE-FOREIGN-CALLABLE
FLI:DEFINE-FOREIGN-TYPE (alias FLI:DEFINE-FOREIGN-CONVERTER)
DSPEC:DEFINE-FORM-PARSER
CAPI:DEFINE-MENU
DEFSETF (aliases DEFINE-SETF-EXPANDER, DEFINE-SETF-METHOD)
DEFSYSTEM
FUNCTION
  DEFGENERIC
  DEFMACRO (alias DEFINE-MODIFY-MACRO)
  DEFUN (alias SYSTEM:DEFUN-AND-INLINE)
    FLI:DEFINE-FOREIGN-VARIABLE
    FLI:DEFINE-FOREIGN-FUNCTION (alias FLI:DEFINE-FOREIGN-FUNCALLABLE)
  METHOD (alias DEFMETHOD)
  METHOD-COMBINATION (alias DEFINE-METHOD-COMBINATION)
  PACKAGE (alias DEFPACKAGE)
  STRUCTURE (alias DEFSTRUCT)
TYPE
  DEFCLASS
    CAPI:DEFINE-INTERFACE
    CAPI:DEFINE-LAYOUT
    DEFINE-CONDITION
    STRUCTURE-CLASS
  DEFTYPE
VARIABLE
  DEFINE-SYMBOL-MACRO
  DEFCONSTANT
  DEFVAR (aliases DEFGLOBAL-PARAMETER, DEFGLOBAL-VARIABLE,
  DEFPARAMETER)

```

Further dspec classes are defined by modules such as `com` (on Microsoft Windows), `kw` and `sql`.

The canonical form of a symbol dspec is (`function symbol`) and the canonical form of a setf function name dspec is (`function (setf symbol)`).

### 7.5.1 Function dspecs

A function-dspec is a dspec that names a specific function. You can use a function-dspec when you need to specify a function by name, for example in `trace`, `defadvice`, and `set-up-profiler`.

A function-dspec can be either a symbol, a list of the form `(setf symbol)`, or any dspec with a class that is a "function" class, that is `function` or any of the classes listed above under `function`. It can also be a method dspec as described in "CLOS dspec classes" on page 84 or a subfunction dspec as described in "Subfunction dspecs" on page 85.

### 7.5.2 CLOS dspec classes

`defgeneric` and `method` can handle `standard-generic-function` and `standard-method`.

The canonical form of a `defgeneric` dspec is `(defgeneric generic-function-name)`.

The canonical dspec of a `method` is:

```
(method function-name [method-qualifier] (parameter-specializer-name*))
```

Where *function-name*, *method-qualifier* and *parameter-specializer-name* match the ones in the `defmethod` form.

Each *parameter-specializer-name* must match the corresponding specializer for all the required parameters of the method. If a parameter is not specialized in the `defmethod` form then its *parameter-specializer-name* needs to be given as `t`.

For example, a method that is defined by:

```
(defmethod a-method ((arg1 cons) arg2 &optional arg3) ...)
```

has a dspec:

```
(method a-method (cons t))
```

and a method defined like this:

```
(defmethod initialize-instance :after ((a my-class)
                                         &key key1 key2)
  ...)
```

has a dspec:

```
(method initialize-instance :after (my-class))
```

### 7.5.3 Part Classes

`method` is a part class for `defgeneric`.

`compiler-macro` is a part class for `function`.

### 7.5.4 Foreign callable dspecs

For `fli:define-foreign-callable` the canonical name is the foreign name, with any machine-specific prefixes omitted.

## 7.6 Subfunction dspecs

For some purposes, most usefully `trace` and `defadvice`, LispWorks allows dspecs that do not name a global definition, but a local function. These are of the form:

```
(subfunction sub-name parent-dspec)
```

where *parent-dspec* is another dspec (possibly a subfunction dspec itself). For `flet` and `labels`, it is also possible to use the form:

```
(flet sub-name parent-dspec)
```

An alias for `(subfunction (flet sub-name) parent-dspec)`.

or:

```
(labels sub-name parent-dspec)
```

An alias for `(subfunction (labels sub-name) parent-dspec)`.

*sub-name* is the name of the subfunction inside the parent, which by default is determined as follows:

- For subfunctions defined by `flet` and `labels`, the name is a two element list of the form `(flet function-name)` or `(labels function-name)`,

where *function-name* is the function name in the `flet/labels` definition.

- For anonymous lambdas, the compiler names the subfunctions within each parent function by small, increasing integers starting from 1.

You can override the default name by using the LispWorks-specific `hcl:lambda-name` declaration (see `declare`). Note that you should use the form

```
(declare (lambda-name (subfunction sub-name))
```

to get a name that is useful for debugging. If you do not use `subfunction`, then the debugger cannot find the source for function.

Notes:

- The *sub-name* of the subfunction is not used by the dspec system to search its databases, so can be anything.
- Source level debugging does not use the *sub-name* of the subfunction, but does need to be able to find the definition of *parent-dspec*.
- `trace` and `defadvice` search for the function by comparing (using `equal`) the subfunction name in the dspec to the name of each subfunction in the parent function.
- A subfunction dspec can be canonicalized and prettified or passed as an argument to `dspec-definition-locations` (which will find where parent is defined).
- Additionally, pseudo-dspecs like this are allowed for top-level forms:

```
(top-level-form (location tlf))
```

*location* is an atomic location (not containing `:inside`) and *tlf* identifies the top-level form within that location. These are used as parent dspecs in subfunction dspecs and `:inside` locations. These dspecs can be canonicalized and prettified, and can be returned as dspecs from the location finders.

## 7.7 Tracking definitions

The dspec system is used to keep track of global definitions in many ways, and global definition macros usually tell the dspec system when the definition changes.

The main purpose of the system is to keep track of where the definition was located, but it also allows fine-tuned control of redefinitions.

### 7.7.1 Locations

Locations are mainly something the dspec system just stores and retrieves. :inside locations are used to describe definitions located as subforms of other definitions.

:inside locations are usually not explicitly specified, but arise as a result of having two nested definitions, both of which use the `def` and `location` macros to handle the name and location info.

The types of locations and their meanings are:

A pathname      A definition existed in the file named or an editor buffer with that name.

The keyword :listener

A definition was executed interactively in the listener or an editor buffer not associated with a file.

The keyword :unknown

A definition was found in the image (these are entered when a location query does not find any information already in the database).

The keyword :implicit

A definition for a part was recorded, but no information exists for the aggregate.

### 7.7.2 Recording definitions and redefinition checking

The location information is entered into the database when the definition is executed, by the defining function calling `record-definition`.

`record-definition` performs various checks, and returns true or false depending on whether the definition was allowed or not. In particular, it checks whether the same name has already been defined in a different location and if so a warning or error can be signaled. See `record-definition`, page 817 for details.

### 7.7.2.1 Use of record-definition

You should not usually call `record-definition`, since all the system-provided definers call it.

However, for new classes of definition which you add with `define-dspec-class`, you should call `record-definition` for dspecs in their new classes, as shown in “Complete example of a top-level dspec class” on page 77.

### 7.7.2.2 Protecting packages

LispWorks has a mechanism for protecting packages against defining any of their external symbols. By default, all the LispWorks implementation packages are protected. This is configurable by the variables `*packages-for-warn-on-redefinition*` and `*handle-warn-on-redefinition*`.

The protection is useful because it is relatively easy to redefine an external symbol by mistake, and it leads to undefined behavior which is difficult to debug. However, in some circumstances you may want to force such definition. In this case, you can rebind either of `*packages-for-warn-on-redefinition*` or `*handle-warn-on-redefinition*` around the definition to avoid the error.

You can also protect your packages by adding their names to the global value of `*packages-for-warn-on-redefinition*`.

### 7.7.3 Source level debugging and stepping

With suitable compilation options (see `toggle-source-debugging`), the LispWorks debugger will automatically identify the exact subform in the source code for each stack frame. In addition, the Stepper tool in the LispWorks IDE can step subforms in the source code.

This also works for a subform that occurs within a macro expansion, provided that the subform is `eq` to the original subform in the call to the macro. In the rare case where a macro copied a subform, making it non-`eq`, you can use the `replacement-source-form` macro to indicate which original subform should be identified as the source code for the new form.

## 7.8 Finding locations

There are two ways of retrieving location information for definitions in the running LispWorks image:

- query for a `dspec` using `dspec-definition-locations`, or
- query for a *name* in a given set of namespaces using `name-definition-locations`

The difference is that name queries will find the locations of all the part definitions as well as the definition named, whereas `dspec` queries will only find the locations for the definition named (there might be many if it has been redefined).

To provide for sub-definitions hidden in another definition, such as `defstruct` accessors, all location queries produce a list of pairs of `dspecs` and locations, each pair naming a definition within the corresponding location that contains the definition looked for. So a query for an accessor called `foobar` might produce the pair:

```
((defstruct foo) #P"/usr/users/hacker/hacks/hack.lisp")
```

## 7.9 Users of location information

To find location information for definitions made in the running image or recorded in a tags database or a tags file:

- query for a `dspec` using `find-dspec-locations`, or
- query for a *name* in a given set of namespaces using `find-name-locations`

The extent of the search is controlled by the value of the variable `*active-finders*`.

For example, to obtain the locations of the definitions of `foo` across all dspec namespaces, call

```
(dspec:find-name-locations dspec:*dspec-classes* 'foo)
```

Another example of the use of `find-name-locations` is the LispWorks Editor tool's Find Definitions tab.

### 7.9.1 Finding definitions in the LispWorks editor

Returning to our example `parameterdef` definer

```
(defmacro parameterdef (value name)
  `(defparameter ,name ,value))
```

1. Load a file `foo.lisp` containing

```
(parameterdef 42 *foo*)
```

2. Now use **Expression > Find Source** on the symbol `*foo*`. Notice that LispWorks knows which file the definition is in, but cannot find the defining top level form.
3. Also notice that the Definitions tab of the Editor tool does not display the definition of `*foo*`. This is because the Editor does not recognize `parameterdef` as a definer. When the LispWorks editor looks at the definitions in a buffer, it needs to know the dspecs that each defining form will generate when evaluated. You can tell the editor how to parse a defining form to generate the dspec by using `define-form-parser`.
4. Now evaluate these forms to associate a parser with `parameterdef` and inform the dspec system that `parameterdef` is another way of naming a `defparameter` dspec:

```
(dspec:define-form-parser parameterdef (value name)
  `(parameterdef ,name))
```

```
(dspec:define-dspec-alias parameterdef (name)
  `(defparameter ,name))
```

5. Now use **Expression > Find Source** on the symbol `*foo*` again. Notice that the source of the definition of `*foo*` is displayed correctly in the text tab of the Editor tool, and that the Definitions tab displays the definition as

```
(parameterdef *foo*)
```

### 7.9.2 Using pre-defined form parsers

LispWorks provides form parsers `name-only-form-parser`, `single-form-form-parser` and `single-form-with-options-form-parser`. You can use `single-form-with-options-form-parser` as the parser for `my-defun` definitions (see “Dspec aliases” on page 80), like this:

```
(dspec:define-form-parser (my-defun
                           (:parser dspec:single-form-with-options-form-parser)))
```

This allows the Editor to locate definitions like:

```
(my-defun (foo x y)
          (+ x y))
```

You can identify the form parser defined for a dspec class using `get-form-parser`.

### 7.9.3 The editor’s implicit form parser

When testing your form parsers bear in mind that the LispWorks editor has an implicit form parser, independent of explicit parsers defined in the dspec system. It tries to parse a dspec from a top level form which is of length 2 or more and whose car has symbol name beginning with "DEF". That is:

```
(defxyz name forms)
```

gets parsed as

```
(defxyz name)
```

which may be a dspec (and thus provides a match for the source location commands). This mechanism operates only when there's no explicit parser defined for `defxyz`.

The editor’s implicit form parser is useful because it matches a common simple case. However it does not work for the `parameterdef` example, because that definer’s symbol name does not begin with "DEF".

### 7.9.4 Reusing form parsers

The form parser established above was specifically for `parameterdef` forms. However if you have other definers of similar syntax - in this example, definers for which the name is the second subform - then you can define a form parser which can be associated with each of them, as follows:

```
(dspec:define-form-parser (name-second (:anonymous t))
                           (value name)
                           `,(name-second ,name))
```

Note that the `name-second` variable is evaluated in the body of the parser. Supposing you have another defining macro `constantdef`:

```
(defmacro constantdef (value name)
                      `(defconstant ,name ,value))
```

then you can associate the same parser with both this and `parameterdef`:

```
(dspec:define-form-parser (parameterdef
                           (:parser name-second-form-parser)))

(dspec:define-form-parser (constantdef
                           (:parser name-second-form-parser)))
```

### 7.9.5 Example: defcondition

Suppose you have a macro based on `define-condition`:

```
(defmacro defcondition (&rest args)
                      `(define-condition ,@args))
```

When the following form is evaluated, the system records the dspec (`define-condition foo`):

```
(defcondition foo () ())
```

Two setups are needed to allow the editor to locate such a defining form.

Firstly, this tells the system how to parse (`defcondition ...`) toplevel forms:

```
(dspec:define-form-parser
  (defcondition
    (:alias define-condition)))
```

So now:

```
(dspec:parse-form-dspec '(defcondition foo () ()))
=>
(defcondition foo)
```

Secondly, this tells the system that (defcondition foo) is an alias for (define-condition foo).

With this, the editor would report "Cannot find (DEFINE-CONDITION FOO) in ...".

```
(dspec:define-dspec-alias defcondition (name)
  `(define-condition ,name))
```

So now this definition can be located:

```
(defcondition foo () ())
```

just as if it were:

```
(define-condition foo () ())
```

### 7.9.6 Example: my-defmethod

Suppose you have a method definer `my-defmethod`:

```
(defmacro my-defmethod ((name &key doc)
  lambda-list
  &body body)
  `(defmethod ,name ,lambda-list ,@body))
```

Unlike function dspecs, method dspecs need to include the specialized argument types as well as the function name, so the alias and the parser both need to be more complex.

This causes the dspec to include the argument types:

```
(dspec:define-dspec-alias my-defmethod (name &rest options)
  `(defmethod ,name ,@options))
```

The dspec parser for method lambda lists is complicated, but you can invoke the `defmethod` parser in your `my-defmethod` parser, like this:

```
(dspec:define-form-parser my-defmethod (name-stuff lambda-list)
  `(.my-defmethod ,(cdr (dspec:parse-form-dspec
    `(defmethod ,(car name-stuff)
      ,lambda-list))))
```

Now this definition can be located:

```
(my-defmethod (bar :doc "bar documentation") (x y)
  (foo x y))
```

just as if it were:

```
(defmethod bar (x y)
  (foo x y))
```

## Action Lists

Action-lists are a unified approach to various different mechanisms for running initializations, or “hook” functions at various points during the life of the system. They provide central gathering points for applications to trigger on system-wide events such as start-up, disk-save, and so on.

An action-list is a tagged list of data, to be executed (in some sense) in sequence whenever the circumstance identified by its tag occurs. It is expected that whatever code detects or causes the circumstance will take care of running the action-list.

An execution-function can be specified for the action-list when it is created. Otherwise, the default behavior is to treat the data of each action as a callable and apply it to any additional arguments specified at execution time. At its simplest, an action-list emulates (`map nil 'funcall`).

Names of action-lists and action-items are general lisp objects, compared with `equalp`. This allows strings and other objects to be used as unique identifiers.

Actions can be specified to depend on other actions; when defining an action-item, you can say that it must be before or after other action-items using the `:before` and `:after` keywords. Aside from that, actions are assumed to have no dependencies, and no order of execution should be counted on for the actions in a list.

You can (and are encouraged to) specify a documentation string for action-lists or action-items.

In addition you can create action-lists that are not registered globally. This allows applications to have disembodied action lists for their own internal purposes. The other action-list functions allow an action-list to be passed in instead of a name, to accommodate this.

## 8.1 Defining action lists and actions

Action lists are defined using the `define-action-list` macro, and are undefined using the `undefine-action-list`. It is also possible to make unnamed, unregistered lists using `make-unregistered-action-list`.

When defining an action-list, the user may provide an associated execution-function. When executing the action-list, this user-defined execution-function is used instead of the default execution-function, to map over and “execute” the action-list's action-items. The macro `with-action-list-mapping` provides facilities to map over action-items (that is, their corresponding “data”). In addition, the macro `with-action-list-mapping` provides a simple mechanism to trap errors and print warnings while executing each action-item.

Actions are added to an action list using `define-action`, and are removed using `undefine-action`.

## 8.2 Exception handling variables

Three global variables control the handling of exceptions in action list and action item operations.

The variable `*handle-existing-action-list*` controls the behavior of `define-action-list` when the action list already exists. It allows you to control independently both:

- whether you are notified, and
- whether the action list gets redefined

The variable `*handle-existing-action-in-action-list*` controls the behavior of `define-action` when the action already exists in the given action-list. It allows you to control independently both:

- whether you are notified, and
- whether the action item gets redefined

The variable `*handle-missing-action-list*` specifies behavior when one of `undefine-action-list`, `print-actions`, `execute-actions`, `define-action` and `undefine-action` is called on a missing action-list. By default, an error is signaled, but you can make it warn or ignore instead.

The variable `*handle-missing-action-in-action-list*` specifies behavior when you attempt to undefine a missing action. By default, a warning is signaled, but you can make it signal error, or ignore, instead.

## 8.3 Other variables

The variable `*default-action-list-sort-time*` specifies when actions in action-lists are sorted. By default actions are sorted at the time of execution of the action list, but you can cause them to be sorted at action definition time instead.

See `define-action-list` for an explanation of ordering specifiers.

## 8.4 Diagnostic utilities

Two diagnostic functions are provided:

- `print-actions` prints out the actions on a specified action list
- `print-action-lists` prints a list of all the defined action lists

## 8.5 Examples

This example illustrates “typical” use of action lists. The `define-action` forms might be scattered across several files (`mail-utilities.lisp`, `caf-define.lisp`, and so on). Each of the functions, such as `read-mail`, `dont-panic`, and so on, take one argument: `hassled-p`.

```
(in-package "CL-USER")
```

```

(define-action-list "On arrival at office"
  :documentation "Things to do in the morning"
  :dummy-actions '("Look busy")
  :default-order '(:before "Look busy"))

(define-action "On arrival at office" "Read mail" 'read-mail)

(define-action "On arrival at office" "Greet co-workers"
  'say-hello)

(define-action "On arrival at office" "Drink much coffee"
  'wake-up:after "Locate coffee machine")

(define-action "On arrival at office" "Locate coffee machine"
  'dont-panic)

(defun my-morning (hassled-p Monday-p)
  (execute-actions ("On arrival at office"
    :ignore-errors-p Monday-p)
    hassled-p)
  <rest of my-morning code goes here>
)

```

This example illustrates use of execution-functions and post-processing

```
(in-package "CL-USER")
```

Here are the implementation details, which are hidden from the “user”.

```

(defstruct (thing (:constructor make-thing (name number)))
  name
  number)

(defvar *things*
  (make-unregistered-action-list :sort-time :define-action
    :execution-function 'act-on-things))

(defun do-things (function &optional post-process)
  (execute-actions (*things* :post-process post-process)
    function))

(defun act-on-things (things other-args-list &key post-process)
  (with-action-list-mapping
    (things ignore thing post-process)
    (destructuring-bind
      (function) other-args-list
      (funcall function thing))))

```

The interface is given below. The internals of the mapping mechanism are hidden.

```
(defmacro define-thing (name number)
  (with-unique-names (thing)
    `(let ((,thing (make-thing ,name ,number)))
       (define-action *things* ',name ,thing)))))

(defmacro undefine-thing (name)
  `(~(undefined-action *things* ,name) ,))

(defun find-thing (name)
  (do-things #'(lambda (thing)
                  (and (equal name (thing-name thing))
                       thing))
              :or))

(defun add-things ()
  (reduce '+ (do-things 'thing-number :collect)))
```

## 8.6 Standard Action Lists

The following action lists are defined in LispWorks as shipped:

**"When starting image"** - Actions to be executed upon image startup.

**"Confirm when quitting image"** - Actions to be executed before the image quits. Every action must return non-nil as its first value, otherwise the quit will be aborted once the actions are complete.

**"When quitting image"** - Actions to be executed when the image quits, after success of the "Confirm when quitting image" actions.

**"Initialize LispWorks Tools"** - Things to do when the LispWorks IDE starts on a screen. You may customize your environment startup by defining actions on it.

**"Delivery Actions"** - Actions to be executed when doing delivery. Actions on this list are executed in a 'normal' environment. See the *Delivery User Guide* for an example action item.

**"Save Session Before"** - Actions executed before saving a session. See `save-current-session` for details.

**"Save Session After"** - Actions executed after saving a session and redisplaying all the windows. These actions are executed both in the saving image and in the saved image when restarted. See `save-current-session` for details.

## The Compiler

The compiler translates Lisp forms and source files into binary code for the host machine. A compiled Lisp function, for instance, is a sequence of machine instructions that directly execute the actions the evaluator would perform in interpreting an application of the original source lambda expression. Where possible the behaviors of compiled and interpreted versions of the same Lisp function are identical. Unfortunately the definition of the Common Lisp language results in certain unavoidable exceptions to this rule. The compiler, for instance, must macroexpand the source before translating it; any side effects of macro-expansion happen only once, at compile time.

By using declarations, you can advise the compiler of the types of variables local to a function or shared across an application. For example, numeric operations on a variable declared as a `single-float` can be compiled as direct floating-point operations, without the need to check the type at execution time. You can also control the relative emphasis the compiler places on efficiency (speed and space), safety (type checking) and support for debugging. By default the compiler produces code that performs all the necessary type checking and includes code to recover from errors. It is especially important that the type declarations be correct when compiling with a safety level less than 3 (see later in this chapter for more details).

When compiling a Lisp source file, the compiler produces its output in a format that is much faster to load than textual Lisp source — the “fasl” or “fast-

load” form. Fasl files contain arbitrary Common Lisp objects in a pre-digested form. They are loaded without needing to use the expensive `read` function. A series of “fasl-loader” routines built into LispWorks interpret the contents of fasl files, building the appropriate objects and structures in such a way that objects that were `eq` before fasl-dumping are created `eq` when fasl-loaded.

Fasl files are given pathname extensions that reflect the target processor they were compiled for; as the fasl files contain processor specific instruction sequences it is essential that the loader be able to distinguish between files compiled for different targets. These pathname extensions always end in “fasl”. See `compile-file` for details of all the possible fasl file extensions.

## 9.1 Compiling a function

The function `compile` takes a symbol as its first argument, and an interpreted function definition (a lambda expression) as its second, optional, argument. It compiles the definition and installs the resultant code as the symbol-function of the symbol (unless the symbol was `nil`). If the definition is omitted then the current symbol-function of the symbol is used. Below are some examples:

```
CL-USER 3 > (compile (defun fred (a b)
                               (dotimes (n a) (funcall b))))
; FRED
FRED
NIL
NIL

CL-USER 4 > (funcall (compile nil '(lambda (n)
                                         (* n n))) 7)
; NIL
49

CL-USER 5 > (compile 'ident-fun '(lambda (x) x))
; IDENT-FUN
IDENT-FUN
NIL
NIL
```

## 9.2 Compiling a source file

The function `compile-file` takes a pathname as its argument and compiles all the forms in the file, producing a corresponding fasl file (with pathname derived from the source pathname). Any side effects in the source file are only felt once the compiled file is subsequently loaded. Many proclamations, for example, are not visible at compile time. The special form `eval-when` can be used to force such side effects to take effect at the time of compilation, rather than loading.

## 9.3 Compiling a form

To compile an arbitrary form *form* (as opposed to a function), call

```
(compile form)
```

This compiles *form* as if by `compile-file` but without any file related processing and does it in-memory, so it has also the same effect as loading. This has a similar effect to compiling a definition in the LispWorks Editor tool, except that there is no source recording.

Using `compile` this way is especially useful if you need to dynamically define something that is normally defined by a top level or, for example `kw: defrule`.

## 9.4 How the compiler works

Conceptually the compiler can be viewed as performing a series of separate passes.

- In the first pass the source code is macro expanded in the appropriate macro environment.
- A series of source to source optimizing transformations are performed to simplify the source tree. Type declarations are used to select specialized, efficient versions of low level functions.
- A graph is generated from the source tree. The structure of the graph reflects the flow of control in the tree. The nodes of the graph contain blocks of intermediate code for an abstract machine with byte addressing and an infinite set of registers. Register allocation is performed

based on data flow analysis and machine specific rules concerning live ranges across code fragments.

- The blocks of intermediate code are translated into a single linear sequence of target machine code through a process of template matching.
- Finally the relative branch instructions are “fixed up” to point to the correct locations in the code sequence.

The compiler is in fact much more complex than this model might suggest. Machine specific optimizations, for example, can be included in any of the passes. The distinction between passes is also not as simple as that listed above. However, this description is sufficient to allow the programmer to make optimal use of the compiler.

## 9.5 Compiler control

There are ways to control the nature of compiled code via the `declare` special form and `proclaim` function. See “Declare, proclaim, and declaim” on page 109 for fuller discussion of these two forms.

In particular there are a set of optimize qualities which take integral values from 0 to 3. These control the trade-offs between size, speed, retention of debug information, optimizations and safety (that is, type checks) in the resulting code, and also compilation time. For example:

```
(proclaim '(optimize (speed 3) (safety 0) (debug 0)))
```

tells the compiler to concentrate on code speed rather than anything else, and

```
(proclaim '(optimize (safety 3)))
```

ensures that the compiler never takes liberties with Lisp semantics and produces code that checks for every kind of error that can be signaled.

The important declarations to the compiler are type declarations and optimize declarations. To declare that the type of the value of a variable can be relied upon to be unchanging (and hence allow the compiler to omit various checks in the code), say:

```
(declare (type the-type variable * ))
```

Optimize declarations have various qualities, and these take values from 0 to 3. The names are `safety`, `fixnum-safety`, `float`, `sys:interruptable`, `debug`, `speed`, `compilation-speed`, and `space`.

Most of the qualities default to 1 (but `safety` and `fixnum-safety` default to 3 and `interruptable` defaults to 0). You can either associate an optimize quality with a new value (with local lexical scope if in `declare`, and global scope if `proclaim`), or just give it by itself, which implies the value 3 (taken to mean “maximum” in some loose sense).

Thus you ensure code is at maximum safety by:

```
(proclaim '(optimize (safety 3)))
```

or

```
(proclaim '(optimize safety))
```

and reduce debugging information to a minimum by

```
(proclaim '(optimize (debug 0)))
```

Normally code is interruptible, but when aiming for maximum speed and minimum safety and debug information code is not interruptible unless you ensure it thus:

```
(proclaim '(optimize (debug 0) (safety 0) (speed 3)
                     interruptable))
```

The levels of `safety` have the following implications:

- 0 implies no type checking upon reading or writing from defstructs, arrays and objects in general, nor any checking of array index bounds.
- 1 implies no type checking upon reading from defstructs, arrays and objects in general, nor any checking of array index bounds when reading. However, array index bounds are checked when writing.
- 2 implies type checking when writing, but not when reading. Other than this the compiler generates generally safe code, but allows `type` and `fixnum-safety` declarations to take effect. Array index bounds are checked for both reading and writing.
- 3 (default) implies complete type and bounds checking, and disallows `fixnum-safety` and `type` declarations from taking any effect.

The levels of `fixnum-safety` have the following implications:

- 0 implies no type checking of arguments to numeric operations, which are assumed to be fixnums. Also the result is assumed, without checking, to not overflow - this level means single machine instructions can be generated for most common integer operations, but risks generating values that may confuse the garbage collector.
- 1 implies that numeric operations do not check their argument types (assumed fixnum), but do signal an error if the result would have been out of range.
- 2 implies that numeric operations signal an error if their arguments are non-fixnum, and also check for overflow.
- 3 (default) implies complete conformance to the semantics of Common Lisp numbers, so that types other than integers are handled in compiled code.

Additionally if the level of `float` (really this should be called “float-safety”) is 0 then the compiler reduces allocation during float calculations.

The effects of combining these qualities is summarized below:

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>safety=0</code>	Array access optimizations
<code>debug&gt;0</code>	Dumps symbol names for arglist
<code>debug&gt;=2</code>	Ensure debugger knows values of args (and variables when source level debugging is on) and can find the exact subform in the Editor.
<code>debug&lt;1</code>	Does not generate any debug info at all
<code>debug=3</code>	Avoids <code>make-instance</code> and <code>find-class</code> optimizations
<code>debug=3</code>	Avoids <code>gethash</code> and <code>puthash</code> optimizations
<code>debug=3</code>	Avoids <code>ldb</code> and <code>dpb</code> optimizations

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>debug=3</code>	Avoids an optimization to <code>last</code>
<code>safety&gt;1</code>	Be careful when multiple value counts are wrong
<code>safety&lt;1</code>	Do not check array indices during write
<code>safety&lt;2</code>	Do not check array indices during read
<code>speed&gt;space</code>	Inline map functions (unless <code>debug&gt;2</code> )
<code>debug&lt;=2</code>	Optimize (merge) tail calls
<code>debug&lt;2 and safety&lt;2</code>	Self calls
<code>safety&gt;=2</code>	Check get special
<code>safety&lt;2</code>	Do not check types during write
<code>safety&lt;3</code>	Do not check types during read
<code>safety&gt;=1</code>	Check structure access
<code>safety&lt;=1</code>	Inline structure readers, with no type check
<code>safety=0</code>	Inline structure writers, with no type check
<code>safety&gt;1</code>	Check number of args
<code>safety&gt;=1 or interruptible&gt;0</code>	Check stack overflow
<code>safety&gt;1</code>	Ensures the thing being funcalled is a function
<code>safety&lt;3 and fixnum-safety=2</code>	Fixnum-only arithmetic with errors for non fixnum arguments.
<code>safety&lt;3 and fixnum-safety=1</code>	No fixnum overflow checks
<code>safety&lt;3 and fixnum-safety=0</code>	No fixnum arithmetic checks at all
<code>safety&gt;2</code>	<code>char=</code> checks for arguments of type <code>character</code>
<code>safety&gt;=2</code>	Ensures symbols in <code>progv</code>

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>debug=3</code>	Avoids “ad hoc” predicate type transforms
<code>compilation-speed=3</code>	Reuse virtual registers in very large functions
<code>debug=3 and safety=3</code>	( <code>declare (type foo x)</code> ) and ( <code>the foo x</code> ) ensure a type check
<code>float=0</code>	Optimize floating point calculations

The other optimize qualities are: `speed` — the attention to fast code, `space` — the degree of compactness, `compilation-speed` — speed of compilation, `interruptable` — whether code must be interruptible when unsafe.

Note that if you compile code with a low level of safety, you may get segmentation violations if the code is incorrect (for example, if type checking is turned off and you supply incorrect types). You can check this by interpreting the code rather than compiling it.

### 9.5.1 Examples of compiler control

The following function, compiled with safety = 2, does not check the type of its argument because it merely reads:

```
(defun foo (x)
  (declare (optimize (safety 2)))
  (car x))
```

However the following function, also compiled with safety = 2, does check the type of its argument because it writes:

```
(defun set-foo (x y)
  (declare (optimize (safety 2)))
  (setf (car x) y))
```

As another example, interpreted code and code compiled at a low safety does not check type declarations. To make LispWorks check declarations, you need to compile your code after doing:

```
(declaim (optimize (safety 3) (debug 3)))
```

This last example shows how to copy efficiently bytes from a typed-aref vector (see `make-typed-aref-vector`) to an (`unsigned-byte 8`) array. `type` and `safety` declarations cause the compiler to inline the code that deals specifically with (`unsigned-byte 8`). This code was developed after an application was found to have a bottleneck in the original version of this function:

```
(defun copy-typed-aref-vector-to-byte-vector
  (byte-vector typed-vector length)
  (declare (optimize (safety 0))
           (type (simple-array (unsigned-byte 8) 1) byte-vector)
           (fixnum length))
  (dotimes (index length)
    (declare (type fixnum index))
    (setf (aref byte-vector index)
          (sys:typed-aref '(unsigned-byte 8)
                          typed-vector index))))
```

## 9.6 Declare, proclaim, and declaim

The special form `declare` is used to:

- declare Lisp variables as “special”, which affects the semantics of the appropriate bindings of the variables, or
- help the system (in reality the compiler) run your Lisp code faster, or
- make the code run with more sophisticated debugging options, or
- help you optimize your code

`declare` behaves computationally as if it is not present (other than to affect the semantics), and is only allowed in certain contexts, such as after the variable list in a `let`, `do`, `defun` and so on. Consult the syntax definition of each special form to see if it accepts `declare` forms.

For the details, including some LispWorks extensions to Common Lisp, see the reference entry for `declare`.

The function `proclaim` parses declarations in a specified list and then puts their semantics and advice into global effect. This can be useful when compiling a file for speedy execution, since a proclamation such as:

```
(proclaim '(optimize (speed 3) (space 0) (debug 0)))
```

causes the rest of the file to be compiled with these optimization levels in effect. (A lengthier way to do this is to make appropriate declarations in every function in the file.) Below are some more examples:

```
(proclaim '(special *fred*))  
(proclaim '(type single-float x y z))  
(proclaim '(optimize (safety 0) (speed 3)))
```

Do not forget to quote the argument list if it is a constant list. This form:

```
(proclaim (special x))
```

attempts to call function `special`.

`declaim` is a macro equivalent to `proclaim`.

### 9.6.1 Naming conventions

Exercise caution if you `declare` or `proclaim` variables to be special without regard to the naming convention that surrounds their names with asterisks.

## 9.7 Optimizing your code

Careful use of the compiler optimize qualities described above or special declarations may significantly improve the performance of your code. However it is not recommended that you simply experiment with the effect of adding declarations. It is more productive to work systematically:

1. Use the Profiler, described in Chapter 12, “The Profiler”, to analyze your application’s performance and identify bottlenecks, then
2. Consider whether re-writing of parts of your source code would improve efficiency at the bottlenecks, and
3. Use `:explain` declarations to make the compiler generate optimization hints, and
4. (In SMP LispWorks) use `analysing-special-variables-usage` to report on symbols proclaimed special, and
5. Consider adding suitable declarations as described in this chapter to improve efficiency at the bottlenecks.

The most important tool for speeding up programs is the Profiler. You use the profiler to find the bottlenecks in the program, and then optimize these bottlenecks by helping the compiler to produce better code.

The remainder of this section describes some specific ways to produce efficient compiled code with LispWorks.

### 9.7.1 Compiler optimization hints

You can make the compiler print messages which will help you to optimize your code. You add suitable `:explain` declarations, recompile the code, and check the output.

The full syntax of the `:explain` declaration is documented in the reference entry for `declare`.

Various keywords allows you to see information about compiler transformations depending on type information, allocation of floats and bignums, floating point variables, function calls, argument types and so on. Here is a simple example:

```
(defun foo (arg)
  (declare (:explain :variables) (optimize (float 0)))
  (let* ((double-arg (coerce arg 'double-float))
         (next (+ double-arg 1d0))
         (other (* double-arg 1/2)))
    (values next other)))
;;- Variables with non-floating point types:
;;- ARG OTHER
;;- Variables with floating point types:
;;- DOUBLE-ARG NEXT
```

**Note:** the LispWorks IDE allows you to distinguish compiler optimization hints from the other output of compilation, and also helps you to locate quickly the source of each hint. For more information see the chapter “The Output Browser” in the *LispWorks IDE User Guide*.

### 9.7.2 Fast integer arithmetic

You can arrange for compiled code to perform optimal raw 32-bit arithmetic, and additionally in 64-bit LispWorks, optimal raw 64-bit arithmetic.

For all the details, see “Fast 32-bit arithmetic” on page 472 and “Fast 64-bit arithmetic” on page 474.

### 9.7.3 Floating point optimization

The declaration `float` allows generation of more efficient code using float numbers. It reduces allocation during float calculations. It is best used with safety 0. That is, you declare `(optimize (float 0) (safety 0))` as in this example:

```
(progn
  (setf a
        (make-array 1000
                   :initial-element 1D0
                   :element-type 'double-float))
  nil ; to avoid printing the large array
  )

(compile
  (defun test (a)
    (declare (optimize (speed 3) (safety 0) (float 0)))
    (declare (type (simple-array double-float (1000))
                  a))
    (let ((sum 0D0))
      (declare (type double-float sum))
      (dotimes (i 1000)
        (incf sum (the double-float (aref a i))))
      sum))

  (time (test a))
=>
Timing the evaluation of (TEST A)

  user time      =      0.000
  system time    =      0.000
  Elapsed time  =  0:00:00
  Allocation    = 16 bytes standard / 0 bytes conses
  0 Page faults
```

**Note:** In some cases, the operations cannot be fully optimized with `float 0`, which can cause the compiled code to be larger because the unboxing and boxing of floats will be inline.

### 9.7.4 Tail call optimization

In 64-bit LispWorks and on x86 platforms the compiler optimizes tail calls unless

1. The compiler optimize quality `debug` is 3, or
2. There is something with dynamic scope on the stack, such as a special binding, a catch or `c1:dynamic-extent` allocation (so it is not really a tail call)

On all other platforms the compiler optimizes tail calls unless 1.) or 2.) above apply, or

3. The call has more than 4 arguments and this is more than the number of fixed (not `&optional`/`&rest`/`&key`) parameters in the calling function.
4. The call has more than 4 arguments and the calling function has `&rest`/`&key` parameters.

### 9.7.5 Usage of special variables

The declaration `c1:special` specifies that a variable is special, that is it does not have lexical scope. This covers two cases: if the variable is bound in the dynamic environment (for example by `let` or `let*`), then the value of that binding is used; otherwise the value in the global environment is used, if any. An error is signaled in safe code if there is no value in either environment.

When `setq` is used with a variable, the value in the dynamic environment is modified if the variable is bound in the dynamic environment, otherwise the value in the global environment is modified. Dynamic variables can have a different value in each thread because each thread has its own dynamic environment. The global environment is shared between all threads.

In SMP LispWorks access to special variables (excluding constants) is a little slower than in non-SMP LispWorks. It can be made to run faster by declarations of the symbol, normally by using `proclaim` or `declare`.

The speedup will be pretty small overall in most cases, because access to specials is usually a small part of a program. However, if the Profiler identifies some piece of code as a bottleneck, you will want to optimize it, and your optimizations may include proclamation of some variable as global or dynamic.

The three declarations described in this section are extensions to Common Lisp. All declare the symbol to be `cl:special`, along with other information. These three declarations are mutually exclusive between themselves and `cl:special`. That is, declaring a symbol with any of these declarations eliminates the other declaration:

- `hcl:special-global` declares that the symbol is never bound in the dynamic environment.

In SMP LispWorks the compiler signals error if it detects that a symbol declared as `hcl:special-global` will be bound in the dynamic environment, and at run time it also signals an error.

In non-SMP LispWorks the compiler gives an error, but there is no run time check. The run time behavior is the same as `cl:special`, with all accesses to the symbol in low safety.

`hcl:special-global` is very useful, and because of the checks it is reasonably safe. It is useful not only for speed, but also to guard against unintentionally binding variables that should not be bound.

See also `defglobal-parameter`.

- `hcl:special-dynamic` declares that the symbol is always bound in the dynamic environment when it is accessed.

In high safety code accessing the symbol when it is not bound in the dynamic environment signals an error. In low safety code it may result in unpredictable behavior.

In non-SMP LispWorks the only effect of this declaration is to make all access to the variable low safety.

`hcl:special-dynamic` is useful, but because it can lead to unpredictable behavior you need to ensure that you test your program in high safety when you use it.

- `hcl:special-fast-access` declares that a symbol should be "fast access".

The semantics of the declaration is the same as `c1:special`, except that access to the variable is low safety. In addition, the compiler compiles access to the symbol in a way that speeds up the access, but also introduces a tiny reduction in the speed of the whole system. The balance between these effects is not obvious.

It is not obvious where `hcl:special-fast-access` is useful. If you can ensure that the symbol is always bound or never bound then `hcl:special-dynamic` or `hcl:special-global` are certainly better.

### 9.7.5.1 Finding symbols to declare

The macro `analysing-special-variables-usage` can be used to find symbols that may be proclaimed global, which can improve performance. `analysing-special-variables-usage` also helps to identify inconsistencies in the code.

### 9.7.5.2 Coalesce multiple special bindings

If a set of specials are always bound at the same time, it is better to store the values in a single structure object and bind one special variable to that object, to reduce the overall number of special bindings.

## 9.7.6 Stack allocation of objects with dynamic extent

`(declare dynamic-extent)` will optimize these calls so that they allocate in the stack, in all cases:

- `&rest` lists
- `flet` functions and `labels` functions
- `(cons x y)`
- `(list ...)`
- `(list* ...)`
- `(copy-list x)`
- `(make-list x)`
- `(vector ...)`

(**declare dynamic-extent**) will also optimize these specific calls:

- (**make-array n**)
- (**make-array n :initial-element x**) without any other arguments
- (**make-foo ...**) where **make-foo** is an inline structure constructor.  
The default constructor is declared inline automatically when none of the **defstruct** slot initforms are calls to functions.
- (**make-string n :element-type 'base-char**)
- (**(system:make-typed-aref-vector n)**)

### 9.7.7 Inlining foreign slot access

Given a structure definition

```
(fli:define-c-struct foo-struct
  (a :int)
  (b :int))
```

you can inline access to a slot by declaring **fli:foreign-slot-value** inline and supplying the *object-type*:

```
(defun foo-a (struct)
  (declare (inline fli:foreign-slot-value))
  (fli:foreign-slot-value struct 'a :object-type 'foo-struct))
```

### 9.7.8 Built-in optimization of remove-duplicates and delete-duplicates

LispWorks optimizes **cl:remove-duplicates** and **cl:delete-duplicates** for lists when the *test* or *test-not* is one of a small set of known functions. These functions are currently **cl:eq**, **cl:equal**, **cl:equalp**, **cl:=**, **cl:string=**, **cl:string-equal**, **cl:char=** and **cl:char-equal**.

## 9.8 Compiler parameters affecting LispWorks

There are six compiler parameters that control the generation of information used by various LispWorks utilities, such as the debugger, and also by various editor commands, such as **Show Paths From**. By default, these parameters are all **t**, which allows you to use all the features of these utilities, at the expense of increasing compilation times.

These variables are initially set to `t` (in the LispWorks file `config/a-dot-lispworks.lisp`). To speed up compilation times, you should set these variables to `nil`. The variables can be controlled as a group by using the function `toggle-source-debugging`.

It is also possible to compile your code with counters or flags such that you can see which parts of your program have actually executed at run time, as described in Chapter 10, “Code Coverage”.

# 10

---

# Code Coverage

Code Coverage in LispWorks allows you to compile your code with code execution counters, which then record when each piece of code is executed, and then display which parts of the program were executed and how frequently. Alternatively you can compile your code with a binary flag to record simply whether each piece was executed or not.

## 10.1 Using Code Coverage

Using Code Coverage involves four steps, described in this section:

1. Compiling the code to record code coverage information.
2. Loading the code.
3. Exercising the code.
4. Displaying the results.

Optionally, you can get a copy of the results and manipulate these before displaying them, as described in “Manipulating code coverage data” on page 121.

### 10.1.1 Compiling the code to record code coverage information

Switch on generation of Code Coverage by either calling `generate-code-coverage` (which switches it globally), or using the macro `with-code-coverage-generation` (which switches it on only within the dynamic scope of the macro). Then compile your file(s) by calling `compile-file`. Alternatively you can use something that calls `compile-file` such as `compile-system`, menu command **File > Compile...** or the editor command **Compile File**.

Code Coverage works only when compiling into binary files, rather than into memory (which is what some editor commands such as `Compile Buffer` do).

When `compile-file` is called with code coverage generation, it generates code that keeps track of execution and contains some extra data. This results in slightly slower code and larger binary files that use more memory when loaded.

### 10.1.2 Loading the code

Load your compiled files as usual by calling `c1:load`. Alternatively you can use something that calls `c1:load` such as `load-system`, menu command **File > Load...** or the editor command **Load File**.

When a file that was compiled with code coverage generation is loaded, it automatically adds itself to the internal `code-coverage-data` structure (over-writing existing data), and from that point any access to this structure (see below) will include information about the code in this file. Executing code that was compiled with code coverage generation always updates the internal `code-coverage-data` structure (it is not switchable).

### 10.1.3 Exercising the code

Decide what you want to check, and run the entry points.

Code Coverage measures which parts of the program were executed, so you need to decide what you want to check and call the entry points. In a graphical application, you need to display the main window and interact with it.

### 10.1.4 Displaying the results

There are two ways to view the results:

- as HTML files in a web browser, or
- with the Editor and Code Coverage Browser tools in the LispWorks IDE.

HTML display is done by calling `code-coverage-data-generate-coloring-html`, which in general generates one HTML file per source file in the `code-coverage-data`, and also an index HTML file with hyperlinks to all of them. Editor display is done by the function `editor-color-code-coverage`, which takes the name of a source file and creates a new editor buffer with the source colored according to the code coverage. Both functions take various keywords to control what they actually do. By default, both of them use the internal `code-coverage-data` structure, but can also use a manipulated `code-coverage-data`. See `code-coverage-data-generate-coloring-html` and `editor-color-code-coverage` for full details.

## 10.2 Manipulating code coverage data

Optionally you can manipulate `code-coverage-data` before displaying it, using the functions described in this section.

The `code-coverage-data` structure contains information about some set of files. Except for the internal `code-coverage-data`, this information does not change. The internal `code-coverage-data` object is updated whenever code that was compiled with code coverage runs. Also, when a binary file that was compiled with code coverage is loaded it adds itself to the internal `code-coverage-data` (overwriting any existing data associated with that file). Most of the functions for manipulating `code-coverage-data` can operate on the internal `code-coverage-data` structure by passing `t` as the data argument. See the specific functions for details.

The interface to code coverage data allows you to:

- Copy `code-coverage-data`, save it into a file, and load a `code-coverage-data` from a file.

These functions are `copy-code-coverage-data`, `copy-current-code-coverage`, `merge-code-coverage-data`, `filter-code-coverage-data`, `save-code-coverage-data`, `save-current-code-coverage` and `load-code-coverage-data`.

- Add or subtract two `code-coverage-data` structures. This means add or subtract all the corresponding counters from the two structures. This is allowed only if all the files that are in both structures are from the same compilation.

For example, you may subtract the data of one test from another to see how they differ in the way they use their code.

These functions are `add-code-coverage-data`, `destructive-add-code-coverage-data`, `subtract-code-coverage-data`, `destructive-subtract-code-coverage-data`, `reverse-subtract-code-coverage-data` and `destructive-reverse-subtract-code-coverage-data`.

- Clear the internal `code-coverage-data` (this means eliminating the files from it) or reset it (this means setting the counters to 0), or setting to another `code-coverage-data`.

These functions are `clear-code-coverage`, `reset-code-coverage` and `restore-code-coverage-data`.

- Set an internal snapshot, and later compare with it.

These functions are `set-code-coverage-snapshot`, `get-code-coverage-delta` and `reset-code-coverage-snapshot`.

- Generate statistics about the contents of the code coverage, by `code-coverage-data-generate-statistics`.

### 10.3 Preventing code generation for some forms

You can use the macros `error-situation-forms` and `without-code-coverage` to prevent generation of code coverage inside their body. For example, explicit calls to `c1:error` that are not expected to happen can be marked not to be counted. The system uses these in macros that call `c1:error` such as `c1:etypecase` and `c1:assert`.

## 10.4 Code coverage and multithreading

By default, code compiled with code coverage uses non-atomic counters, which means that if the code runs in multiple threads it will occasionally drop a count. As the count is mostly used as heuristics this is usually not a problem (it will never drop all the counts, so you will not get 0 counts when there should be more than 0).

To record an exact count you can compile with `atomic-p t` (see `generate-code-coverage` and `with-code-coverage-generation`). Atomic incrementing may make the program run much more slowly, which is the reason that it is not the default behavior.

The `code-coverage-data` manipulation functions are thread-safe, and will not corrupt data or cause errors when running in parallel. However they are not atomic, so modifying the same structure in parallel will create inconsistent data. Reading the internal data while code with counters is executing may also generate an inconsistent data.

## 10.5 Counting overflow

The code coverage counters are 32-bit signed values (signed to allow negative values, which you can get when subtracting). Long tests can overflow in their frequently-called functions. That means that for these functions the counter is not that useful anymore. Also, you can end up on exactly 0, which looks as if the code was not executed. For heuristics that seems not to be a problem.

To avoid these problems with counter overflow, you can compile with a binary flag (initial value 0) instead of the counter. The flag switches to 1 when the code is called (see `generate-code-coverage` and `with-code-coverage-generation`). This loses the counting, but also generates smaller and faster code and uses less memory.

## 10.6 Memory usage and code speed

Collecting code coverage information makes the code larger and slower, but still workable. Compiling with binary flags results in code that is faster and smaller than code compiled with counters (see `generate-code-coverage` and `with-code-coverage-generation`) and it also reduces the size of the

data that `code-coverage-data` needs to keep. On the other hand you lose the counters, but if you do not need the counters it may be useful.

## 10.7 Understanding the code coverage output

In general there are five colors that are used to color the source code. Below these are named by the keyword argument to `code-coverage-set-html-background-colors` that changes them for the HTML coloring, and the default color is shown in parentheses:

*fully-covered* (Green)

Forms where every part was covered, that is all of the source subforms were executed.

*partially-covered* (GreenYellow)

Forms that are partially covered in a visible way, that is some of the source subforms were not executed.

*hidden-partial* (Orange)

Forms that are partially covered in a non-visible way, that is all the source subforms were executed, but some of them were expanded to forms that were not completely executed.

*uncovered* (Pink)

Uncovered forms, that is forms that were never executed.

*eliminated* (DeepPink)

Forms that were completely eliminated by the compiler.

Note that by default only *hidden-partial*, *uncovered* and *eliminated* are shown, so all colored forms indicate something that was not covered. However, inside a *hidden-partial* form the *fully-covered* subforms are always colored, regardless of the setting of *fully-covered*.

When counters are displayed, they have their own background color *counters* (MediumAquamarine), except for negative counters that use color *counters-negative* (Gold). In addition the colors *error* (Red) and *warn* (Yellow) are used when adding error or warning messages.

### 10.7.1 Eliminated forms

The compiler eliminates forms that it determines are not needed. These include:

- Forms that have no side effects and whose result is not used.
- Forms that will never be reached.

To deduce that code does not have side effects, the compiler needs to know that the function calls in it have no side effects. The only function calls that the compiler knows to be free of side effects are either system functions or automatically defined functions such as structure accessors.

Unreachable code can happen explicitly but it can also happen implicitly, when the compiler eliminates it. The commonest case is when the compiler uses type inference to infer what a predicate will return. For example, suppose you have this definition:

```
(defun my-func (arg)
  (let ((sum (+ arg 10)))
    (if (consp sum)
        (car sum)
        (* sum 7))))
```

Since `sum` is a result of the call to `+` it must be a number and therefore cannot be a cons. Hence the compiler can infer that the `consp` call will always return `nil`, replace the call to `consp` by `nil`, eliminate the call to `car`, and go straight to the `*` call. In the coloring, the call to `car` will be shown as *eliminated*, while the `if` form will be shown as *fully-covered*. That is a little counter-intuitive, because the `if` and the `consp` are not actually in the compiled code, but they were effectively evaluated by the compiler at compile time.

### 10.7.2 Displaying counters

By default, code coloring adds counters, indicating how many times a point in the code has been executed. Note that counts may also be negative, when the code coverage data that is displayed is the difference between datas (as generated by functions like `subtract-code-coverage-data`). When a count is 0 the counter is not displayed.

By default, if the counter for a subform is the same as the counter of the parent form, the counter for that subform is not displayed. Thus when you see a sub-

form without a counter, it means it was executed the same number of times as its parent. The counter is displayed even if it is the same in situations when the code coverage status of the forms is different, for example if the parent is *partially-covered* but the subform is *fully-covered*.

It is possible to force all counters to be displayed, by passing `:show-counters :all` to `code-coverage-data-generate-coloring-html` and the other displaying functions. Note that the compiler does not generate counters for forms that it can deduce will be always executed the same number of times as the parent, so for these it will never display counters.

### 10.7.3 Function forms where the function is not actually called

Entering a function form does not necessarily call the function, because during evaluation of the arguments there may be an exit out of the form. This exit can be local or non-local, and in general the compiler cannot tell whether it will happen or not, though it can be sure that it will not happen for specific cases like local variable references and self-evaluating forms. Therefore the compiler adds a counter just before the function is called. It is not obvious how to display this counter, and when it is 0 what part of the form has not been executed.

The current coloring regards the function name as the part of the form that is "being evaluated" when the function is actually called. Therefore it inserts the counter before the function name, and if it is 0 it colors the function name in the *uncovered* color. That means that in some cases you have a counter before the opening parenthesis that counts the times that the form was entered, and a counter after the opening parenthesis that counts the times that the function was called. Since the coloring normally skips counters that are inside a form where they have the same count as the counter of the form, you will see both numbers only when they are different.

### 10.7.4 Partially hidden

Partially hidden forms are forms where all the source code as shown was executed, but some macro expansion of it contains a conditional where one of the branches was not executed. Thus there is not any specific form to color as uncovered, but some part of the actual code was not executed. These forms are colored by a special color *hidden-partial*, which is Orange by default.

For example, if you have this code:

```
(defmacro did-it-p ()
  '(if *done* nil t))

(defun go-next-p ()
  (did-it-p))
```

and whenever `go-next-p` is called `*done*` is true, then the false branch of the `if` form was not executed, but inside the definition of `go-next-p` there is no source that was not executed. Thus the form `(did-it-p)` is partially hidden.

Partially hidden forms can have subforms that are fully covered. These forms are colored by the color *fully-covered* even if fully covered forms are not colored otherwise (the default behavior), to clarify that they were fully covered.

## 10.8 Coloring code that has changed

The code coverage data does not keep the source code. Instead, it keeps a reference to the code that the reader saw (when called from `compile-file`).

When it adds colors, it re-reads the source file. That means it needs the original source file for coloring. If the source file was modified, it adds a warning in the beginning of the file, but tries to color it anyway.

If what the reader sees has not changed (that is the only changes involve only comments and whitespace) the coloring will work properly. Changes to what the reader sees, however, will confuse the coloring. In general, subforms that are modified are miscolored, but code outside the modified subform colors properly. For a top level form, if you modify it, this form will not color properly, but all the other forms will color properly. If you remove or add a top level form, all the following forms will not color properly. Note that this applies even if you do something like adding (or removing) a `progn` around some forms, which although it does not affect the compiler does cause the reader to see different forms.

Thus if you modify your code, the coloring becomes less reliable. In most cases this is not a big problem, but in many cases it is probably better to copy your source tree and compile the copy with code coverage, so you can continue to modify the source while reviewing the code coverage output.

# 11

---

# Memory Management

This chapter introduces some basic ideas of memory management, and then discusses the LispWorks memory management system in more detail. The chapter also introduces the functions and macros needed to control memory management. Full details of all the symbols mentioned here are given in Chapter 38, “The HCL Package” and Chapter 49, “The SYSTEM Package”.

## 11.1 Introduction

Automatic memory management is one of the most significant features of a Lisp system. Whenever an object, such as a cons cell, is required to hold an aggregate of values, the system calls the appropriate function to create a new object and fill it with the intended values. The programmer need not be concerned with the low level allocation and management of memory as the Lisp system provides this functionality automatically.

When an object is no longer required (that is, it has become “garbage”), the system must automatically reclaim (“collect”) the space it occupies and reallocate the space to a new object. Whenever the space for new objects is exhausted, a “garbage collector” (GC) is run to determine (by a process of elimination) all the existing objects that are still required by the running program. Any other objects still in the image are necessarily garbage, and the space they occupy can be reclaimed.

For a description of how LispWorks uses the address space of different Operating Systems, and factors affecting the maximum image size, see “Address Space and Image Size” on page 458.

Garbage collection with a naive algorithm is extremely inefficient.

The LispWorks GC works in unison with the memory allocator to arrange allocated objects in a series of “generations”. Each generation contains objects of a particular age. In practice most Lisp data objects are only required for a very short period of time. That is, they are ephemeral. The LispWorks GC concentrates its efforts on repeatedly scanning the most recent generation. Such a scan requires only a fraction of a second and reclaims most of the space allocated since the last collection. Any object in the most recent generation that survives a number of such collections is promoted to the next youngest generation. Eventually this older generation becomes full, and only then is it collected. The generations are numbered from 0 upwards, so that generation 0 is the youngest.

The remainder of this chapter describes the LispWorks GC in more detail. The implementation and the programmatic interface differ between 32-bit and 64-bit LispWorks.

## 11.2 Guidance for control of the memory management system

### 11.2.1 General guidance

The memory management is designed with the intention that the programmer will have to do very little or nothing about it. In general, we believe that the design is quite successful, and in most cases you do not have to do anything. The main exception to this is dealing with long-lived data in long-lived processes in 32-bit LispWorks.

Before doing anything about memory management, you should be familiar with the function `room`, and use it frequently. There is no point at all in trying to tune the memory management without knowing the sizes of your application, as output by `room`.

The data and code in the LispWorks image can be categorized according to how long they live, as follows:

1. Short-lived data
2. Long-lived data
3. Permanent data

Note that the distinction is not in the data itself, but in the existence of pointers to it.

In general, you rarely need to worry about short-lived data, and have to worry about permanent data only if you have a large amount of it. In short-lived applications you do not need to worry about long-lived data either, so there is a good chance that you do not have to worry about memory management at all.

In long-lived applications, you certainly need to consider long-lived data in 32-bit LispWorks, and maybe in 64-bit LispWorks.

### 11.2.2 Short-lived data

Normally you should not do anything about handling of short-lived data, because the default settings are good enough for almost all situations. Sometimes you may hit a situation where the settings are not good ("pathological case"). However, it would normally require a deep understanding of the memory management system to deal with such a situation, and we will in general consider this as a bug and try to fix it. Therefore if you find such situation you should report it to Lisp Support, following the guidelines at [www.lisp-works.com/support/bug-report.html](http://www.lisp-works.com/support/bug-report.html).

Problems with short-lived data normally just reduce the performance of some part of your application. Normally the best solution is to optimize the code to do less work, including allocating less.

To do that, first find the bottlenecks in your application by using `profile` (and `start-profiling` and `stop-profiling`). `time` and `extended-time` can then be used to determine how long specific operations take, how much they allocate and, for long operations, how long they spend in garbage collection. Use this information to decide what to try to optimize.

### 11.2.3 Long-lived data

Long-lived data is data that lives long enough to be promoted to the highest generation to which promotion occurs automatically (the "blocking generation"), but later becomes garbage. The blocking generation is 2 in 32-bit LispWorks and (by default) 3 in 64-bit LispWorks.

You can check which generation individual objects are in (by `generation-number`), but normally you want to know the total amount of data in various generations. The function `room` is used for that. In general, it is useful to call

```
(room)
```

and sometimes also

```
(room t)
```

periodically (every 5 minutes) and log the output. In servers, such logs are essential. From this output you can see how the sizes of the various generations change over time.

If the output shows that the blocking generation grows too much, even though permanent data is not added, you will need to do something about it. In 64-bit LispWorks there is a good chance that you do not have to do anything. In 32-bit LispWorks long-lived processes (for example servers) probably need to do something.

The main thing you will do is calling `(gc-generation t)`. This garbage collects the blocking generation. You should check the state of the memory after calling it by calling `room` again. If the amount of allocated data (as opposed to total size) did not reduce, you may have a memory leak that causes accumulation of permanent data that does not die.

If `gc-generation` does free data (that is, the allocation reduces significantly), you probably need to add calls to it to your application.

**Compatibility note:** In 32-bit LispWorks version 5.1 and earlier, the documented way to collect generation 2 is to call `(mark-and-sweep 2)`. `(gc-generation t)` does what `(mark-and-sweep 2)` does, plus some additional operations that improve the performance of allocation. It also has the advantage that it is the same call that is used in 64-bit LispWorks. We recommend always using `gc-generation`.

To decide when to call `gc-generation`, you need to consider the following:

1. You need to prevent excessive growth of the process.
2. You want to avoid calling `gc-generation` when the application needs to respond quickly.
3. The call will be more effective if it is done between chunks of work than in the middle of a chunk of work.

We now discuss these considerations in detail:

1. You can follow the overall size of the process by looking at the output of `(room nil)`, or programmatically by using the result of `room-values`. The definition of "excessive growth" depends on the machine that you are running on and what the server actually does. Normally you want to avoid the need for paging, so you should try to keep the size of the image below the size of real memory that it can use. For 32-bit LispWorks on modern machines that have a lot of memory, the limit will be the amount of address space the machine has. In addition, garbage collecting a larger image takes more time. In a typical 32-bit application, 100-200 MB would be the target, though it can be larger. In a 64-bit application the limit is the size of the real memory.
2. `(gc-generation t)` can take a significant amount of time. 32-bit LispWorks on a modern machine can collect 100-200 MB in less than a second if it does not page. If it pages, or has a slower CPU, it takes more time. The 64-bit GC is generally faster and better, as long as it does not page, but since you normally deal with much more data in 64-bit images, there may be significant delays in 64-bit LispWorks. If such delays are a problem for your application, you should try to call `gc-generation` at times when it is less of a problem. Use `time` to find out how long `gc-generation` takes in various situations.
3. If you can identify places where there are no active chunks of work, you can try to place calls to `gc-generation` in these places. For servers, this is likely to be much less important than the two considerations above, but for an application that computes results using large amounts of data, this may be a significant consideration.

In 32-bit LispWorks, by default, generation 2 (which is the "blocking generation") is not collected automatically, because such collection may take a

significant amount of time, so most programmers need to control when it actually happens. You can change this by using `collect-generation-2`, but usually you need better control, and do a collection of generation 2 when it is appropriate. Therefore if your application generates long-lived data, you need to add calls to `gc-generation`.

Even if you find that your application does not generate long-lived data (that is, generation 2 does not grow), it is probably a good idea to keep checking, in case some circumstances do cause it to generate long-lived data.

In 64-bit LispWorks by default generation 3 (the "blocking generation") is collected automatically, so there is a good chance that you do not have to do anything. However, you may want to call `gc-generation` explicitly when you know it is a good time to do it. You may also want to block automatic calls if they take too long: use `set-blocking-gen-num` to do that. If generation 3 becomes very big (Gigabytes), you may also consider using `marking-gc` instead of `gc-generation`.

Once you set up `gc-generation` calls, you may still see the image growing even though the allocation does not grow that much. That is normally the result of fragmentation. In 32-bit LispWorks you can use `check-fragmentation` to check for fragmentation, and `try-move-in-generation` to prevent it if needed. See "Controlling Fragmentation" on page 144 for a discussion.

In 64-bit LispWorks you have a problem with fragmentation only if you use `marking-gc`. `marking-gc` has keyword arguments that can be used to reduce fragmentation, and there is a good chance that using these will be enough to avoid serious fragmentation. `gc-generation` can be used occasionally to eliminate all fragmentation. Check for fragmentation by using `gen-num-segments-fragmentation-state`.

#### 11.2.4 Permanent data

Permanently-living data will typically be the actual code of the application, and maybe also data that never goes away.

Because the data never goes away, it is best to put it outside normal garbage collection, which means promoting it to the highest generation. This is done by `clean-down`, which is called automatically (by default) when saving an image (whether by `save-image` or `deliver`). In most cases that is the right

time to do it, so normally you do not need to call `clean-down` explicitly. In some situations you may want to call it yourself, and sometimes you want to avoid the call when saving an image with a lot of non-permanent data. To control the automatic call, see `save-image` and `deliver`.

There are several things that need to be considered when using `clean-down`:

1. If the permanent data is only a small amount compared to the long-lived data, it is not obvious that `clean-down` is needed, specially if you use a saved (or delivered) image where the code and maybe some data was already promoted.
2. `clean-down` promotes all the data that is live (that is, pointed to from some other live object) in the image when it is called. If the image contains data that is live, but later becomes garbage, it will be promoted and hence not collected until another call to `clean-down`, which will make the image unnecessarily larger. Since this data is not being accessed, the effect on performance is small, but if there is a lot of it the effect may be significant.
3. `clean-down` needs extra memory to operate, especially in 64-bit LispWorks. For very large 64-bit LispWorks images `clean-down` may fail due to running out of swap memory.
4. `clean-down` takes a significant amount of time. If it does not cause paging, it should take seconds, but if it needs to page it may take much longer. You therefore should avoid calling it when you need the application to respond reasonably quickly.

## 11.3 Memory Management in 32-bit LispWorks

This section describes the garbage collector (GC) in 32-bit LispWorks 7.1.

In LispWorks for UNIX and LispWorks for Macintosh, the implementation is not significantly different to that in LispWorks 4.x, LispWorks 5.x or LispWorks 6.x.

In LispWorks for Windows and LispWorks for Linux, the implementation has changed since LispWorks 4.x and you may notice performance improvements relative to those versions.

### 11.3.1 Generations

In memory, a generation consists of a chain of segments. Each segment is a contiguous block of memory, beginning with a header and followed by the allocation area.

The first generation normally consists of two segments: the first segment is relatively small, and is where most of the allocation takes place. The second segment is called the big-chunk area, and is used for allocating large objects and when overflow occurs (see below for a discussion of overflow).

The second generation (generation 1) is an intermediate generation, for objects that have been promoted from generation 0 (typically for objects that live for some minutes).

Long-lived objects are eventually promoted to generation 2. Note that generation 2 is not scanned automatically. Therefore these objects will not be reclaimed (even if they are not referenced) until an explicit call to a GC function (for example `gc-generation` on `t`, or `clean-down`) or when the image is saved. Normally, objects are not promoted from generation 2 to generation 3, except when the image is saved.

Generation 3 normally contains only objects that existed at startup time, that is those were saved in the image. Normally it is not scanned at all, except when an image is saved.

Note that the division between the generations is a result of the promotion mechanism, and is not a property of a piece of code itself. A piece of system software code that is loaded in the system (for example, a patch) is treated the same as any other code. The garbage collection code is explicitly loaded in the static area using the function `switch-static-allocation`.

### 11.3.2 Allocation of objects

Normal allocation is done from a buffer, called the small objects buffer. The GC maintains a pointer to the beginning and end of the buffer, and allocates from it by moving one of the boundaries. When the buffer becomes too small the GC finds another free block and makes that the buffer.

In non-SMP LispWorks there is only one global small objects buffer. In SMP LispWorks, each process may have its own "local" small objects buffer (in

addition to the global one). The system decides dynamically which process should have a local buffer and which not. In general processes that do any significant amount of work have a local buffer, and most of their allocation would be from local buffers.

When there is an overflow the small object buffer is allocated in the big-chunk area, and then a bigger buffer is allocated (see below).

### 11.3.2.1 Allocation of static objects

Objects that cannot be moved are allocated in special segments, called static segments. These can be in any generation, but are in generation 2 by default.

Such objects include:

- Code that must not move during garbage collection, in particular the code and data of the GC itself
- Arrays created by `make-array` with `allocation :static`. This is the preferred way to allocate a static array.
- Objects allocated explicitly in the static area, by `in-static-area` or by use of `switch-static-allocation`.
- Foreign code loaded from a non-shared library via `link-load:read-foreign-modules`. This applies to LispWorks for SPARC Solaris only.

Because static objects are not allowed to move, the static segments are not allowed to move. This implies that if there is a static segment in a high address the image size cannot be reduced below this size. Applications that use a lot of static area normally allocate additional static segments, and thus grow without being able to shrink again. This can be prevented by enlarging the initial static segment, which is in a low address. Use the function `enlarge-static` to increase the size of the initial static segment. (Use `(room t)` to find its current size.)

### 11.3.2.2 Allocation in different generations

Objects that are known to have long life can be allocated directly in a higher generation, by using `allocation-in-gen-num` and `set-default-generation`. Note that both these functions have a global effect, that is any object

allocated after a call to `set-default-generation` or within the body of `allocation-in-gen-num` is allocated in the specified generation, unless it is explicitly allocated in a different generation. Therefore careless use of these functions may lead to allocation of ephemeral garbage in high generations, which is very inefficient. Conversely, if a long-lasting object is allocated to a low generation, it has to survive several garbage collections before being automatically promoted to the next generation.

The best way to control the allocation generation for an array is to call `make-array` with `allocation :long-lived` or a number.

See also “Allocation of interned symbols and packages” on page 164 and “Allocation of stacks” on page 164.

### 11.3.3 GC operations

Mark and sweep is the basic operation of reclaiming memory, and it is done in two stages:

<i>Mark</i>	All objects that are alive in the generation being garbage collected and in younger generations are marked as alive. (Alive means pointed to by some other live object.)
<i>Sweep</i>	All unmarked objects in the generations being garbage collected are added to the free blocks, and all marked objects are unmarked.

A mark and sweep operation is always on all the generations from 0 to a specific number.

A mark and sweep operation can be caused explicitly by calling `gc-generation`.

Promotion is the process of moving objects from one generation to the next generation. An object is marked for promotion after surviving a specific number of mark and sweep operations, but may be promoted before that. The number of survivals is specific to each segment.

Promotion does not free objects.

### 11.3.4 Garbage collection strategy

When the GC runs out of memory, it has to find more memory. Normally (that is, when allocating in generation 0) the first operation is a mark and sweep. Before performing the mark and sweep, the GC compares the amount of memory allocated since the previous mark and sweep with the `:minimum-for-sweep` value, which is set by `set-gc-parameters`. If the amount allocated is less than `:minimum-for-sweep` the GC does not do a mark and sweep, but causes an overflow (described below). This prevents an excessive number of mark and sweep operations in periods when the program allocates a large amount of data which stays alive.

If more than `:minimum-for-sweep` has been allocated, a mark and sweep operation takes place. After this operation the GC checks that the segment it was trying to allocate to has more free space than the minimum free space for this segment. If the remaining free space is less than `minimum-free-space`, the GC tries to create more free space by promoting objects from the segment.

Before promoting, the GC performs two checks. First, it checks that there are enough objects marked for promotion to justify a promotion operation. The minimum free space for a segment is set by `set-minimum-free-space`, and can be shown by `(room t)`.

Second, the GC checks that there is enough free space in the next generation to accommodate the promoted objects. If there is insufficient space, the GC tries to free some, either by a mark and sweep on the next generation, promoting the next generation, or by enlarging the generation.

The minimum amount of space for promotion is the value `minimum-for-promote`, which is set by `set-gc-parameters`.

If there is insufficient space, and there are not enough objects marked for promotion, the GC increases the size of the image, by overflow, as described below.

On Motif only, note that the GC monitor window does not indicate a mark and sweep of generation 0, as this operation takes a small amount of time (it would take longer to change the display of the window). The GC monitor window appears only in the Motif IDE.

### 11.3.5 Memory layout

#### 11.3.5.1 Linux

On Linux, the default initial heap is mapped at address `#x20000000` (0.5 GB). LispWorks then tries to locate the location of dynamic libraries, and marks a region around these libraries that should not be used (by default 64 MB from the bottom). In most cases this suffices to avoid clashes.

Problems can arise if the memory at `#x20000000` or above is already used by another part of the software. If that memory gets used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address, as described in “Startup relocation of 32-bit LispWorks” on page 460.

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by supplying *ReserveSize*.

The location of dynamic libraries differs between Linux configurations, and that needs to be taken into account. For most cases, including the cases where the libraries are mapped at `#x40000000` or somewhere above `#x28000000`, the mechanism for detecting libraries works and no action is required.

In principle LispWorks (32-bit) for Linux can grow up to some distance below `#xBF000000` (almost 2.5 GB), though this depends on the OS kernel allowing this size.

**Note:** In LispWorks 5.0 and previous, we told some customers to relocate above the libraries, for example at `#x50000000` or `#x48000000`, but this should not be needed in LispWorks 7.1.

#### 11.3.5.2 FreeBSD

By default, LispWorks is mapped at `#x30000000`.

Problems may arise if something uses memory above `#x30000000`. If this memory is used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address, as described in “Startup relocation of 32-bit LispWorks” on page 460.

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by using *ReserveSize*.

Normally the dynamic libraries are mapped at #x28000000, and therefore LispWorks can grow without a problem.

In principle LispWorks can grow up to some distance below #xc0000000 (almost 2.25 GB), though this depends on the OS kernel allowing this size and how many threads you have running.

### 11.3.5.3 x86/x64 Solaris

The default initial heap is mapped at address #x10000000 (0.25 GB).

LispWorks then tries to locate the location of dynamic libraries, and marks a region around these libraries that should not be used (by default 64 MB from the bottom). In most cases this suffices to avoid clashes.

Problems can arise if the memory at #x10000000 or above is already used by another part of the software. If that memory gets used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address, as described in “Startup relocation of 32-bit LispWorks” on page 460

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by supplying *ReserveSize*.

### 11.3.5.4 Windows and Macintosh

LispWorks (32-bit) for Windows and LispWorks (32-bit) for Macintosh both map by default at #x20000000. Since these platforms support reservation, normally you will not need to do anything special about this.

Problems may however arise if LispWorks operates in conjunction with non-relocatable software which insists on using addresses at #x20000000 or some distance above, in which case you will need to relocate LispWorks, as described in “Startup relocation of 32-bit LispWorks” on page 460.

LispWorks (32-bit) for Windows can in principle grow up to some distance below #x80000000 (almost 1.5 GB) but there is always the possibility that

some DLL will be mapped in this region. On startup, it reserves 0.5 GB above its location, so that much is guaranteed.

LispWorks (32-bit) for Macintosh can grow to around 2.7 GB. You can relocate it only on the Intel architecture.

### 11.3.5.5 AIX

The image is mapped at `#x31000000`.

The 16 MB (= `#x1000000`) above `#x30000000` allows it to grow down a little, which is used for static objects. In most cases it does not use this memory. The heap can grow up from `#x31000000` to `#xd0000000`, where the libraries are mapped.

LispWorks also maps some memory at `#xe0000000`, which is a read-only area containing code and some strings.

Foreign data (malloc and stacks) is in the normal AIX place, the 256 MB between `#x20000000` and `#x30000000`.

The heap is relocatable as described in “Startup relocation of 32-bit Lisp-Works” on page 460. However, to actually allow a larger area for foreign data, you also need to enable large address-space as far as AIX is concerned. This can done either at the time LispWorks is invoked by the environment variable `LDR_CNTRL` with `maxdata`, or statically on the LispWorks executable by using `ldedit` with `-bmaxdata`. For details see the entry for "Large program Support" in the AIX documentation (search for "Large program Support" at [www.ibm.com](http://www.ibm.com)).

When relocating it generally advisable to leave several megabytes between the heap and the top of the foreign data, in case LispWorks needs more static area. However, this is not essential, because in most of cases LispWorks will not need it, and it can allocate static areas higher.

### 11.3.6 Approaching the memory limit

If your program allocates a lot you may reach the limit of memory that Lisp-Works can use. The limit depends on the architecture as described in “Memory layout” on page 140.

When LispWorks actually reaches the limit it will fail to communicate with the user due to allocation errors. To avoid this situation, LispWorks informs the user earlier that it is approaching the limit of memory. It first checks whether you set the approaching memory callback (by `set-approaching-memory-limit-callback`), and if there is a callback calls it. If there is no callback or the callback returns, LispWorks signals an error of type `approaching-memory-limit` (which is a subclass of `c1:storage-condition`).

The function `memory-growth-margin` can be used to see how much LispWorks "believes" that it can grow.

The callback can be used to effectively ignore the condition, but this is a bad idea in general, because it will probably lead to an error later when LispWorks actually reaches the limit, and then it may crash in a bad way. To be safe, the callback should either cleanup and exit, or free a substantial amount of memory. You can reasonably continue only if a crash is not going to cause a serious damage.

### 11.3.7 Overflow

If the amount allocated from the previous mark and sweep operation is less than `:minimum-for-sweep`, the GC does not perform a mark and sweep. Instead it allocates a small-objects buffer in the big-chunk area (the second segment in the first generation). The minimum and maximum sizes of this buffer are specified by `:minimum-overflow` and `:maximum-overflow`, which can be set by `set-gc-parameters`. If the GC fails to find a buffer of this size, it looks for a smaller buffer, and if that fails it enlarges the big-chunk area (and the process size) by the amount needed to allocate a buffer of the size of the currently allocated area in generation 0, up to a maximum amount specified by `:maximum-overflow`.

### 11.3.8 Behavior of generation 1

When objects are promoted from generation 0 to 1, and there is not enough space in generation 1, the GC tries to free space in generation 1. The first step is to check whether sufficient space can be freed by promoting the objects marked for promotion. If this is the case the GC promotes these objects from generation 1 to generation 2. (In practice, this rarely happens.) If this check fails the GC marks and sweeps generation 1. If not enough space is freed by

this mark and sweep, than either all the objects in generation 1 are promoted, or generation 1 is expanded. This is controlled by `expand-generation-1`, which specifies whether expansion or promotion takes place.

If generation 1 is expanded, the amount it tries to expand by is the value `:new-generation-size` (set by `set-gc-parameters`) in words (that is, multiples of 4 bytes), or the amount of free space needed, whichever is bigger. If `:new-generation-size` is 0, it is not expanded. In this case part of the objects marked for promotion are not promoted.

### 11.3.9 Behavior of generation 2

Normally generation 2 is not garbage collected. If the system runs out of space in this generation, it expands it, using the value of `:new-generation-size` multiplied by two. Garbage collection of generation 2 can be caused by calling the function `collect-generation-2` with appropriate argument.

### 11.3.10 Forcing expansion

If you know that a given generation will need to grow, you can save the GC the work by calling `enlarge-generation` to expand the generation in advance.

### 11.3.11 Controlling Fragmentation

Some applications periodically free (that is, stop using) a substantial amount of data that lived for long enough to reach generation 2 (use `room` or `room-values` and `generation-number` to follow the behavior of objects). In this case, `gc-generation` should be called on generation 2, to collect these data and re-use the memory. Repeated cycles like this may cause fragmentation, which will slow down promotion into generation 2. This manifests itself in significant pauses, typically of a few seconds. `try-move-in-generation` or `try-compact-in-generation` can be used to reduce the fragmentation, and hence to reduce the pauses. Because these functions themselves take some time, they should be called when such a pause is acceptable.

'Moving' a segment means moving objects out of the segment to another segment, leaving the segment empty. This reduces the fragmentation in the generation, and it is normally much faster than compact. Therefore in almost all

cases, `try-move-in-generation` is better than `try-compact-in-generation`.

The actual decision to use these functions will be typically based on the results of `check-fragmentation`. For example, the following function checks whether there is more than 10 MB free area in generation 2 in blocks of 4096 bytes or larger (`tlb`, third return value of `check-fragmentation`). If there is not, and the free area in generation 2 (`tf`) is more than four times the free area in large blocks, it calls `try-move-in-generation`. Because `try-move-in-generation` gets a *time-threshold* of 0, it returns after moving at most one segment. (It will not move any segments if none of them looks fragmented.)

```
(defun call-memory-functions()
  (gc-generation t)           ; first collect all dead objects
  (multiple-value-bind (tf tsb tlb)
    (check-fragmentation 2) ; check the fragmentation
    (when (and (> 10000000 tlb)
               (> (ash tf -2) tlb))
      (try-move-in-generation 2 0))))
```

A function such as this can be called at times when a pause of a few seconds is acceptable, and it will keep the memory of generation 2 less fragmented.

It is not possible to give definitive guidance here on how to use `try-move-in-generation` or `try-compact-in-generation`, because it depends on the way the application uses memory. In general, these functions will always improve the behavior of the application. Therefore the main problem is to identify points in the execution of the application where they can be called without causing unacceptably long pauses.

### 11.3.12 Summary of garbage collection symbols

The remainder of this chapter summarizes which functions are useful in which circumstances. See also “Common Memory Management Features” on page 163. For full details of these functions, see their reference entries.

#### 11.3.12.1 Determining memory usage

To determine memory usage (useful when benchmarking), use the functions `room`, `total-allocation` and `find-object-size`. The function `room-values` is suitable for programmatic use: it returns the values that `room` prints.

In 32-bit LispWorks, `memory-growth-margin` returns the amount by which the Lisp heap can grow, if `set-maximum-memory` has been called.

### 11.3.12.2 Allocating in specific generations

Arrays can be allocated static or in a higher generation using the *allocation* argument in `make-array`.

To control the allocation of other objects to generations, use `allocation-in-gen-num`, `get-default-generation`, `set-default-generation` and `*symbol-alloc-gen-num*`.

### 11.3.12.3 Controlling a specific generation

To control the behavior of a specific generation, use `clean-generation-0`, `collect-generation-2`, `collect-highest-generation`, `expand-generation-1` and `set-minimum-free-space`.

### 11.3.12.4 Controlling the garbage collector

The functions that are most likely to be useful for controlling the GC are `room`, `check-fragmentation`, `gc-generation` and `try-move-in-generation`.

Other potentially useful functions and macros are `avoid-gc`, `get-gc-parameters`, `gc-if-needed`, `enlarge-generation`, `normal-gc`, `set-gc-parameters`, `with-heavy-allocation` and `try-compact-in-generation`.

## 11.4 Memory Management in 64-bit LispWorks

This section describes the garbage collector (GC) in 64-bit LispWorks.

### 11.4.1 General organization of memory

The memory in 64-bit LispWorks is arranged in segments, which belong to generations. Unlike 32-bit LispWorks, segments are sparsely allocated in memory, that is they are not contiguous.

Each segment has an allocation type, which defines the type of objects that the segment contains. The system creates and destroys segments as needed. A generation may or may not contain a segment for a specific allocation type,

and a generation may contain more than one segment for any particular allocation type. Segments may change in size.

You can see the allocation for each allocation type in the output of:

```
(room)
```

Additionally you can see the segments of each generation in the output of:

```
(room t)
```

After the total allocation in each generation, this prints the allocation type for each segment followed by the hexadecimal address range for allocating objects.

You can also use

```
(room :full)
```

which does not produce segments information, but prints allocated amounts by allocation types.

### 11.4.2 Segments and Allocation Types

Some GC interface functions take an allocation type as an argument, which is one of the keywords below. There are two categories of allocation type.

The main allocation types, which can be used as the *what* argument to the function `apply-with-allocation-in-gen-num`, are:

<code>:cons</code>	The segment contains only conses.
<code>:symbol</code>	The segment contains only symbols (and does not include symbol names or any of the other properties of symbols).
<code>:function</code>	The segment contains only function objects.
<code>:non-pointer</code>	The segment contains only objects that do not contain pointers (strings, specialized numeric arrays, double-floats).

**:other** The segment contain other objects, that is any object that contain pointers, and is not a symbol, cons or a function.

The derived allocation types are:

**:mixed** The segment contains a mixture of **:other**, **:function** and **:symbol**, but not **:cons** or **:non-pointer**.

**:cons-static**

The segment contains cons objects that are static.

**:non-pointer-static**

The segment contains objects that do not contain pointers and are static (currently stacks are also allocated in these segments).

**:mixed-static** The segment contains a mixture like **:mixed**, but static.

**:weak** The segment contains weak objects (arrays, and internals of weak hash tables).

**:other-big** The segment contains a single very large simple vector. The vector is static.

**:non-pointer-big**

The segment contains a single very large non-pointer object (a string or a specialized numeric array). The vector is static.

Segments of allocation type **:other-big** or **:non-pointer-big** can be as large as required to hold their object.

For all other allocation types, the size of each single segment is restricted. The implementation limit is currently 256 MB, and you can specify a smaller limit using **set-maximum-segment-size**.

### 11.4.3 Garbage Collection Operations

In 64-bit LispWorks there are two methods of garbage collection: *copy* (the default for all non-static objects) and *mark and sweep* (also referred to simply as *mark*) for static objects and under user control.

The two methods can be mixed within the same garbage collection operation and generation, but a segment is collected using only one of mark or copy in a given operation.

When a segment is collected using the copying method, the objects within it can either be copied to another segment in the same generation or can be copied to a segment in a higher generation. The latter case is called promotion.

The automatic garbage collection copies with promotion until the objects reach the blocking generation, which is collected in a specific way as described in “Generation Management” on page 149.

#### 11.4.4 Generation Management

In general, higher generations contain objects that live longer and are therefore much less likely to die. Each garbage collection only collects the generations up to some number, and never reclaims the objects in higher generations.

Objects move between generations by being promoted. For most allocation types, this means that the GC copies the objects from a segment in one generation to a segment in a higher generation. For allocation types `:other-big` and `:non-pointer-big`, the objects are not actually copied when they are promoted; but instead the whole segment is re-attached to the higher generation. The automatic garbage collection promotes objects until they reach the blocking generation.

In the default configuration, there are 8 generations, numbered from 0 to 7. Generation 7 is used to keep objects that survived saving the image. Generations 4, 5 and 6 are not used. Generation 3 is the blocking generation, where long-lived objects accumulate. Generations 0, 1, and 2 are ephemeral, and objects that survive a garbage collection in each of these generations are promoted to the next generation.

#### 11.4.5 Tuning the garbage collector

The GC settings are tuned for typical cases, so in general you do not need to change them. If you are considering tuning the GC, contact Lisp Support.

The main tools for seeing how the GC behaves are the macro `extended-time` and periodical calls to `room`.

In the output of `(room)` (or the more verbose `(room t)`), the allocation in each generation is presented according to the allocation type, which may be useful to decide on possible tuning.

`(extended-time forms)` outputs the time spent in garbage collection, whether automatic or called explicitly. The time is shown according to the maximum generation number that was collected and to whether it was a standard garbage collection (automatic and calls to `gc-generation`) or a marking garbage collection (calls to `marking-gc`).

In addition to `room` and `extended-time`, there are also the functions `count-gen-num-allocation`, `gen-num-segments-fragmentation-state`, and `set-automatic-gc-callback`. These function can be used to collect information about automatic garbage collection operations.

The profiler can also help determine whether the settings can be improved for your application. See Chapter 12, “The Profiler” for details of that.

#### 11.4.5.1 Interface for tuning the GC

The main interfaces are those which control the blocking generation.

For generations lower than the blocking generation, objects that survive are promoted, and the system does not automatically promote objects to higher generations. Thus if the application generates long-lived objects, they will accumulate in the blocking generation.

The behavior when the blocking generation grows is controlled by `set-blocking-gen-num` and `set-gen-num-gc-threshold`. It may also be useful to set the maximum segment size with `set-maximum-segment-size`.

Explicit garbage collection can be done by calling `gc-generation` and `marking-gc`. Since repeated use of `marking-gc` will cause a lot of fragmentation, the arguments `what-to-copy` and `max-size-to-copy` can be used to specify that part of the data should be collected by copying.

`gc-generation` can also be used to promote objects to a higher generation than the blocking generation.

It is normally less important to tune the ephemeral segments, that is the segments below the blocking generation. Functions that may be useful include

`set-default-segment-size`, `set-spare-keeping-policy` and `set-delay-promotion`.

## 11.5 The Mobile GC

The Mobile GC is a 64-bit GC that is written to run on 64-bit iOS (in the future it may be used on other platforms, for example 64-bit Android). When Lisp-Works is delivered for 64-bit iOS, the "saved image" (the code in the object file that delivery creates) switches automatically to use the Mobile GC. Thus you are always using the Mobile GC when running on 64-bit iOS, and you are not required to do anything about it.

The default parameters of the Mobile GC are intended to be useful for most applications and in many cases you do not need to do anything to tune the Mobile GC.

### 11.5.1 Mobile GC changes to common functions and macros

This section describes changes to the behavior of GC-related functions and macros when using the Mobile GC compared to the ordinary 64-bit GC. For most applications, `room`, and maybe `gc-generation`, are the only interesting functions. Specific functions for the Mobile GC are not discussed in this section.

#### mobile-gc-p

Returns true when running the Mobile GC.

#### room

The output of `room` is different for the Mobile GC. The last line (and the entire output of `(room nil)`) is the same, but the more detailed output is different. Without any argument, or if the argument is `:default`, Lisp-Works outputs the allocated and free sizes according to these types:

Cons            `cons` object only.

Other            All other objects, except static objects and large objects (> 1 MB).

Static	Static objects.
Large	Large objects (> 1 MB). Note: this threshold may change in the future, but it is fixed in the current version.

The Cons and Other segments are divided according to their generation and there may also some permanent segments (as a result of a call to `make-current-allocation-permanent`, `make-object-permanent` or `make-permanent-simple-vector`).

In addition, LispWorks also holds some reserved segments that are used during GC, and `room` prints the size of these too.

The output of `(room t)` also includes the segments for each type. For each segment, it prints the start and end addresses (in hex), the allocated area, and whether there is a free "hole" in the middle of it. For the Large and Static segments, it also prints the generation number of each segment. Permanent Static and Large segments have generation number 3.

See “Mobile GC technical details” on page 154 for more technical details.

### gc-generation

When the `gen-num` argument is a number, it must be 0, 1 or 2. The value `t` (and `:blocking-gen-num`) is interpreted as 2.

Generation 0 is always promoted, but the `:promote` keyword affects generation 1 and, if non-nil, promotes even if promotion was blocked by `set-promote-generation-1`.

The keyword `:coalesce` is interpreted as in the ordinary 64-bit GC. The keyword `:block` is ignored.

### marking-gc

Calls `gc-generation` with the `gen-num` argument. It is not useful in the Mobile GC.

### clean-down

Performs the same GC as `(gc-generation t)`.

**reduce-memory**

The *full* argument can be also be :**aggressive**, 0 1 or 2.

**count-gen-num-allocation**

The *gen-num* argument can be 0, 1, 2 or 3 (3 means permanent).

**in-static-area**

This does not affect allocation of conses (which are never static in the Mobile GC).

**apply-with-allocation-in-gen-num**

The *gen-num* argument must be 0, 1 or 2.

**sweep-all-objects**

Does not sweep **cons** objects in the Mobile GC.

**sweep-gen-num-objects**

Does not sweep **cons** objects in the Mobile GC.

The following functions do nothing in the Mobile GC, and the values that they return are not meaningful:

```
set-delay-promotion
set-maximum-segment-size
set-default-segment-size
set-gen-num-gc-threshold
set-blocking-gen-num
gen-num-segments-fragmentation-state
set-spare-keeping-policy
```

### 11.5.2 Mobile GC technical details

This section describes the Mobile GC in more detail. For most purposes, you do not need to understand the technical details of the Mobile GC, because it is used automatically and it should just work. You may want to know more if you want to fully understand the output of `room` (especially when called with T), and if you want to optimize memory usage (and maybe performance) of the application. In general, you should first use `time` or `extended-time` and `room` or `room-values` to understand the behavior of your application before trying to optimize it.

The ordinary 64-bit GC is "sparse", which means it leaves unused addresses between memory that it has allocated, and it also relies on being able to map memory at specific addresses. The result is a very efficient GC. However, on 64-bit iOS the range of addresses that is available (the address space) is very small compared to other 64-bit architectures (as determined experimentally because Apple do not document it), and also there is no documented interface for mapping at specific addresses. Therefore the ordinary 64-bit GC cannot work on 64-bit iOS, which is the reason for introducing the Mobile GC. The Mobile GC is less efficient than the ordinary 64-bit GC, but the only interface that it requires from the underlying OS for memory handling is `malloc` and `free`.

An additional issue specific to iOS is that iOS does not allow execution of machine code that is created dynamically, and the memory region where the code resides is read-only. Therefore the Mobile GC does not support compilation of code in memory at run time. Moreover, functions can contain data that can be modified so this needs to be separated from the code, which is not the case in the ordinary 64-bit memory model. To support this, the images that are used to deliver on iOS are different from the desktop images, though the difference is only in the memory layout of function objects, and from the programmer's point of view they behave the same. These images differ from the ordinary 64-bit images in that function objects and code are separated, and that function objects are allocated in the same segments as symbols (that is the allocation type `:symbol`). The code is allocated in objects with allocation type `:function`. See "Segments and Allocation Types" on page 147 for more details about allocation types. The names of these images and how to use them are described in "Delivering for iOS" on page 241.

The separation of code and use of the Mobile GC solves two different problems, which in principle could be solved separately. On 64-bit iOS, we have to solve both problems, and therefore the separation of code and the switch to the Mobile GC are done together.

### 11.5.2.1 Objects alive at delivery time

During delivery for 64-bit iOS, the code is separated out into its own block of memory (the "code block"). Then all of the other objects are put together in a block of memory, which is called the "data block". The data block is divided between non-pointer objects, weak objects and all other objects. The objects in the data block are never GCed, but the GC follows pointers from them to objects allocated at run time. Delivery creates an object file containing the code block and the data block, which is then linked with the rest of the app.

You cannot obtain a pointer to any object in the code block.

`generation-number` returns 3 for objects in the data block.

### 11.5.2.2 Objects allocated at run time

The Mobile GC has 4 different allocation types (note that these do not match the allocation types of the ordinary 64-bit GC described in “Segments and Allocation Types” on page 147):

Cons	<code>cons</code> objects
Static	Static objects
Large	Very large objects
Other	All other objects.

The Mobile GC does not allow allocation of static conses. Weak objects are allocated as Other or Large.

The different allocation types are allocated in separate segments, where a segment is a contiguous block of memory. Each allocation type has a variable number of segments, which are printed by `(room t)`. Each non-permanent segment belongs to a specific generation, which can be 0, 1 or 2. The permanent segments, which are created by `make-current-allocation-permanent`,

have generation number 3, even though there is not really a generation 3 (the GC does not collect them).

Like in the ordinary GC, allocation of static objects makes life more difficult for the GC (so it reduces the efficiency of LispWorks), and should be avoided.

Objects that are larger than a threshold (currently 1 MB, but this may change) are allocated in segments with the Large allocation type and are also static.

The vast majority of allocation happens in segments with the Cons and Other allocation types, which are together called "ordinary allocation". The segments for ordinary allocation are all of size 8 MB, including any overhead. For Cons segments, the overhead is larger because conses do not have headers.

The Mobile GC mixes marking and copying techniques. Copying has the advantage of eliminating fragmentation and is also more efficient for typical applications where most allocation is very short lived. On the other hand, it requires spare memory to be available during the GC. Marking creates fragmentation and is slower when most of the objects are freed immediately, but it does not require extra memory. Thus the Mobile GC tries to use copying when possible (that is when it can get enough memory from the operating system), and otherwise uses marking GC. The two methods may be mixed in the same GC operation.

For copying, LispWorks uses reserved segments, which it obtains from the operating system as needed. At the end of the GC, it returns any segments that are no longer needed to the operating system, except for some segments that it keeps in reserve. The amount of reserved memory that it keeps is dynamic, and by default grows as the amount of allocation grows. By default, as long as the amount of memory in ordinary segments is less than 48 MB, LispWorks tries to keep enough reserved segments to copy everything in generation 0 and 1 without asking the operating system for more memory. see [`set-reserved-memory-policy`](#) for details.

The copying GC might promote objects, which means copying them to the next generation. Generation 0 objects that are copied are always promoted (that is copied to generation 1). For Generation 1 objects, it is more complex:

For automatic GC:

`set-promote-generation-1` can be used to block any promotion from generation 1.

If promotion is not blocked (the default), then objects that have already survived a GC of generation 1 are promoted (copied to generation 2) and objects that are new to generation 1 remain in generation 1 (default setting) or are promoted depending on the setting by `set-split-promotion`.

For explicitly invoked GC by a call to `gc-generation`

The keywords `:promote` and `:coalesce` control whether objects from generation 1 are promoted or not. Generation 2 objects are always copied into generation 2.

Blocking promotion from generation 1 can be used to prevent GCs of generation 2, as discussed in “Preventing/reducing GC of generation 2” on page 159.

### 11.5.2.3 Special considerations for the Mobile GC

Because memory is more limited on mobile platforms, the Mobile GC is tuned to collect its highest generation (2) more often compared to the corresponding operation in the ordinary GC (which is a GC of generation 3). Such a GC may take enough time (in the order of a second) and be frequent enough to annoy users. If that happens then you need to try to tune your application, as described in “Preventing/reducing GC of generation 2” on page 159, and you can also try to reduce the amount that your application allocates.

Very large objects (> 1 MB) that do not contain pointers are handled especially efficiently by the Mobile GC. For example, if your program handles a million small strings of 10-15 characters, then you can save memory and maybe even speed up your program by storing them all in a very large string, and use fixnums to specify the bounds of the small strings within the large string instead of using pointers to the small strings. This saves memory and makes the reduces the work that the GC needs to do even if only half of the large string is actually used. Note also that when you finish with it, you can free a very large

object and return its memory to the operating system without doing a GC by calling `release-object-and-nullify`.

When a very large object that may contain pointers (for example a large `simple-vector`) is examined by the GC, it needs to go through all of those pointers. This is wasted work unless either it is long-lived and is rarely seen by the GC, or it is almost full of useful pointers, or if you make it permanent. Objects in general can be made permanent by `make-current-allocation-permanent`, which is discussed in “Preventing/reducing GC of generation 2” on page 159, but very large objects, which are allocated in their own segment, can also be made permanent individually by `make-object-permanent` or `make-permanent-simple-vector`. If most of the elements in a `simple-vector` are not pointers to objects that can be GCed, this substantially improves the performance of LispWorks.

Large objects which are allocated in their own segments can be explicitly freed (releasing the memory they use) by calling `release-object-and-nullify`. That releases the memory without a GC (so it is fast), and works on such objects even if they are permanent.

### 11.5.3 Tuning memory management in the Mobile GC

#### 11.5.3.1 Response to low memory

Mobile platforms typically inform applications when memory availability becomes low. On Android this is done by the `onTrimMemory` or `onLowMemory` methods and on iOS by the `didReceiveMemoryWarning` method. It is probably a good idea to respond to these methods, but it is not essential.

In your implementation of these methods, you should release any system resources that can be released without loss and also try to reduce the memory used by Lisp data. Since the GC sometimes temporarily requires more memory during an operation, it may be a bad idea to do a GC once you get the warning. The function `reduce-memory` is provided to reduce memory usage without requiring more memory temporarily. Note that `gc-generation` can do a much better job than `reduce-memory` in general, but it may require more memory temporarily.

Calling `reduce-memory` with argument `nil` (the default) just releases any reserved memory that LispWorks has kept. It is fast and probably always a good idea. However, with argument `nil`, `reduce-memory` does not perform any GC operation, which in principle could release more memory. Because a GC takes time, it is not obvious whether it worth the trouble.

Calling `reduce-memory` with 0 or 1 causes a GC of generation 0 or 1, which is probably fast enough (unless promotion of generation 1 is blocked and generation 1 grows), but will not typically release much memory.

Calling `reduce-memory` with 2 (or, equivalently, T), or even `:aggressive`, can release much more memory, but takes more time, depending on the size of generation 2. Unless it is likely to release a large amount, it is probably not worth it. Thus, unless you know that generation 2 contains a lot of dead objects, you should only call `reduce-memory` with `nil`, or maybe 0 or 1.

If you call `reduce-memory` with a non-nil argument, you should first clear any caches that you have kept, so their contents can be GCed.

To be able to reduce memory usage, `reduce-memory` needs reserved memory to perform a copying GC. Since `reduce-memory` never obtains more memory from the operating system, its effectiveness depends on the amount of reserved memory that it has when it is called. Moreover, any call to `reduce-memory` frees all of the reserved memory (once the GC has occurred if the argument is non-nil), so calling `reduce-memory` with non-nil shortly after a previous call with NIL is not going to be effective.

To see how much effect `reduce-memory` had on the memory, you can look at the output of `room` (last line with any argument you give it), or the result of `room-values`. To see how much time it takes, use the `time` macro or `get-internal-real-time`.

### 11.5.3.2 Preventing/reducing GC of generation 2

GC of generations 0 and 1 should normally be fast enough that you do not need to worry about them. GC of generation 2, however, typically takes enough time to be noticeable, and if generation 2 is large (> 100 MB) can take more than a second. Thus you normally want to avoid GC of generation 2.

In a "nicely behaved" application, which we believe is true for most applications, generation 2 never needs to be collected. This is based on the assumption that the application's memory usage is bounded and predictable.

tion that a nicely behaved application starts with some initialization that allocates long-lived objects, but then enters a "work" phase, where it allocates only short lived objects, which die before they reach generation 2.

Even if there is some "generation leak", that is objects being promoted from generation 1 to 2 that die not long afterwards, the leak may be slow enough that it is not a problem. For example, if your application "leaks" on average 1 kB each second, it would take close to 3 hours of operation to leak 10 MB, which is still too small to worry about (the default minimum size of generation 2 before a GC is 64 MB). So you can usually ignore this kind of leakage and hope that any occasional delay of a second or two after running the application for many hours is not too annoying for the user (though if it only a "generation leak", you can do better by blocking promotion). If you have a leakage of 100 kB per second, the delay would happen every few minutes, which may be too annoying.

To find if your applications leaks to generation 2, you should periodically log the size of either the whole application or of generation 2. The output of `room` is the most useful thing to log, but you can also use `room-values` or `count-gen-num-allocation`. If the application does leak to generation 2, you should determine if it is a real memory leak, which means that the application accumulates live objects, or just a generation leak, which means that objects live long enough to reach generation 2 and then die. To determine that, call `(gc-generation T)` (or, equivalently, `(clean-down)`), continue using the application for a while and then call it again. If the leak is just a "generation leak", then the size of generation 2 after `(gc-generation t)` should stay (more or less) the same. If it grows, then you have a real memory leak.

If your application is "nicely behaved", generation 2, and hence the whole application, will initially grow, typically by few 10's of megabytes, and then will stay more or less fixed. The size of the whole application will always fluctuate, because generation 0 and 1 fluctuate, but generation 2 should be stable or grow slowly. If this is the case, you probably do not need to do anything further to control memory usage.

If generation 2 does grow, LispWorks will occasionally do a GC of generation 2, which takes a noticeable time (maybe a few seconds if generation 2 is few 100's of megabytes). If the leak is a real memory leak, it will also cause the application to grow indefinitely.

If the leak is a real memory leak, then the GC cannot do anything about it. One possibility is to make the application run for a limited time, for example by monitoring the size and quitting when it reaches some threshold. If quitting and restarting is possible without much loss, that may be a good solution. Most of applications probably want to avoid that though, in which case you will need to figure out what keeps objects alive and fix it. The functions `sweep-all-objects`, `sweep-gen-num-objects` and `mobile-gc-sweep-objects` can be used to check what kind of objects have accumulated. However, whatever keeps the objects is something in your application, and you will have to find it.

If the leak is only a "generation leak", then there are several ways to deal with it:

- Block promotion from generation 1 to 2 by calling `set-promote-generation-1` with `nil`.

Once you have made this call, the automatic GC will never promote to generation 2 (explicit invocation of the GC ignores this setting). This is useful in situations where the "leaking" objects are live long enough to be promoted to generation 2, or the memory they use is small, so generation 1 does not grow too much. If there are many objects that live longer, then generation 1 will grow, and hence the GC of generation 1 will become slow. You should check if generation 1 grows, but it is probably OK if it remains at 20-30 megabytes allocated after a GC. You can try timing a GC of generation 1 by `(time (gc-generation 1))`.

Note that you can switch promotion on and off as needed, so if you can identify phases in your application when allocation is not long-lived and phases when some is long-lived, then you can switch promotion on and off as appropriate.

- Prevent GC in generation 2 by calling `set-generation-2-gc-options`. Once you have called `set-generation-2-gc-options` with `:minimal-size-for-gc t`, LispWorks will not automatically GC generation 2. It is then your responsibility to GC generation 2 at the appropriate time by calling `(gc-generation 2)`.

As above, one of the options is to never GC generation 2, and just quit when the application reaches some size. Otherwise, you will need to identify appropriate points in time to perform the GC.

In an interactive application, you can have a "cleanup" option somewhere that invokes the GC, so the user can invoke it. You probably also want some indicator when the application has grown and needs a "cleanup".

For an interactive application, it may be useful to do a GC when the application becomes backgrounded, but it is not obviously so. The method that is called by the operating system to indicate that the application has been backgrounded must return in a short time, so you probably need to invoke the GC from another thread. Also the operating system may not give much CPU to the application while it is in the background, and may even terminate background applications that take CPU. For example, the "App Programming Guide for iOS" says: "Apps that spend too much time executing in the background can be throttled back by the system or terminated." A GC of a 100-200 megabyte application should not take enough time to cause termination, but it depends both on the underlying system (hardware and OS) and the current state of it, so it is not that predictable. You certainly need to store anything that needs to be stored before doing a GC while in the background.

As long as memory is not constrained, the time it takes to GC generation 2 correlates to the amount alive after the GC rather than before the GC (because it uses copying, so does not touch dead objects). Therefore, if you have points in time in the execution when you know your application uses less memory then these are good points for doing a GC. That would be the case if your application builds a large data structure for a task (allocation of > 10 megabytes), and all this data becomes free when the task finishes. In this situation, it may be useful to perform a GC in the end of the task.

- Tuning the GC of generation 2 by `set-generation-2-gc-options`.

By calling `set-generation-2-gc-options` you can tune the frequency of GC of generation 2. You can either aim for infrequent GCs, which may be long but hopefully rare enough not to be too annoying, or aim for frequent GCs which are fast enough that they do not bother the user.

When the amount that is alive after a GC is almost always much less than the amount alive before, which is quite common, you can tell that to the GC by `set-expected-allocation-in-generation-2-after-`

`gc`. This can significantly improve how well the GC copes when it fails to get as much memory as it asks for from the operating system. See `set-expected-allocation-in-generation-2-after-gc` for details.

- Making the long-lived objects permanent by using `make-current-allocation-permanent`.

The function `make-current-allocation-permanent` causes all the currently allocated objects to be made permanent, which means that the GC will not scan or free them in future (but it will still follow pointers from them). That is useful in the typical situation where the application starts with some initialization that creates long-lived objects. Using `make-current-allocation-permanent` at the end of the initialization makes all these objects permanent, and therefore reduces the time for GC of generation 2. If new objects in generation 2 after initialization are only the result of "generation leak" then the effect on time can be quite large.

## 11.6 Common Memory Management Features

This section summarizes Memory Management functionality common to all LispWorks 7.1 implementations.

### 11.6.1 Timing the garbage collector

The macro `extended-time` is useful when timing the Garbage Collector (GC).

Use `start-gc-timing`, `stop-gc-timing` and `get-gc-timing` to time GC operations.

### 11.6.2 Reducing image size

To reduce the size of the whole image, use `clean-down`.

In 32-bit LispWorks, you can use `(clean-down)` or the less aggressive `(clean-down nil)` to reduce the image size when the image is much larger than the amount that is allocated. In 64-bit LispWorks there is no need to do that.

`(clean-down t)` promotes to generation 3 and tries to reduce the image size, while `(clean-down nil)` promotes only to generation 2 and does not reduce

the image size. Experience suggests that the latter is actually more useful in most circumstances.

In some circumstances it is important to avoid enlarging the size of the image even temporarily. The common situation is when the operating system signals low memory. In this situation you should use `reduce-memory` instead of `clean-down`.

### 11.6.3 Allocation of interned symbols and packages

Interned symbols (and their symbol names), and packages, are treated in a special way, because they are assumed to have a long life. They are allocated in the generation specified by the variable `*symbol-alloc-gen-num*`, which has the initial value 2 in 32-bit LispWorks and 3 in 64-bit LispWorks.

Symbols created with `make-symbol` or `gensym` start out in generation 0.

Symbols will be garbage collected if they are no longer accessible (regardless of property lists) but note that in 32-bit LispWorks, if the symbols are in generation 2 then you might need to invoke `gc-generation` explicitly to collect them in a timely manner.

### 11.6.4 Allocation of stacks

Stacks are allocated directly in generation 2 because they are relatively expensive to promote. Therefore creating many processes will cause generation 2 to grow, even if these processes are short-lived.

The variable `*default-stack-group-list-length*` controls the number of stacks that are cached for reuse. Increase its value if your application repeatedly makes and discards more than 10 processes.

### 11.6.5 Mapping across all objects

To call a function on all objects in the image, use `sweep-all-objects`.

### 11.6.6 Special actions

You may want to perform special actions when certain types of object are garbage collected, using the functions `add-special-free-action`, `flag-spe-`

`cial-free-action`, `flag-not-special-free-action` and `remove-special-free-action`.

For example, when an open file stream is garbage collected, the file descriptor must be closed. This operation is performed as a special action.

### 11.6.7 Garbage collection of foreign objects

Users of the Foreign Language Interface may want to specify the allocation of static arrays. The recommended way to do this is to call `make-array` with `:allocation :static`. See for example `:lisp-array` in the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

### 11.6.8 Freeing of objects by the GC

Weak arrays and weak hash tables can be used to allow the GC to free objects.

Relevant functions are `make-hash-table`, `set-hash-table-weak`, `set-array-weak`, `make-array` and `copy-to-weak-simple-vector`.

For a description of weak vectors see `set-array-weak`, page 1012.

### 11.6.9 Assisting the garbage collector

This section describes techniques that may improve the performance of your application by reducing the GC's workload.

#### 11.6.9.1 Breaking pointers from older objects

This is a technique that can be useful when older objects regularly point to newer objects in a lower generation. In such a case, when the lower generation (only) is collected these newer objects will be promoted even if the older objects are not live. All of these objects will not get collected until the higher generation is collected.

This is a general issue with generational garbage collection and, if it causes poor performance in your application, can be addressed along these lines. It is not necessarily a problem in every case where older objects point to newer objects.

For example, suppose you are popping items from a queue represented as a list of conses (or other structures), then you can set the "next" slot of each popped item to `nil`.

In the code below, if the `queue-head` cons is promoted to generation  $n$ , then all the other conses will also be promoted to generation  $n$  eventually, until generation  $n$  is collected. This happens even after calls to `pop-queue` have removed these conses from the queue.

```
(defstruct queue head tail)

(defun push-queue (item queue)
  (let ((new (cons item nil)))
    (if (queue-head queue)
        (setf (cdr (queue-tail queue)) new)
        (setf (queue-head queue) new))
    (setf (queue-tail queue) new)))

(defun pop-queue (queue)
  (pop (queue-head queue)))
```

The fix is to make `pop-queue` set the "next" slot (in this case the `cdr`) of the discarded `queue-head` cons to `nil`, so that it no longer points from an older object to a newer object. For example:

```
(defun pop-queue (queue)
  (when-let (head (queue-head queue))
    (setf (queue-head queue) (shiftf (cdr head) nil))
    (car head)))
```

# 12

---

## The Profiler

The LispWorks profiler provides a way of empirically monitoring execution characteristics of Lisp programs. The data obtained can help to improve the efficiency of a Lisp program by highlighting those procedures which are commonly used or particularly slow, and which would therefore benefit from optimization effort.

### 12.1 What the profiler does

With the profiler running, the Lisp process is interrupted regularly at a specified time interval until the profiler is turned off. Having halted the execution of the process the profiler scans the execution stack and records information about it, including the names of all functions found. A special note is made of which function is at the top of the stack. After profiling stops the profiler can present a report containing a call tree and/or a cumulative columnar report.

The columnar report shows aggregated information about each function as follows:

- The number of times the function was called.
- The number of times the function was found on the stack by the profiler, both in absolute terms and as a percentage of the total number of scans of the stack.

- The number of times the function was found on the top of the stack, both in absolute terms and as a percentage of the total number of scans of the stack.

The call tree shows name of a root function and a "tree" of callee functions below it. To the right of each function's name the number of times it was seen on the stack under a particular caller is shown, along with the percentage this represents of the total number of times the function was seen.

The call tree is more computationally expensive to record than the cumulative data. You can choose whether to record and output the call tree, as described in the next section.

## 12.2 Setting up the profiler

Before a profiling session can start, several parameters must be set, using the function `set-up-profiler`. If the profiler is invoked before any call to `set-up-profiler`, it calls `set-up-profiler` implicitly without any arguments. In many cases that is what you want anyway, and in these cases you do not need to call `set-up-profiler`, but in some cases you will want to change something.

There are four main areas to consider: the symbols to be profiled, the time interval between samples, the kind of profiling required, and the format of the output.

- By default, all fbound symbols in the image are monitored (and, if KnowledgeWorks is loaded, also all the forward chaining rules). This setting is useful in many cases, but in some cases you will want to see information only about some subset of the symbols, which will make it easier to read the output. Use the keywords `:packages` and `:symbols` (and `:kw-contexts` for KnowledgeWorks) to restrict the set of symbols that will be profiled.
- You might want to specify the time interval between interrupts. The resolution of this value is clearly dependent on the operating system. In most cases the default value, 10ms, is adequate. This number is important, because with these statistical methods of program profiling the accuracy of the results increases with the number of samples taken.

- On non-Windows systems the kind of profiling required may be set. This refers to what kind of time is monitored in order to determine when to interrupt the Lisp process. There are three possibilities for how the time interval is measured:
  - The time the Lisp process is actually executing plus the time that the system is executing on behalf of the process. This is called *profile time*.
  - Just the time that the process is actually executing. This is called *virtual time*.
  - The actual elapsed time, called *real time*.
- The output can be presented as a tree of calls seen and a columnar report (`style :tree`), or just the columnar report (`style :list`). You can restrict the data shown in several ways, helping you to focus on the slowest parts of your program.

## 12.3 Running the profiler

The profiler has two distinct modes. You can use both in the same session, but not at the same time.

To use either mode, you must first call `set-up-profiler` to load the profiler and set its parameters including the output format.

The macro `profile` simply profiles all processes while a body of code is run, as described in “Using the macro profile” on page 169. Start profiling this way if you don’t see a need to use the alternate mode.

Alternatively the functions `start-profiling`, `stop-profiling` and `set-process-profiling` offer programmatic control over when profiling occurs and which processes are profiled. This is described in “Programmatic control of profiling” on page 170.

The function `do-profiling` is a convenience function which allows you to profile multiple threads using `start-profiling` and `stop-profiling`.

### 12.3.1 Using the macro profile

To profile your Lisp forms enter:

```
(profile <forms>)
```

This evaluates the forms as an implicit `progn` and prints the results, according to the parameters established by `set-up-profiler`.

**Note:** you cannot use `profile` (or the graphical Profiler tool) after a call to `start-profiling` and before a call to `stop-profiling` with `print t`, because the two profiling modes are incompatible.

### 12.3.2 Programmatic control of profiling

Your program can control profiling. This is useful when you want to profile only a part of the program.

In your program, call `start-profiling` start collecting profiling information. Call `stop-profiling` with `print nil` to temporarily stop collecting, or call `stop-profiling` with `print t` to stop collecting and print the results. At any point you can call `set-process-profiling` to modify the set of processes for which profiling information is being (or will be) collected.

For example:

```
; ; start profiling, current process only
(start-profiling :processes :current)
(do-interesting-work)
; ; temporarily suspend profiling
(stop-profiling :print nil)
(do-uninteresting-work)
; ; resume profiling
(start-profiling :initialize nil)
(do-more-interesting-work)
; ; now, all processes are interesting
(set-process-profiling :set :all)
(do-some-more-interesting-work)
; ; stop profiling and print the results
(stop-profiling)
```

**Note:** you cannot call `start-profiling` inside the scope of the macro `profile` or while the graphical Profiler is profiling, because the two profiling modes are incompatible.

## 12.4 Profiler output

A typical report would be:

```

profile-stacks called 564 times

Call tree
Symbol          seen   (%)
 1: MOD          17 ( 3)
 2: FLOOR        5 ( 1)
 1: EQL          8 ( 1)
 1: >=           7 ( 1)
 2: REALP         2 ( 0)
 1: +             6 ( 1)
 1: LENGTH        4 ( 1)

Cumulative profile summary
Symbol      called  profile   (%)      top   (%)
MOD        1000000    17 ( 3)      8 ( 1)
EQL        2000117    8 ( 1)      8 ( 1)
>=         1000001    7 ( 1)      5 ( 1)
+          1000000    6 ( 1)      6 ( 1)
FLOOR      1000000    5 ( 1)      5 ( 1)
LENGTH     2000086    4 ( 1)      4 ( 1)
REALP      1000001    2 ( 0)      2 ( 0)

Top of stack not monitored 93% of the time

```

The first line means that Lisp was interrupted 564 times by the profiler.

The call tree shows that in 17 of these interrupts (3% of them) the profiler found the function `mod` on the stack, in 5 of these interrupts it found the function `floor` on the stack, and so on. Moreover, `floor` only appears under the `mod` branch of the tree, which means that each of these times `floor` was called by `mod`.

The cumulative profile summary also shows how many times each symbol was found on the stack. Moreover it shows that the function `mod` was called 1000000 times, the function `eql` was called 2000117 times, and so on. (Note: this information is not collected on Intel-based platforms by default.) In 17 of these interrupts it found the function `mod` on the stack, and on 8 of these occasions `mod` was on the top of the stack. You can deduce that 526 times the function on the top of the stack was none of those reported.

You can control sort order of the cumulative profile summary with `print-profile-list`.

### 12.4.1 Interpretation of profiling results

One important figure is the amount of time it was found on top of the stack in the cumulative profile summary. Just because a function is found on the stack does not mean that it uses up much processing time, but if it is found consistently on the top of the stack then it is likely that this function has a significant execution time. Another thing to check is that you expect the functions near to top of the call tree to take significant time.

It must be remembered that the numbers produced are from random samples and thus it is important to be careful in interpreting their meaning. The rate of sampling is always coarse in comparison to the function call rate and so it is possible for strange effects to occur and significant events to be missed. For example, “resonance” may occur when an event always occurs between regular sampling times, though in practice this does not appear to be a problem.

### 12.4.2 Displaying parts of the tree

Once profiling information has been recorded, either by `stop-profiling` or a normal exit from `profile`, it is possible to print specific parts of the information. The function `profiler-tree-from-function` prints a tree showing a specific function and the functions called inside it. The function `profiler-tree-to-function` prints a tree showing a specific function and its callers. This tree is inverted, which means that the children of a node are its callers, rather than callees as in the full tree and the tree printed by `profiler-tree-from-function`.

## 12.5 Profiling pitfalls

Profiling should only be attempted on compiled code. If it is done on interpreted code, the interpreter itself is profiled, and this distorts the results for the actual Lisp program.

Macros cannot be profiled as they are expanded during the compilation process. Similarly some Common Lisp functions may be present in the source code but not in the compiled code as they are transformed by the compiler. For example:

```
(member 'x '(x y z) :test #'eq)
```

is transformed to:

```
(memq 'x '(x y z))
```

by the compiler and therefore the function `member` is never called.

Recursive functions need special attention. A recursive function may well be found on the stack in more than one place during one interrupt. The profiler counts each occurrence of the function. Hence the total number of times a function is found on the stack may be much greater than the number of times the stack is examined.

Tail call optimization will prevent the calling function from being found on the stack after the call. You can disable tail call optimization by compiling code with optimize quality `debug 3`, but note that this might also affect the performance.

Care must be taken when profiling structure accessors. Structure accessors compile down into a call to a closure of which there is one for all structure setters and one for all structure getters. Therefore it is not possible to profile individual structure setters or getters by name.

It must be remembered that even though a function is found on the stack this does not mean that it is active or that it is contributing significantly to the execution time. However the function found on the top of the stack is by definition active, and thus this is the more important value.

It is quite possible that the amount of time the top symbol is monitored is significantly less than 100% despite the profiler being set to profile all the known functions of the application. This is because at the time of the interrupt an internal system function may well be on the top of the stack.

## 12.6 Profiling and garbage collection

The macro `extended-time` provides useful information on garbage collection activities.

The `gc` argument of `set-up-profiler` controls whether or not the system's memory management functions are profiled.

## 12.7 Profiler tree file format

The profiler tree file is produced by calling `save-current-profiler-tree`, or by using the **Save Profiler tree...** item from the **Profiler** menu on the Lisp-Works IDE.

The file contains lines of text encoded UTF-8, to allow it to contain any symbol name.

The first line is handled specially: it must contain the string "LispWorks Profiler Tree" (without the quotes), which confirms that the file is a profiler tree file. In addition, the text following the first colon in the first line, with leading and trailing spaces removed, is the name of the tree.

The remaining lines in the file are the data lines, except those starting with a semicolon which are ignored.

Each data line is divided to 6 fields by a | character. The first 5 fields are integers and the last field is an arbitrary sequence of characters (any character except newline). There must be no spaces between the fields.

Each line specifies a node in the tree, in this format:

***Depth | Count | Call-Count | Seen-Count | Top-Count | Name***

*Depth* specifies the depth of the node, from which its location in the tree is deduced. The node with depth 0 is the root. For other nodes, the parent of the node is the previous node in the file which has depth smaller by 1. The children of the node, are all following nodes with depth larger by 1, until the next node with a depth less than or equal to *Depth*. In other words, each node is followed by its children in depth-first order.

*Count* is the number of times that the function associated with the node was seen on the call stack within the same branch of the tree, that is with the same chain of callers and on the same process.

*Call-Count*, *Seen-Count*, *Top-Count* and *Name* are the *function-info* of the function associated with the node. Hence they are not specific to the node itself and if the function occurs more than once in the tree (which is common), then copies of the *function-info* will be present in each occurrence.

The fields of the *function-info* are:

<i>Call-Count</i>	The number of times that the function was called, if this is recorded. Note that the count is not recorded by default in SMP LispWorks, so it is 0.
<i>Seen-Count</i>	The number of times that the function was seen in all the branches of the tree.
<i>Top-Count</i>	The number of times that the function was seen at the top of the stack, that is it was actually executing.
<i>Name</i>	The name of the function. Note that some nodes do not correspond to actual functions, in which case the name will be a string (including the double quotes).

### 12.7.1 Parsing the file

Because the *function-info* fields of each node are repeated for each occurrence of the same function, it is useful to record function-info keyed on the Name. This allows you to associate nodes that are in different branches of the tree but represent the same function.

The name can be read using the Common Lisp reader, provided the currently interned symbols are the same as the interned symbols when the file was produced. Otherwise you may get an error if the package of a symbol does not exist, or if it was external but it is not external when reading. In many cases, just using the name as a string is probably good enough.

### 12.7.2 Viewing the file as text

While it is not possible to see the tree in the file, you can perform simple "queries" just by viewing it in a text editor, for example checking if a function appears anywhere in the tree, finding how often it was visible or getting an idea which function(s) mostly call it.

# Customization of LispWorks

This chapter gives examples of how to make changes to LispWorks to make it more suitable for use by you and your colleagues.

## 13.1 Introduction

### 13.1.1 Pre-loading code

You can save an image with changes pre-loaded. This is suitable for changes you want to share with other users of that image, and for code which takes some time to load. It cannot be used to alter settings which the system makes automatically on startup.

“Saving a LispWorks image” on page 179 describes how to do this.

### 13.1.2 Loading code at start up

You can also load changes each time you start LispWorks. This is suitable for code which loads quickly. For changes only you want to see, put the code in your personal initialization file. For changes to share with other users at your site, put the code in your site initialization file.

“Initialization files” on page 178 describes these initialization files.

### 13.1.3 Specific customizations

The remainder of this chapter describes some customizations, all of which can be saved in an image or placed in an initialization file, as needed. You can use both techniques: stable code including patches is saved in the image, while experimental or fast-loading code is loaded via the initialization file.

## 13.2 Configuration and initialization files

There are a number of files that contain configuration and initialization information:

### 13.2.1 Configuration files

- The LispWorks file `config/configure.lisp` contains many default configuration settings. You can create a customized copy of this file when you install LispWorks, as described in the *LispWorks Release Notes and Installation Guide*.
- The LispWorks file `config/key-binds.lisp` gives the default editor key bindings for Emacs emulation.
- The LispWorks file `config/mac-key-binds.lisp` gives the editor key bindings for Mac OS editor emulation, if supported on your platform.
- The LispWorks file `config/msw-key-binds.lisp` gives the editor key bindings for Microsoft Windows editor emulation, if supported on your platform.

### 13.2.2 Initialization files

- The LispWorks file `config/siteinit.lisp` is the default site initialization file. The distributed file loads any supplied patches.
- You may also have a personal initialization file which is loaded on startup. By default LispWorks looks for a file called `.lispworks` in your home directory, although you can change its name and location (see “Setting Preferences” in the *LispWorks IDE User Guide*).

The default location of your home directory varies on Unix systems, but it is typically something like `/home`. On Windows, the directory is constructed from the environment variables HOMEDRIVE and HOME-  
PATH. The directory itself has the same name as your user name, so if you log on as `john`, your home directory might be `/home/john` on Unix systems or something like `C:\users\john` on Windows 8.

A sample personal initialization file, the LispWorks file `config/a-dot-lispworks.lisp`, is supplied. You should create a customized copy of this file when you install LispWorks, as described in the *LispWorks Release Notes and Installation Guide*.

## 13.3 Saving a LispWorks image

There are two ways to save an image with changes pre-loaded.

- This section describes the traditional method, using a configuration file and `save-image` script.
- “Saved sessions” on page 182 describes how to save a session, which allows restoring your windowing environment as well as your Lisp objects.

### 13.3.1 The configuration file

First create a file `my-configuration.lisp` containing the settings you want in your saved image. You may want to change some of the pre-configured settings shown in `config/configure.lisp`, add customizations from the rest of this chapter, or load your application code.

### 13.3.2 The save-image script

Now create a `save-image` script which is a file `save-image.lisp` containing something like:

```
(in-package "CL-USER")
(load-all-patches)
(load #-mswindows "/tmp/my-configuration.lisp"
      #+mswindows "C:/temp/my-configuration.lisp")
#+:cocoa
(compile-file-if-needed
 (sys:example-file
  "configuration/macos-application-bundle")
 :load t)
(save-image
 #:cocoa
 (write-macos-application-bundle
  "/Applications/LispWorks 7.1 (32-bit)/My LispWorks.app")
 #:-cocoa "my-lispworks")
```

The script shown loads `my-configuration.lisp` from a temporary directory. You may need to modify this.

### 13.3.3 Save your new image

The simplest way to save your new image is to use the Application Builder tool in the LispWorks IDE. Start the Application Builder as described in the *LispWorks IDE User Guide*, enter the path of your `save-image` script in the **Build script:** pane, and press the **Build the application using the script** button.

Alternatively you can run LispWorks in a command interpreter and pass your `save-image` script in the command line as shown below.

- On Macintosh, run in Terminal.app:

```
mymac$ "/Applications/LispWorks 7.1 (32-bit)/LispWorks (32-
bit).app/Contents/MacOS/lispworks-7-1-0-x86-darwin" -build save-
image.lisp
```

Your new application bundle is saved in `/Applications/LispWorks 7.1 (32-bit)/My LispWorks.app`

- On Microsoft Windows, run in a MS-DOS window:

```
C:\temp\>"C:\Program Files\LispWorks\lispworks-7-1-0-x86-
win32.exe" -build save-image.lisp
```

Your new LispWorks image is saved in `C:\temp\my-lispworks.exe`.

- On Linux, run in a shell:

```
linux:/tmp$ lispworks-7-1-0-x86-linux -build save-image.lisp
```

Your new LispWorks image is saved in `/tmp/my-lispworks`.

For other platforms and for 64-bit LispWorks the image name varies from that shown, but the principle is the same.

### 13.3.4 Use your new image

Your new LispWorks image contains the settings you specified in `my-configuration.lisp` pre-loaded.

You can add further customizations on start up via the initialization files mentioned in “Initialization files” on page 178.

Note that your newly saved image runs itself, not a saved session.

### 13.3.5 Saving a non-GUI image with multiprocessing enabled

To create an image which does not start the LispWorks IDE automatically, make a `save-image` script, for example in `/tmp/resave.lisp`, containing:

```
(in-package "CL-USER")
(load-all-patches)
(save-image "~/lw-console"
           :console t
           :multiprocessing t
           :environment nil)
```

Run LispWorks like this to create the new image `~/lw-console`:

```
lispworks-7-1-0-x86-linux -build /tmp/resave.lisp
```

### 13.3.6 Code signing in saved images

This section briefly describe when and how LispWorks images are code signed.

#### 13.3.6.1 Signing your development image

On Microsoft Windows and Mac OS X you can sign a development image saved using `save-image` with the `:split` argument.

### 13.3.6.2 Signing in the distributed LispWorks executable

The LispWorks Professional and Enterprise Edition images distributed are not signed, because of the complications around image saving and delivery that this would cause.

The LispWorks for Macintosh Personal Edition application bundle and the LispWorks for Windows Personal Edition executable are both signed in the name of LispWorks Ltd.

### 13.3.6.3 Signing your runtime application

On Microsoft Windows and Mac OS X you can sign a runtime executable or dynamic library which was saved using `deliver` with the `:split` argument.

## 13.4 Saved sessions

You can save a LispWorks session, which can be restarted at a later date. This allows you to resume work after restarting your computer.

Saving sessions is intended for users of the LispWorks IDE. The graphical tools described in *LispWorks IDE User Guide* provide the best way to use and configure session saving. However it is also possible to save a session programmatically, which is described in this section.

When you save a session, LispWorks performs the following three steps:

1. Closing all windows and stopping multiprocessing.
2. Saving an image. On Mac OS X this creates an application bundle.
3. Restarting the LispWorks IDE and all of its windows.

If a saved session is run later, then it will redo the last step above, but see “What is saved and what is not saved” on page 183 for restrictions.

Sessions are stored on disk as LispWorks images, by default within your personal application support folder (the exact directory varies between operating systems).

### 13.4.1 The default session

There is always a default session, which is used when you run the supplied LispWorks image.

When you run any other image directly, including a saved session or an image you created with `save-image`, it runs itself (not the default session).

Saved sessions are platform and version specific. In particular, a 32-bit LispWorks saved session cannot be the default session for 64-bit LispWorks, or vice-versa.

### 13.4.2 What is saved and what is not saved

All Lisp code and data that was loaded into the image or was created in it is saved. This includes all editor buffers, the Listener history and the value of `*`, `**` and `***`.

All threads are killed before saving, so any data that is accessible only through a `mp:process`, or by a dynamically bound variable, is not accessible.

All windows are closed, so any data that is accessible only within the windowing system is not accessible after saving a session.

The windows are automatically re-opened after saving the session and all Lisp data within the CAPI panes is retained.

External connections (including open files, sockets, database connections and COM interfaces) become invalid when the saved session is restarted. In the image from which the session was saved, the connections are not explicitly affected but if these connections are thread-specific, they will be affected because the thread is killed. In recreated Shell tools the command history is recovered but the side effects of those commands are not. Debugger and Stepper windows are not re-opened because they contain the state of threads that have been killed.

### 13.4.3 Saving a session programmatically

You can save a session by calling `save-current-session`

### 13.4.3.1 Save Session actions

The first thing that `save-current-session` does is to execute the action-list "Save Session Before".

After redisplaying all the interfaces, the action-list "Save Session After" is executed. That happens both in the saving invocation and the restarting saved image.

### 13.4.3.2 Non-IDE interfaces

If there are non-IDE interfaces on the screen when `save-current-session` is invoked, there interfaces are destroyed in the first step, and displayed again in the third step. Note that the display will occur in a different thread than the one running the interface before the saving (which was killed in the first step).

If the interface (or any of its children) contains information that is normally destroyed (in some sense) in the `destroy-callback`, this information can be preserved over a call to `save-current-session` by defining methods on the generic functions `capi:interface-preserving-state-p` or `capi:interface-preserve-state`.

### 13.4.4 Saving a session using the IDE

You can save a session or set up periodic automatic session saving using the configuration tools in the LispWorks IDE. See "Session Saving" in the *LispWorks IDE User Guide* for details.

## 13.5 Load and open your files on startup

Suppose you always compile and load several files after LispWorks starts. You can arrange for this to happen automatically by adding forms like these in your initialization file:

```
(defvar *my-files*
  '("/path/to/foo1"
    "/path/to/foo2"
    "/path/to/foo3"))

(dolist (file *my-files*)
  (compile-file file :load t))
```

If you also want to open these files in the Editor tool, then you can add this form in your initialization file, after those above:

```
(define-action "Initialize LispWorks Tools"
  "Open My Files"
  #'(lambda (screen)
      (declare (ignore screen))
      (dolist (file *my-files*)
        (ed file))))
```

## 13.6 Customizing the editor

This section explains some of the customizations you can make to the Editor tool in the LispWorks IDE.

### 13.6.1 Controlling appearance of found definitions

The commands `Find Source`, `Find Source for Dspec` and `Find Tag` retrieve the file containing a definition and place it in a buffer with the relevant definition visible. By default, the start of the definition is in the middle of the Editor window and is highlighted.

The variable `editor:*source-found-action*` controls the position and highlighting of the found definition. The value should be a list of length 2.

The first element controls the positioning of the definition, as follows:

`t` Show it at the top of the editor window.

A non-negative fixnum

Position it that many lines from the top.

`nil` Position it at the center of the window.

The second element can be `:highlight`, meaning highlight the definition, or `nil`, meaning don't.

For example, to configure the editor so that found definitions are positioned at the top of the window and are not highlighted, do

```
(setq editor:*source-found-action* '(t nil))
```

This variable is set in the file `a-dot-lispworks.lisp`.

### 13.6.2 Specifying the number of editor windows

You can specify the maximum number of editor windows that are present at any one time. For example, to set the maximum to 1:

```
(setq editor:*maximum-ordinary-windows* 1)
```

This variable is set in the file `a-dot-lispworks.lisp`.

### 13.6.3 Binding commands to keystrokes

You can bind existing editor commands to different keystrokes, using `editor:bind-key`.

The LispWorks file `config/key-binds.lisp` is supplied. It shows the standard Emacs key bindings for LispWorks.

The following example shows how to rebind `?` so that it behaves as an ordinary character in the echo area of tools in the LispWorks IDE — this can be useful if your symbol names include question marks.

```
(editor:bind-key "Self Insert" #\? :mode "Echo Area")
```

Since `?` is then no longer available for help, you may wish to rebind help to `Ctrl+?`.

```
(editor:bind-key "Help on Parse" "Control-?" :mode "Echo Area")
```

If you use another editor emulation, then see the LispWorks file `config/msw-key-binds.lisp` or `config/mac-key-binds.lisp` for the corresponding `editor:bind-key` forms.

## 13.7 Finding source code

**Note:** This section does not apply to LispWorks Personal Edition.

To configure LispWorks so that editor commands such as `Find Source`, the menu command `Find Source`, and the dspec system are able to locate definitions in the supplied editor source code:

1. Load the logical host for the editor source code:

```
(load-logical-pathname-translations "EDITOR-SRC")
```

2. Configure source finding to know about editor source code:

```
(setf dspec:*active-finders*
      (append dspec:*active-finders*
              (list "EDITOR-SRC:editor-tags-db")))
```

3. Now do (for example) **Meta+X Find Command Definition** and enter **Wfind File**.

The definition of the command **Wfind File** is displayed in an Editor tool.

See “Controlling appearance of found definitions” on page 185 for information on controlling how the source code is displayed.

## 13.8 Controlling redefinition warnings

By default most system-provided definers such as `c1:defun`, `c1:defmacro`, `c1:defmethod` and so on signal a warning when they redefine an existing definition. You can bind or set `*redefinition-action*` to eliminate such warnings or make it signal error instead.

Also, the system is configured to protect symbols in implementation packages against definition and redefinition. For example, an error is signaled if you attempt to put a function definition on the symbol `c1:*read-base*`. This behavior is configurable by the variables `*handle-warn-on-redefinition*` and `*packages-for-warn-on-redefinition*`. Bear in mind that the default configuration protects the stability of the system, so if you need to prevent such errors it is better to bind one or both of these variables around specific defining forms, rather than setting their global values.

## 13.9 Specifying the initial working directory

The working directory is set on startup and provides the default location for the **File > Open...** dialog. Call `change-directory` in your initialization file (see “Initialization files” on page 178) to control the initial working directory.

## 13.10 Using ! for :redo

The default way of redoing the previous command from the command history is via `:redo`. If you want to use `!` (exclamation mark) instead of `:redo`, add the following to your `.lispworks` file:

```
(set-macro-character #\\!
 #'(lambda (stream char)
   ':redo))
```

You may wish during some sessions to reset `!` back to its normal role as a character. To do this, evaluate:

```
(set-syntax-from-char #\\! #\\@)
```

## 13.11 Customizing LispWorks for use with your own code

This section contains some information on customizations you can make in order to make developing your own code a little easier.

### 13.11.1 Preloading selected modules

If you frequently use some code that is normally supplied as separate modules, you can load them at start-up time from your initialization file. This file is called `.lispworks` by default, but can be changed to be any other filename. See “Setting Preferences” in the *LispWorks IDE User Guide* for details.

For example, to load the dynamic-completion code every time you start LispWorks, include the following in your initialization file.

```
(require "dynamic-complete")
```

### 13.11.2 Creating packages

When writing your own code that uses, for instance, the `capi` package, create a package of your own that uses `capi` — do not work directly in the `capi` package. By doing this you can avoid unexpected name clashes.

## 13.12 Structure printing

By default `defstruct` generates a method on `print-object`. You can avoid this by binding at macroexpansion time the variable `structure:*defstruct-generates-print-object-method*`.

## 13.13 Configuring the printer

This section applies only on non-Windows platforms when running the Motif IDE.

You can configure your LispWorks image for your printer, by selecting **File > Printer Setup** from any tool with printing capacities, for example the editor, and choosing **Add Printer**.

When configuring a printer, the CAPI printing library prompts for a *PostScript Printer Description* file (PPD), which defines such things as the paper size and the printable area of the page, in the form of a standard PostScript language header. The printing code splices this file into the PostScript produced from submitting a CAPI printing request.

The library on the LispWorks CD contains a generic PPD file, called `generic.ppd`, that defines these values conservatively to ensure that it should work with most printers. For accurate results, you should use the PPD supplied with your printer.

The PPD files are placed in the `ppd` subdirectory of the `postscript` directory in the `lispworks` library directory. Files added to the `ppd` directory are expected to have the extension ".`ppd`".

### 13.13.1 PPD file details

A PPD file contains a description of the attributes and capabilities of a given printer, such as paper sizes supported, the printable area of the page, the number and names of input paper trays, optional features such as additional paper trays or duplex units, and so on, together with the printer-specific PostScript language commands necessary to use the features.

The file `generic.ppd` defines a simple generic printer supporting A4, A3, US letter, and US legal paper sizes, and supporting manual feed. It defines con-

servative margins (1 inch all round), and the documents generated should be compatible with most PostScript printers. It is suitable for producing PostScript files when the destination printer is unknown, and may also be used if the appropriate PPD for the printer is not available.

However, for the best results, we recommend the use of the appropriate PPD for the printer. This allows you to specify which optional features (if any) have been installed on the printer, and ensures that the Print dialog provides access to appropriate printer capabilities such as multiple input trays and duplex printing. This also ensures that the CAPI uses the correct values for the printable areas of the page.

# LispWorks as a dynamic library

This chapter describes how to create a dynamic library or DLL from LispWorks and discusses use of the library.

## 14.1 Introduction

You can use LispWorks to build a dynamic library on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD.

To do this, use `save-image` or `deliver` and supply a list value for *dll-exports*. On platforms other than Windows passing *dll-added-files* also creates a dynamic library.

The result is a library that cannot be executed on its own, but can be dynamically loaded by another process. On Windows this is done with the Windows APIs `LoadLibrary` and then `GetProcAddress`. On other platforms the dynamic library can be loaded by `dlopen` and then `dlsym`.

The dynamic library is usually of file type `dll` on Windows, `dylib` on Macintosh and `so` on Linux, x86/x64 Solaris or FreeBSD. The first implementation of this functionality in LispWorks was on Microsoft Windows only, therefore the terminology that is used is sometimes Windows-like. In particular “DLL” refers to any dynamic library.

A program that loads a LispWorks dynamic library must be compiled and linked as follows:

Linux	Link with <code>libpthread.so</code>
FreeBSD	Link with <code>libpthread.so</code>
Mac OS X	No special requirements
Solaris	Compile and link multithreaded (for example, using the <code>-mt</code> option to Oracle's <code>cc</code> )

## 14.2 Creating a dynamic library

To deliver a LispWorks runtime as a dynamic library supply a list value for *dll-exports* when calling `deliver`.

To save a LispWorks image as a dynamic library supply a list value for *dll-exports* when calling `save-image`.

Additionally on Linux, x86/x64 Solaris, Macintosh and FreeBSD platforms, you can supply a list value for *dll-added-files* to deliver or save a dynamic library.

**Note:** a LispWorks dynamic library is licensed in the same way as a LispWorks executable.

### 14.2.1 C functions provided by the system

When LispWorks is a dynamic library the functions described in Chapter 54, “Dynamic library C functions” are automatically available. They allow the loading process control over relocation and unloading of the library.

### 14.2.2 C functions provided by the application

*dll-exports* specifies application-defined exported functions in a LispWorks dynamic library.

Exports can also be provided in the files named in *dll-added-files*, on Linux, x86/x64 Solaris, Macintosh and FreeBSD platforms.

### 14.2.3 Example

This script saves an image `hello.dll` which is a Windows DLL:

```
----- hello.lisp -----
(in-package "CL-USER")
(load-all-patches)
;; The signature of this function is suitable for use with
;; rundll32.exe.
(fli:define-foreign-callable ("Hello"
                               :calling-convention :stdcall)
  ((hwnd w:hwnd)
   (hinst w:hinstance)
   (string :pointer)
   (cmd-show :int))
  (capi:display-message "Hello world"))

(save-image "hello"
            :dll-exports '("Hello")
            :environment nil)
-----
```

Run the script by

```
lispworks-7-1-0-x86-win32.exe -build hello.lisp
```

on the command line, or use the Application Builder tool.

(See “Saving a LispWorks image” on page 179 for more information about how to save an image.)

You can test the DLL by running

```
rundll32 hello.dll,Hello
```

on the command line.

To see the dialog, you may need to dismiss the LispWorks splashscreen first.

## 14.3 Initialization of the dynamic library

Each of the exports specified via *dll-exports* ensure first that LispWorks has finished initializing. If initialization has not yet started, they start the initialization process themselves. This is true regardless of the value of *automatic-init* (see below).

A LispWorks dynamic library is initialized automatically on loading, or not, according to the value of *automatic-init* in the call to `deliver` or `save-image`.

### 14.3.1 Automatic initialization

On Microsoft Windows when *automatic-init* was true the initialization finishes before the Windows function `LoadLibrary` returns, and if LispWorks fails for some reason then the call to `LoadLibrary` fails too.

On other platforms when *automatic-init* was true, during the automatic initialization `dlopen` just causes the initialization to start and returns immediately. The initialization will finish sometime later. The LispWorks function `LispWorksState` can be used to check whether it finished initializing.

Automatic initialization is useful when the dynamic library is something like a server that does not communicate by function calls. On Windows it also allows `LoadLibrary` to succeed or fail according to whether the LispWorks dynamic library initialized successfully or not.

### 14.3.2 Initialization via `InitLispWorks`

Not using automatic initialization (that is, creating the dynamic library with *automatic-init nil*) allows using `InitLispWorks` to relocate the image if necessary, and do any other initialization that may be required.

## 14.4 Relocation

LispWorks normally maps its heap on startup in the same place that it was when it was saved, and when it needs more memory it maps this nearby. This applies when LispWorks is a dynamic library as well as for LispWorks executables.

This mapping can cause memory clashes with other software, which may be avoided by relocating LispWorks. Most of the LispWorks implementations are relocatable though the details vary between platforms and between 32-bit LispWorks and 64-bit LispWorks.

On Microsoft Windows and Macintosh, LispWorks detects and avoids memory clashes automatically. On other platforms, you can relocate a LispWorks dynamic library (for all the relocatable implementations) if necessary by a

suitable call to `InitLispWorks` as described in “Startup relocation” on page 459.

## 14.5 Multiprocessing in a dynamic library

Multiprocessing is started automatically in a LispWorks dynamic library. Therefore you can arrange for Lisp initialization operations by adding process specifications to `*initial-processes*`.

For example, if you have a function like this:

```
(defun my-server ()
  (let ((s (establish-a-socket)))
    (loop (accept-connection s))))
```

you need to do something like:

```
(pushnew '("My server" () my-server) mp:*initial-processes*
         :test 'equalp)
```

before saving or delivering your library.

## 14.6 Unloading a dynamic library

Before a LispWorks dynamic library is unloaded, LispWorks should be made to ‘quit’ cleanly, allowing it to clean up resources that it uses.

When the LispWorks dynamic library is loaded by a main process which you (the LispWorks programmer) do not control, then use `dll-quit`. If you control the main process, then use `QuitLispWorks` instead. For the details, see the respective manual entries for `dll-quit` and `QuitLispWorks`.

# 15

---

## Java interface

The LispWorks Java interface allows you to:

- Define "Java Callers" which are Lisp functions that call Java methods or constructors, or access Java fields. You can either define specific callers, or "import a Java class", which means automatically generating callers for all the class public methods, constructors and fields.
- Make and access Java arrays.
- Make calls from Java into Lisp, either by calling Lisp directly or making proxies that implement some Java interface ("Lisp proxy"), and using a Lisp proxy where Java requires an object that implements an interface.
- Access Java objects.
- Integrate Java in a limited way with CLOS.
- Make socket streams using Java sockets. See "Socket streams with Java sockets and SSL on Android" on page 432.

Calling into Java using the callers and accessing arrays does not require any specific Java code. Calling from Java into Lisp requires having the `com.lisp-works.LispCalls` class (supplied as a JAR file), and using methods from it.

The Java interface is a module which needs to be loaded by calling

```
(require "java-interface")
```

The Java interface symbols are exported from the package LW-JI, documented in Chapter 41, “The LW-JI Package”.

The Java interface requires Java edition 6 or later.

## 15.1 Types and conversion between Lisp and Java

### 15.1.1 Mapping of Java primitive types to and from Lisp types

The 8 primitive Java types map naturally to Lisp types:

Table 15.1 Mapping from primitive Java types to Lisp types

Java	Lisp
<code>long, int, short, byte</code>	<code>integer</code>
<code>double</code>	<code>double-float</code>
<code>float</code>	<code>single-float</code>
<code>char</code>	<code>integer</code>
<code>boolean</code>	<code>(member t nil)</code>

The mapping from Lisp to Java is not always obvious, for example because a Lisp integer can map to `long, int, short, char` or `byte`. In most cases, like method calls, the target Java type is known. In these cases, LispWorks allows `integer` in the acceptable range for `byte, short, int, long` and `char`, any Lisp float for `float` and `double`, `t` and `nil` for `boolean`.

When the target is not known, like storing a value in a Java array object (that is type `java.lang.Object[]`) or using `lisp-to jobject`, LispWorks uses this mapping:

Table 15.2 Mapping from Lisp when target Java type is unknown

Lisp	Java
Integers that fit in 32 bits	<code>int</code>

Table 15.2 Mapping from Lisp when target Java type is unknown

Lisp	Java
Integers that do not fit into 32 bits but fit into 64 bits	<code>long</code>
Double floats	<code>double</code>
Other floats	<code>float</code>
<code>t</code> or <code>nil</code>	<code>boolean</code>
Other Lisp values	Cannot be converted.

LispWorks has a set of keywords and FLI types to match the primitive types, which can be used to specify these types, for example as the type of an array. The keyword names are the Java name (uppercase), and the FLI type names are the Java name preceded by J (and uppercase), exported from LW-JI. These are shown in the table below.

Table 15.3 Keywords and FLI types matching primitive types

Java type	Keyword	FLI type	Underlying FLI type
<code>short</code>	<code>:short</code>	<code>jshort</code>	<code>:short</code>
<code>long</code>	<code>:long</code>	<code>jlong</code>	<code>:int64</code>
<code>byte</code>	<code>:byte</code>	<code>jbyte</code>	<code>:byte</code>
<code>char</code>	<code>:char</code>	<code>jchar</code>	<code>(:unsigned :short)</code>
<code>double</code>	<code>:double</code>	<code>jdouble</code>	<code>:double</code>
<code>float</code>	<code>:float</code>	<code>jfloat</code>	<code>:float</code>
<code>boolean</code>	<code>:boolean</code>	<code>jboolean</code>	<code>(:unsigned :char)</code>
<code>int</code>	<code>:int</code>	<code>jint</code>	<code>:int</code>

**Note:** The Java type `char` (and hence the class `Character`) corresponds to UTF-16 code units, which is equivalent to `unsigned short`. It does not corre-

spond to Unicode characters, and therefore cannot be mapped to LispWorks characters.

### 15.1.2 `java.lang.String`

LispWorks deals specially with `java.lang.String` objects, converting them automatically to Lisp strings when receiving them (return value of methods or arguments to calls into Lisp), and converting Lisp strings to `java.lang.String` when passing them (argument to method calls, return values from calls into Lisp). It is therefore possible to think of strings as another primitive type. The overhead associated with this conversion for short strings (tens of characters) is smaller than the overhead associated with passing a Java non-primitive object. Even for larger strings, the fact that all the data in the string is passed in one call without further Java/Lisp interaction make it an effective way of passing data.

### 15.1.3 Java non-primitive objects

All Java non-primitive objects are represented in LispWorks as foreign pointers of type `jobject`. `jobject` is a proper Lisp type, that is you can use `c1:typep` and specialize methods on it. The actual Java class of the object is not consistently represented, unless you explicitly ask for it using `jobject-class-name`. You can get a string describing the Java object in the way that Java "thinks" (that is the result of `toString`) using `jobject-string`. If you need a Java null value, then you can use the constant `*java-null*`.

Instances of `standard-java-object` are also considered to represent Java objects. `standard-java-object` instances have a slot that contains the actual `jobject`, which is used when an instance of `standard-java-object` is passed to the interface functions. In the text below, when argument is specified as "java-object" or "Java object", it can be either a `jobject` or an instance of `standard-java-object`.

## 15.2 Calling from Lisp to Java

To call into Java you typically define Java callers. There are two possible approach for defining the callers: importing classes or defining specific callers.

In addition, you can call Java methods and constructors and access Java fields without defining them first.

### 15.2.1 Importing classes

Importing a Java class means that the system generates definitions for all the public methods, constructors and fields for this class. For example, to generate and evaluate the definition, execute:

```
(import-java-class-definitions "java.io.File")
```

And to write the definitions to a file:

```
(write-java-class-definitions-to-file "java.io.File"
"filename.lisp")
```

The import macros and functions all take various keyword arguments to control exactly what they generate.

`import-java-class-definitions` would normally appear as a top level form in your source file, and when the file is loaded it generates all the definitions. `write-java-class-definitions-to-file` can be used to generate all the definitions and write them to a file, which is an ordinary Lisp source file that can be compiled and loaded as usual. There is also `write-java-class-definitions-to-stream`, which writes the definitions to a stream, and `generate-java-class-definitions`, which returns a list of the definitions, which may be useful sometimes (they are actually used by `import-java-class-definitions` and `write-java-class-definitions-to-file`).

The actual definitions that the importing interface generates are the same as you would write yourself, using the appropriate defining forms: `define-java-caller`, `define-java-constructor`, `define-field-accessor`. These are discussed further in “Defining specific callers” on page 202.

Importing has the obvious advantage that you do not need to type all the method names. It has two disadvantages:

- The generation of the definitions relies on having access to the class definition and running Java virtual machine (JVM), which may or may not be a hassle. For example, if your code contains an `import-java-class-definitions` form, it will need the JVM running and the class defini-

tion accessible when it is loaded as source or when it is compiled (loading the binary file does not require Java).

If the requirement for Java is an issue, you can work around it using `write-java-class-definitions-to-file` (or use `write-java-class-definitions-to-stream`), and use the resulting file as your source code. The call to `write-java-class-definitions-to-file` requires Java, but you need to do it only once, and it can be on a different computer to the one you develop on. For a public class (standard Java, standard Android) you can even ask Lisp Support to create the file for you. This approach also allows you to edit the definitions if you have any reason to. The definitions also contain the signatures of all the methods and constructors.

- The other disadvantage of importing is that it "pollutes" your namespace with many definitions, of which you may be needing only a few. To reduce the chances of clashes, the default setting creates a Lisp package for each Java package, and uses a unique name for the package. This makes the code less Lisp-like. Using the keywords to import interface allows you some control on the naming that it uses.

If you deliver your application without shaking (the default for levels 0 and 1), using import will also cause your application to be larger than it needs to be. If you import many classes this difference may be significant. If you deliver with shaking (default for level 2 or higher), the callers that are not used will get shaken out and so will not affect the size of your application.

### 15.2.2 Defining specific callers

You define specific callers by using the various definers, which are typical defining macros, but the body is automatically generated:

`define-java-caller`

Defines a caller that calls a Java method.

`define-java-callers`

Defines several method callers for the same class.

`define-java-constructor`

Defines a caller that calls a Java constructor method.

```
define-field-accessor
```

Defines callers to access (read and write) a field.

In addition, you can define callers dynamically at run time using the `setup-*` functions `setup-java-caller`, `setup-java-constructor` and `setup-field-accessor`, which are functions that match the `define-*` macros above.

The `setup-*` functions effectively do exactly what the `define-*` macros do, but the code looks nicer with the macros, and the LispWorks Editor can find your definitions.

Methods and constructors are similar enough that they are described here together. Constructors are by definition always "static" in the Java terminology.

Defining a caller for a method or constructor defines a Lisp function that when called invokes the Java method. The Java method is supplied by its class name and name (except constructors, which implicitly map to the constructor methods of the class), which means that there may be more than one Java methods or constructor that are applicable.

For example:

Define a Lisp function `my-probe-file` which invokes the Java method `java.io.File.exists`:

```
(define-java-caller my-probe-file "java.io.File" "exists")
```

Define a Lisp function that calls one of the constructors of `java.io.File`:

```
(define-java-constructor my-make-file "java.io.File")
```

At run time, `my-make-file` will check which of the constructors of `java.io.File` matches the arguments, and then call it.

See “Actual Java call” on page 205 for a description of how the callers actually work.

Defining a field accessor defines a Lisp function that reads the field value, potentially another Lisp function to set the value (if it is not final), and a symbol macro that expands to calls to the getter or setter. For ordinary (non-static)

fields, the getter needs to be called with the object from which to read the value, and the setter must be called with the object and the value. For static fields, the getter takes no arguments, and the setter takes the new value.

### 15.2.3 Verifying callers

Compared to importing classes, explicit definitions have the advantages that they do not need Java running until run time, you define only the callers you need, and you select the names of the Lisp functions. The main disadvantage is that you have to type much more, and that you may have typing errors in the method names which are not reported during compilation.

The functions `verify-java-caller` and `verify-java-callers` are provided as a way to guard against such typing errors. These functions need Java running, and they check whether the callers have matching Java methods, and return information about missing methods. The intention is that at least during development, you will call `verify-java-callers` at the beginning of the application and log the result, which will allow you to check whether any method is missing. It may also be useful if you use classes whose definitions may change, for example when the Java code and Lisp code are developed in parallel, or when you use non-standardized Java code.

`verify-java-caller` and `verify-java-callers` force the caching of run time information that the callers normally do in their first call.

### 15.2.4 Calling methods without defining callers

You can call Java methods by passing the full *method-name* as a string "`package.class.method`" to `call-java-method`. The actual run time behavior is as described in "Actual Java call" on page 205.

**Note:** `call-java-method` caches the relevant information using the string as the key, while properly defined callers close over it. Therefore `call-java-method` is slightly slower, but the difference is not significant. The only significant difference is that you can verify the caller to check against typing errors, while with `call-java-method` you will find a typing error in the method or class name only when you call it. If you find using `call-java-method` convenient and do not need the verification, there is no reason not to use `call-java-method` in preference to defining the callers explicitly.

You can construct an object of a class by calling `create-java-object`, supplying the full class name followed by the arguments to the constructor. The actual run time behavior is as described in “Actual Java call” on page 205.

You can access fields without defining accessors using `read-java-field` and `set-java-field`. There is also `checked-read-java-field`, which is like `read-java-field` but does not error on failure, `check-java-field` to check whether a field exists, and `java-field-class-name-for-setting` to find the class of the value.

### 15.2.5 Actual Java call

When a Java caller is called the first time or a call without definition is done and not cached yet, the function finds the relevant method(s), their arguments and return value types, and caches it (see `verify-java-caller` or `verify-java-callers` for pre-caching). That includes finding the class, and then finding the relevant methods or constructors. It then uses this information to decide which method is applicable, how to convert the argument to Java where needed, and how to convert the return value back to Lisp. It also decides which JNI function to use to perform the actual call.

Before doing the call LispWorks checks whether the arguments are of the correct type, and in most of the cases can catch and give Lisp errors as appropriate before calling into Java.

For an ordinary (non-static) Java method, the arguments to the Lisp function must start with the actual Java object for which the method needs to be applied. The rest of the arguments to the Lisp function are passed to the method. Thus the number of the arguments to the Lisp function needs to be one more than the number of (explicit) arguments to the Java method. The invocation is virtual (normal Java invocation), which may mean that the actual Java method that is ultimately executed may be defined in a subclass of the class that passed to the definer, if the object belongs to this subclass.

For static Java methods (including constructors) the given argument list is passed to the method.

## 15.3 Calling from Java to Lisp

Calling from Java to Lisp requires the Java class `com.lispworks.LispCalls`, and Java code that uses methods from this class. Currently all methods are static. `com.lispworks.LispCalls` is supplied by LispWorks in the file `7-1-0-0/etc/lispcalls.jar`, except on Android where it is part of the `7-1-0-0/etc/lispworks.jar` file. After Java is initialized, either by an explicit call to `init-java-interface` or implicitly by the system (for example on Android), you can check whether the Java to Lisp calls are possible (the class `LispCalls` is available) by using `check-lisp-calls-initialized`.

There are two mechanisms for calling from Java to Lisp: direct calls and using proxies. Direct calls means calling directly a Lisp function from Java, passing the name of the symbol to funcall and the arguments. Using proxies meaning creating proxies from Lisp, and then passing such Lisp proxies to places where the interface(s) that it implements are required. Invoking a method on such proxy ultimately calls a Lisp function.

Direct calls are simple to use, and if you have a simple Java/Lisp interface can be all that you need. The proxies are needed when you use somebody else's interface, for example implement callbacks to user interaction in Android. They are also useful even if you write the Java side too to make a cleaner interface on the Java side, which is easier to switch between different implementations.

### 15.3.1 Direct calls

You can make direct calls from Java to Lisp using one of the `Call<type>[VA]` static methods from `LispCalls`, which have these signatures:

```

public static int callIntV(String name, Object... args)
public static int callIntA(String name, Object[] args)
public static double callDoubleV(String name, Object... args)
public static double callDoubleA(String name, Object[] args)
public static Object callObjectV(String name, Object... args)
public static Object callObjectA(String name, Object[] args)
public static void callVoidV(String name, Object... args)
public static void callVoidA(String name, Object[] args)

```

The `<type>` in `Call<type>[VA]` specifies the return type, and `V` or `A` specify whether the arguments are supplied as `Variable` arguments or `Array`. Otherwise the pairs of `V` and `A` methods behave the same.

All these methods apply the Lisp symbol which is named by the `name` argument to the arguments supplied by the `Array` or the `variable` arguments, and return the result.

Note that on the Lisp side you will need to keep the Lisp symbol when delivering, most conveniently by `hcl:deliver-keep-symbols` (see the *LispWorks Delivery User Guide*), and the name of the symbol is not interpreted using `cl:read`.

See `com.lispworks.LispCalls` for full details.

### 15.3.2 Using proxies

Using proxies allows you to create from inside Lisp a Java proxy which implements one or more Java interfaces. The proxy can then be used whenever an object that implements any of the interfaces is required. When a method is applied to a proxy, it ultimately calls a Lisp function.

Creating a proxy in Lisp is done in two steps:

1. Defining a proxy, specifying
  - i) A name (a symbol).
  - ii) The interfaces that it implements.
  - iii) The Lisp functions that get called for each method.

- iv) A default function.
- v) Several other options.

Above, i) and ii) are obligatory, the other steps are optional.

Defining a proxy is done normally at load time by `define-lisp-proxy`. It is possible to define a proxy at run time using `setup-lisp-proxy`. For example, defining a proxy that implements the `onTouchListener` interface, specifying that when the method "onTouch" is invoked it causes the function `text-view-on-touch-callback` to be called:

```
(define-lisp-proxy my-text-view-on-touch-proxy
  ("android.view.View.OnTouchListener"
   ("onTouch" text-view-on-touch-callback)))
```

2. Making a proxy object using the name of a proxy definition by `make-lisp-proxy` or `make-lisp-proxy-with-overrides`, or by calling inside Java the method `com.lispworks.LispCalls.createLispProxy`. The result of making a proxy is a Java proxy object, which can be used in Java. For example, assuming the definition above and that you have a `View` in `mTextView`:

```
Object listener = LispCalls.createLispProxy("MY-TEXT-VIEW-ON-TOUCH-PROXY");
// Check the type of listener to allow for errors in Lisp
if (listener instanceof View.OnTouchListener)
    mTextView.setOnTouchListener((View.OnTouchListener)listener);
```

This will cause the Lisp function `text-view-on-touch-callback` to be called whenever the `view` in `mTextView` is touched.

**Note:** the result of `make-lisp-proxy` or `make-lisp-proxy-with-overrides` is "local", which means that it cannot be used outside the dynamic scope of the call to Lisp from Java in which it was created. If it is created outside the scope of a call from Java to Lisp, it must be used only in the thread that it was created.

When defining a proxy, you do not need to specify all the methods. You can specify a default function, which is called for any method for which you did not specify a function. See for example the proxy `lisp-othello-server-lazy` in this example, which does not specify any method, and instead specifies a default function that handles all of them:

```
(example-edit-file "android/android-othello-user")
```

When defining a proxy, it is also possible to specify that the Lisp functions should be called with an extra argument *user-data*, which is associated with each specific proxy by passing `:user-data` to `make-lisp-proxy` or `make-lisp-proxy-with-overrides`. This allows you to link each proxy with some of your data. If you do not specify this option, the functions in the proxy need to use the arguments and global data to decide what to do.

It is also possible to "override" the Lisp function at run time, which means specifying that when a Lisp function for a method should be invoked, another function is invoked instead. Overriding is specified by passing either of `:overrides` or `:overrides-plist` to `make-lisp-proxy`, or by using `make-lisp-proxy-with-overrides`. The main advantage of overriding is that it allows you to use run time closures, while the proxy definition itself allows only symbols. Overrides are efficient and are simple to use. For example, with the definition above, you can override the callback by:

```
(let ((closed-something (creating-something)))
  (make-lisp-proxy 'my-text-view-on-touch-proxy
                  :overrides-plist
                  (list 'text-view-on-touch-callback
                        #'(lambda (&rest args)
                            (apply 'callback-with-something closed-
                                   something args)))))
```

which will cause a touch to invoke `callback-with-something` on `closed-something` and `args`.

Note that this example could easily be done using `:user-data` instead, but that will have to be specified "statically" in the proxy definition, while overriding can all done dynamically when creating individual proxies.

The Java method `com.lispworks.LispCalls.createLispProxy` cannot do overriding, it must be done inside Lisp by `make-lisp-proxy` or `make-lisp-proxy-with-overrides`.

To make it easier to detect typing errors in specifying the interface names and method names or specifying a Lisp function, the functions `verify-lisp-proxies` and `verify-lisp-proxy` are provided to verify all proxies or only one, respectively. Verification checks that all the specified functions are actually defined, and optionally also that all the methods that are declared in the

interfaces are defined. The latter check must be done with Java running. You will typically use it when starting the application to check that all the proxies are OK, at least during the development phase.

The Lisp functions of the proxy are ordinary Lisp, but they need to return the correct value, unless the method has `void` as its return type. Returning the wrong value will call the `java-to-lisp-debugger-hook` (see `init-java-interface`) with an appropriate condition, and then return zero of the correct type (that is 0, `0d0`, `0f0`, Java `false`, or Java `null`) from the method call.

The call to the Lisp function is wrapped such that trying to throw out of it does not actually finish the throw, and instead returns zero of the correct type from the method call.

In some cases the method needs to throw some exception. The function `throw-an-exception` can be used to throw an exception from inside a call to a proxy function.

## 15.4 Working with Java arrays

Java arrays are represented inside Lisp by a `jobject` or an instance of `standard-java-object`, like any other Java object. The function `java-array-element-type` returns the element type of a Java array or `nil` if it is not an array, and it is fast enough that it can be used as a predicate to determine whether a `jobject` represents an array.

`java-array-length` returns the length of a Java array.

`java-primitive-array-element-type` and `java-object-array-element-type` return the same values as `java-array-element-type` for an array of primitive type or an array of non-primitive type respectively, otherwise they return `nil`. They are fast and can be used as predicates to decide whether an array is of primitive type or not.

Java arrays of higher dimensions are represented recursively as vectors of vectors, which affects the way you use the accessors.

### 15.4.1 Accessing a single element

The accessor `jvref` can be used to get and set (with `c1:setf`) the value in a Java "Vector" (that is, a one-dimensional array). For a multi-dimensional array,

`jvref` gets and sets the first level "Vector", in other words it returns another array of one less dimension.

`jaref` can be used to get and set elements of arrays with any number of dimensions. If the number of dimensions given is less than the rank of the array, it gets or sets the corresponding sub-array.

Both `jvref` and `jaref` can be used to access arrays of any type. `jvref` is slightly faster, and does not allow passing wrong number of arguments.

**Note:** when accessing an element of a multi-dimensional array, `jaref` needs to get the sub-arrays for the sub-dimensions. This means it is relatively inefficient when used to access elements in the same sub-array. It is more efficient to get the sub-array and access it. For example, instead of

```
(dotimes (z 10)
  (do-something (jaref java-array 3 4 z)))
```

use

```
(let ((sub-array (jaref java-array 3 4)))
  (dotimes (z 10)
    (do-something (jvref sub-array z))))
```

Assuming `java-array` is not a primitive array, it is even better to use the multiple access functions:

```
(let ((sub-array (jaref java-array 3 4)))
  (map-java-object-array 'do-something sub-array :end 10))
```

### 15.4.2 Making Java arrays

The function `make-java-array` is used to make Java arrays of any rank and type. It takes as first argument a class specifier, followed by the dimension(s). The class specifier specifies the type of the elements in the array, which may be any type (both primitives and proper classes).

It is also possible to create primitive arrays with data copied from Lisp arrays using `lisp-array-to-primitive-array`.

### 15.4.3 Multiple access functions

The multiple access functions are used to access elements in one-dimensional arrays ("Vectors"). They are much more efficient than accessing each element separately.

Multiple access of primitive and non-primitives is done in a different way: non-primitive arrays are accessed by `map-java-object-array`, which maps a function on the objects in the array. Primitive arrays are accessed by `primitive-array-to-lisp-array` and `lisp-array-to-primitive-array` (copy to or from a Lisp array) or `get-primitive-array-region` and `set-primitive-array-region` (copy to or from a foreign array). String arrays are regarded as object arrays for this distinction.

`map-java-object-array` maps a function across an array. It has keyword arguments to control the actual operation, including specifying the range and direction, writing back the result of the call, and collecting the values. When called on multi-dimensional arrays, `map-java-object-array` accesses the top level elements, that is sub-arrays of one less dimension.

`primitive-array-to-lisp-array` and `lisp-array-to-primitive-array` take a Java primitive array or a Lisp array respectively, and copy the elements to a Lisp array or Java primitive array. Both functions can copy into an existing array or create the array themselves. Keyword arguments allow you to specify the range to copy.

Both `primitive-array-to-lisp-array` and `lisp-array-to-primitive-array` require the Lisp array element type to match exactly the Java array element type. The corresponding types are:

Table 15.4

Java array element type	Lisp array element type
<code>:int</code>	<code>(signed-byte 32)</code>
<code>:long</code>	<code>(signed-byte 64)</code>
<code>:short</code>	<code>(signed-byte 16)</code>
<code>:byte</code>	<code>(signed-byte 8)</code>

Table 15.4

Java array element type	Lisp array element type
:double	<code>double-float</code>
:single	<code>single-float</code>
:char	<code>(unsigned-byte 16)</code>
:boolean	<code>(unsigned-byte 8)</code>

`get-primitive-array-region` and `set-primitive-array-region` take a primitive array and copy part of it to or from a foreign array ("buffer"), which is passed as an FLI pointer.

## 15.5 Initialization of the Java interface

The Java interface is a module which needs to be loaded by calling:

```
(require "java-interface")
```

Before doing any calls from Lisp to Java or from Java to Lisp or creating any Java object from Lisp, the Java interface must be initialized by a call to `init-java-interface`. `init-java-interface` can either connect to an already running Java virtual machine, or load the JVM library and start it. It has various keyword arguments to set global values.

On Android and in dynamic libraries that were delivered with `setup-deliver-dynamic-library-for-java` with true for `init-java` (the default), the system automatically calls `init-java-interface` on startup.

Merely defining callers to Java and proxies does not use Java. Importing classes needs Java to do the expansion, so will require initializing the Java interface. See discussion in “Importing classes” on page 201.

## 15.6 Utilities and administration

Use `jobject-p` to test whether a Lisp object is a `jobject` or not.

Use `lisp-java-instance-p` to test whether the argument is an instance of `standard-java-object`.

`get-jobject` returns the `jobject` for a Java object, `nil` otherwise, and can be used as predicate to determine whether the argument is a valid Java object. Note that if you have an instance of `standard-java-object`, `get-jobject` may return `nil` if the slot is not set. `ensure-is-jobject` is like `get-jobject`, but signals an error if its argument is not a `jobject`.

`jobject-class-name` can be used to find the Java class raw name of a Java object. `jobject-pretty-class-name` makes it "pretty", which matches how it appears in the Java code.

`jobject-string` returns a string representing the object the way Java wants to represent it (the result of `Object.toString`).

`jobject-to-lisp` and `lisp-to-jobject` can be used to convert between Lisp and Java objects of primitive types, which may sometimes be useful.

`find-java-class` can be used to find the Java class object for class specification, which normally is the string representing the full class name, but can be also be a keyword for specific primitive types.

`jobject-of-class-p` can be used to verify whether a Java object is an instance of a class or any of its subclasses.

`reset-java-interface-for-new-jvm` eliminates cached Java objects from internal Lisp structures. It is intended to be used if you need to start a JVM, stop it and start again. Currently there is no interface to stop the JVM.

`intern-and-export-list`, `default-name-constructor`, `record-java-class-lisp-symbol`, `ensure-lisp-classes-from-tree` and `ensure-supers-contain-java.lang.object` are utility functions that are used by the definition generation code, and appear in the output of the importing interface (`write-java-class-definitions-to-file`, `write-java-class-definitions-to-stream` and `generate-java-class-definitions`). Their purpose is to be used by the importing interface, but if you find them useful you can call them directly.

`get-superclass-and-interfaces-tree` returns a tree of the superclasses and interfaces of a Java class. It is also used internally by the importing interface.

`send-message-to-java-host` can be used to send a message (a string) to the Java host. This is especially useful when the Lisp is used inside Java, for example on Android, so Java needs to do the displaying of messages to the user.

The variables `*to-java-host-stream*` and `*to-java-host-stream-no-scroll*` are output streams that send anything that is written to them to Java (by calling `send-message-to-java-host`). They can be used anywhere an output stream is needed to make the output go to the Java host.

The Java interface currently may generate at run time specific Java interface conditions of the types below.

Conditions with names ending `*-exception` are all subclasses of `java-exception`, and correspond to an exception raised while calling Java. `java-exception` has two subclasses: `java-normal-exception` for exceptions that you may get during normal execution, and `java-serious-exception`, for exceptions that indicate the system is broken in some way. `java-serious-exception` should never happen, while `java-normal-exception` may happen in normal code.

The other conditions correspond to errors which are detected inside Lisp.

The `java-exception` class has three readers, `java-exception-string`, `java-exception-java-backtrace` and `java-exception-exception-name`, which you can use when handling the condition. The macros `catching-java-exceptions` and `catching-exceptions-bind` can be used to catch Java exceptions instead of signaling an error. Your code can then access the Java exception directly.

#### `java-interface-error`

Superclass of the `*-error` conditions.

#### `java-definition-error`

Superclass of `java-class-error` and `java-method-error`.

#### `java-class-error`

Class not found.

#### `java-method-error`

Method not found.

**java-field-error**  
Field not found, or was defined with the wrong *static*-*p* value.

**java-field-setting-error**  
Setting a field failed, either because it is final or an unacceptable value was supplied.

**call-java-method-error**  
`call-java-method` failed to find the method.

**create-java-object-error**  
`create-java-object` failed to find constructors.

**java-array-error**  
Superclass of all array errors.

**java-out-of-bounds-error**  
Bad index passed to `jvref` or `jaref`, or bad *start* and *end* passed to other functions accessing arrays.

**java-storing-wrong-type-error**  
Trying to store value of wrong type into a Java array.

**java-exception**  
Superclass of the `*-exception` conditions.

**java-normal-exception**  
Superclass of normal exceptions.

**java-serious-exception**  
Superclass of serious exceptions.

Normal exceptions:

**field-exception**  
Superclass of field exceptions.

**field-access-exception**

Exception accessing a field (maybe wrong type of value).

`java-method-exception`

Exception inside a call to a Java method.

Serious exceptions:

`java-id-exception`

Failed to find JNI ID for a method.

`java-low-level-exception`

Failure in some JNI function.

## 15.7 Loading a LispWorks dynamic library into Java

When a LispWorks application is delivered as a dynamic library and is loaded by Java, the Java interface must be initialized at some point to make it possible to use it for interfacing with Java. Lisp code which does not interact with Java will work without initializing Java. This includes the initialization function (the first argument to `deliver`), which can do any required Lisp initialization. However, calls to Java and accepting calls from Java require initialization of the Java interface.

The function `setup-deliver-dynamic-library-for-java` is used to set this up. In the simple case, you just call `setup-deliver-dynamic-library-for-java` without any arguments, and then call `deliver`. When the resulting delivered Lisp image is loaded into Java, Lisp is initialized as usual, and then `init-java-interface` is automatically called with the host's Java virtual machine.

`setup-deliver-dynamic-library-for-java` forces the delivered image to be saved as a dynamic library, which when loaded by Java (normally by `System.loadLibrary` or `System.load`) receives the host's Java virtual machine, initializes the Java interface (unless `init-java` is passed as `nil`) and then calls its `function` argument if it is non-nil.

The `deliver` startup function (the first argument to `deliver`) is called before Java is initialized, so any code that needs to run before initializing the Java interface should be in this function.

By default the initialization is done synchronously, that is by the time that the Java method that loads the LispWorks delivered library returns, LispWorks has finished initializing and is ready to receive calls from Java and other foreign calls. As a result, the loading code on the Java side will hang until the initialization finishes. `setup-deliver-dynamic-library-for-java` can be told to make initialization asynchronous, that is the loading method just starts the initialization and returns immediately. Calls from Java into Lisp that occur before Lisp is ready will wait until Lisp is ready, and you can check if Lisp is ready by using the Java method `com.lispworks.LispCalls.waitForInitialization`.

`setup-deliver-dynamic-library-for-java` works by internally defining a foreign-callable for `JNI_OnLoad` and exporting it. You must not define this yourself when using `setup-deliver-dynamic-library-for-java`.

If you have your own C code that uses the JNI, you can pass the JVM to Lisp yourself via a foreign-callable (or return it from a lisp-to-foreign call), and call `init-java-interface` with it. In this case, you must not use `setup-deliver-dynamic-library-for-java`.

The function `get-host-java-virtual-machine` can be used to get the Java virtual machine that was passed from Java to the internally defined `JNI_OnLoad`, and can be used as a predicate to test if `JNI_OnLoad` was called. Thus you can create a dynamic library that may be loaded by Java or by a conventional mechanism, and use `get-host-java-virtual-machine` to distinguish between these two situations.

There is a minimal example of delivering LispWorks for Java in:

```
(example-edit-file "java/lisp-as-dll/README.txt")
```

## 15.8 CLOS partial integration

The integration of CLOS is mainly the fact that the functions that take a `jobject` also accept a CLOS instances of the class `standard-java-object`, which has a slot containing the `jobject` to use. That includes arguments to Java callers, Java arrays in the array interface, and return values from Lisp to Java. However, values that come from Java to Lisp (return values of caller, arguments in Java to Lisp calls), are always a `jobject` or primitives.

You can create a subclass of `standard-java-object` either by the usual way of including it (or a subclass of it) in the superclasses of your class, or by using the keywords arguments to importing functions and macro. To be able to construct a `jobject` for a class without the constructor, the `class-name` must be passed to `define-java-constructor`. This is done automatically by the importing functions.

When defining the class using the importing function, you can force it to create the complete hierarchy of superclasses to match all Java superclasses and implemented interfaces. This creates overhead and is not necessarily useful, but in some circumstances it may be what you need. You can also force the hierarchy explicitly by using `ensure-lisp-classes-from-tree`.

The `jobject` in an instance of `standard-java-object` can be read and written by the accessor `java-instance-jobject`. Alternatively you can call `create-instance-jobject` or `create-instance-jobject-list` to create the `jobject` for a given instance.

A simple interface for making an instance and its `jobject` together is `make-java-instance`, but this does not provide a way to pass arguments to `make-instance`. The initarg `:construct` to `make-instance` on a subclass of `standard-java-object` can be used to make the instance and the `jobject`. Note, however, that the `jobject` is created in the `c1:initialize-instance` method of `standard-java-object`, which may or may not be called before your `c1:initialize-instance` methods (depending on the order of the superclasses). To ensure that the `jobject` is created after the CLOS instance initialization is complete, do not pass the `:construct` initarg, and instead call `create-instance-jobject` or `create-instance-jobject-list` afterwards.

The argument to `create-instance-jobject-list` and to the `:construct` initarg is either a list of arguments to the constructor, or `t`, which means use the default arguments list. The default arguments list is created by calling `default-constructor-arguments` on the instance. The default method returns `nil`, which is good enough for some Java classes, but not all. Note that if you pass `:construct` to `make-instance`, `default-constructor-arguments` will be called on the instance before all the `c1:initialize-instance` methods have been called, which may be a problem if it depends on some values that may be put in by other `c1:initialize-instance` methods. To avoid

this issue use `create-instance-jobcet-list` with `t` on the result of `make-instance`.

If you have a `jobcet`, and there is a CLOS class defined for its Java class, you can create a CLOS instance for it using `create-instance-from-jobcet`. `create-instance-from-jobcet` finds the class using the record that is created by `record-java-class-lisp-symbol`. The call to `record-java-class-lisp-symbol` is done automatically by the importing interface, but you can also call it directly.

## 15.9 Java interface performance issues

Both Java and Lisp do memory management on their objects, which causes the interface between them to be problematic. The result is that calls between Java and Lisp are more expensive than calls from and to C, and that keeping a pointer to a Java object (`jobcets`) in Lisp adds overhead for both sides.

In general, code that needs to be efficient should not make calls between Lisp and Java. For interactive response on a mobile device, as a rough guide, if you have more than 100 calls between Lisp and Java per user gesture, you should reduce the number of such calls, or move the processing to another thread, so that the GUI is still responsive.

Keeping pointers to a Java object in Lisp (`jobcets`) creates an overhead both for Lisp (which needs to maintain a record so it can tell Java when it is free), and for Java. It is therefore a bad idea to keep large number of pointers to `jobcet` in Lisp. As a rough guide, when you reach 100 objects you should consider changing the interface.

Accessing the first dimension of an array can be done much more efficiently by the multiple access functions than the single element accessors. When accessing a multi-dimensional array, accessing more than one element in a sub-array can be done much more efficiently by getting the sub-array and accessing it instead of accessing via the top array.

If you pass to Lisp an array of Objects where Lisp goes through many of them and just reads one or two values, it is probably faster to put these values into a primitive array or string and pass this to Lisp instead. This avoids the creation of a `jobcet` and call(s) into Java for each object, which would be much more

expensive than the allocation of a primitive array and filling it in Java. The same is true in the other way.

If you need to pass a very large (megabytes) `Array` or `String` between Java and Lisp, it may be better to write it to a file and pass the filename.

# 16

---

## Android interface

To use LispWorks for Android Runtime, you need to have at least a minimal Android project written in Java, to load and initialize LispWorks. CAPI is not supported on Android, so any GUI part will need to be written in Java too.

To use the Android interface you need to deliver your application by the special image `lispworks-7-1-0-arm-linux-android`. This image does not contain the GUI part of LispWorks, but contains all the non-GUI parts.

This special image is an ARM image, and must be run on ARM architecture. That can be either an ARM machine, or an ARM emulator. To deliver a LispWorks for Android Runtime image using the QEMU emulator, you run the special image using the via the shell script `examples/android/run-lw-android.sh`

The Android interface relies on the Java interface, which is already loaded into the special image. You will typically also use the Java interface in your own code to make calls to Java methods, and define Lisp proxies that can be used inside Java, though in principle the whole interface may be done via direct calls from Java into Lisp, without using the Java interface explicitly.

The interface for Android includes the following:

- The function `deliver-to-android-project`, which is the function that you use to deliver LispWorks code for Android. The files delivered are a

dynamic library and a Lisp heap, which can then be loaded by and initialized by the Java `com.lispworks.Manager.init` method. By default it delivers the library and heap directly into the directory structure of an Android project.

- A JAR file containing a few classes in the `com.lispworks` package to support the Java/Lisp interface. This includes these classes:

`com.lispworks.Manager`

Defines the method `com.lispworks.Manager.init` to load and initialize LispWorks, error reporting interface and some basic utilities.

`com.lispworks.LispCalls`

Defines direct callers into Lisp, and support for Lisp proxies (which are Java proxies that call Lisp functions). `LispCalls` is really part of the general LispWorks Java Interface.

`com.lispworks.BugFormLogsList` and `com.lispworks.BugFormViewer`

Two activities to help display errors during development.

- A few Android-specific interface functions:

`android-funcall-in-main-thread`

`android-funcall-in-main-thread-list`

`android-get-current-activity`

`android-main-thread-p`

## 16.1 Delivering for Android

To use LispWorks in an Android project, the Android project needs three extra files:

### 1) `lispworks.jar`

This defines the support classes in the Java package `com.lispworks`. This file is part of the LispWorks distribution, and can be found in the `etc` directory in the LispWorks distribution:

```
(lispworks-file "etc/lispworks.jar")
```

You must add this file to your project. On Eclipse, it should be added to the build path, though you can also just copy it to the `libs` directory. On Android Studio 0.4.6 with the default configuration you can put it in `app/libs`.

2,3) A LispWorks heap and dynamic library. These two files are generated by `deliver-to-android-project`. Both have the same base name (default "LispWorks"). The library has "`lib`" before the base name and "`.so`" after it. The heap file name is the library name with the string "`.lwheap`" appended. The heap file needs to be in the "`assets`" sub-directory of the project, while the dynamic library needs to be in `armeabi-v7a` sub-directory of the jni libs directory of the project. For Eclipse, the jni libs directory is `libs` at the top level, and `assets` is at the top too, so the files are by default in:

```
assets/LispWorks.so.lwheap  
libs/armeabi-v7a/LispWorks.so
```

In Android Studio 0.4.6, the jni libs directory is `jnilibs`, and both it and the `assets` directory are in the "main" directory, so by default the files are in:

```
app/src/main/assets/LispWorks.so.lwheap  
app/src/main/jnilibs/armeabi-v7a/LispWorks.so
```

By default, `deliver-to-android-project` puts these files in these places, but note that on Eclipse if you have native libraries the default does not work. See full discussion in the entry for `deliver-to-android-project`.

The `lispworks.jar` file is required so that your Java IDE knows about classes in `com.lispworks`, so you need it while working on the Java code that interfaces with Lisp. The other two files are needed only when you actually build the project.

Once these three files are in place, the Android project can be built and installed like any Android project. To use LispWorks, the method `com.lispworks.Manager.init` must be called to initialize LispWorks. If *library-name* was passed to `deliver-to-android-project`, then `com.lispworks.Manager.init` must be called with a matching name, otherwise the default "LispWorks" is used. `com.lispworks.Manager.init` can be called at any point during the lifetime of the Android app.

`com.lispworks.Manager.init` is asynchronous, in other words by the time it returns Lisp is not ready yet. `com.lispworks.Manager.init` optionally

takes a `Runnable` argument, which is called when LispWorks is ready. Alternatively the method `com.lispworks.Manager.status` can be used to determine when LispWorks is ready. See the entry for `com.lispworks.Manager.init` for more details.

`com.lispworks.Manager.init` loads LispWorks and initializes it. Apart from standard initialization and starting multiprocessing, the startup function also initializes the Java interface using `init-java-interface`, passing it the appropriate arguments. That includes passing the keyword `:report-error-to-java-host`, which makes the function `report-error-to-java-host` invoke the user Java error reporters, and the keyword `:send-message-to-java-host` which makes the function `send-message-to-java-host` call the Java method `addMessage`. See Chapter 43, “Android Java classes and methods” for the details.

The startup functions also set up a global “last chance” internal debugger hook, which is invoked once the debugger actually gets called (after any hooks you set up like error handlers, debugger wrappers and `c1:*debugger-hook*`). The hook reports the error to the Java host (that is, invokes the user error reporters) and calls `c1:abort`. If you did not define a `c1:abort` restart, that will cause the current process to die, unless it is inside a call from Java, where it will cause this call to return. The return value is a zero of the correct type (see in “Direct calls” on page 206 and “Using proxies” on page 207).

Once initialization finished, if a function was passed to `deliver-to-android-project` as its *function* argument, it is invoked asynchronously, and then the `Runnable` which you passed to `com.lispworks.Manager.init` (if any) is invoked. From this point onwards, Lisp is ready to receive calls from Java, and can make calls into Java.

On Android when doing GUI operations it is essential to do them from the GUI thread, which is the main thread on Android. The functions `android-funcall-in-main-thread` and `android-funcall-in-main-thread-list` can be used to invoke a Lisp function on the main thread. To facilitate testing, these functions are also available on non-Android ports.

There is no proper debugger on Android itself, so it is important to ensure your code is working before delivering.

## 16.2 Directories on Android

On Android the temp directory that is used by default by `open-temp-file` and similar functions is the `cacheDir` of the application context. In principle the system can remove files from this directory when it needs disk space. The documentation for Android says that you should not rely too much on that, and avoid accumulating files in this directory.

LispWorks puts files with names starting with "lw" in this directory, so your code should avoid creating filenames starting with "lw".

`get-folder-path` can be used to find useful directories. `:appdata` for private directory, `:documents` for "user homedir" and `:common-appdata` for the external directory are the most useful keywords to pass. On Android `get-folder-path` can also be used to access the standard Android directories like the music and movies directories.

The function `cl:user-homedir-pathname` on Android returns the result of:

```
(sys:get-folder-path :documents)
```

## 16.3 The Othello demo for Android

The Othello demo is a simple Android app showing the basics of using LispWorks for Android Runtime. It is a full Android project that can be imported into an Android development environment, for example Eclipse with ADT and Android Studio.

The application plays the Othello game as an example of an application. When delivering "with Lisp" (see "Delivering LispWorks to the project" below), it also allows the user to type and evaluate Lisp forms. This is useful during development.

To try the demo, you need to do these steps:

1. Create an Android project containing the demo Android code.
2. Deliver the LispWorks application to it.
3. Build and install the application and run it.

These steps are described in detail in the following sections.

### 16.3.1 Creating an Android project

The Android project code is in `./OthelloDemo/`, which is the directory `examples/android/OthelloDemo` inside the LispWorks distribution. You need to make a project with this code.

The following sub-sections provide the detail for Eclipse and Android studio projects respectively.

#### 16.3.1.1 Othello project in Eclipse (with ADT)

This procedure was checked with ADT build: v22.6.2:

1. You need to have a workspace (corresponding to a directory), which may be completely empty.
2. Choose **File > Import** from the menubar to raise the **Import** dialog.
3. In the **Import** dialog expand **Android**, select **Existing Android Code Into Workspace** and click **Next**.
4. You should be in the **Import Projects** tab. Click **Browse....**
5. Navigate to the `examples/android/OthelloDemo` directory inside the LispWorks distribution directory, select it and press **Ok**.
6. Click **Select All** to ensure that the project is selected.
7. Select the **Copy projects into workspace** check button (below the list).
8. Click **Finish**.

The new project name defaults to "LispWorksRuntimeDemo", and this, relative to the workspace directory, is the project path that you will need to set the **\*project-path\*** to (below). You can change that before clicking **Finish**.

**Note:** if you get errors when trying to build, try:

1. Check that the Project build target is 3.0 or higher. Do: **Project > Preferences**, click **Android**, and it shows the list of targets available. Select the highest.
2. Try "cleaning": **Project > Clean**.

### 16.3.1.2 Othello project in Android studio

This procedure was checked with Android studio 0.4.6:

1. Inside Android studio, select **Import project...** either from the **Welcome to Android studio** dialog or from the **File** menu. That raises the **Select Gradle Project Import** dialog.
2. In the **Select Gradle Project Import** dialog, select the `examples/android/OthelloDemo` directory in the LispWorks distribution and press **OK**. That should raise a dialog called **Import Project from ADT (Eclipse Android)**.
3. Select a directory to put the project in and press **OK**. This is the "project path" that you will need to set the `*project-path*` variable to (below).
4. Leave all the default settings in the next page and press **Finish**.

### 16.3.2 Delivering LispWorks to the project

To deliver LispWorks, copy one of the build script files `deliver-android-othello.lisp` or `deliver-android-othello-with-lisp.lisp` from the `examples/android` directory in the LispWorks distribution. In the copied file change the value of the variable `*project-path*` to point to the directory of the project that you created above. For example:

```
(defvar *project-path* "~/my-workspace/LispWorksRuntimeDemo/")
```

You will then use your edited copy of the build script as the `-build` command line argument to LispWorks.

The Android delivery image is called `lispworks-7-1-0-arm-linux-android`. This must be run on an ARM architecture, currently that means ARM Linux or an emulator. To run this image under the QEMU emulator, use the script `examples/android/run-lw-android.sh`.

```
run-lw-android.sh -build /path/to/deliver-android-othello.lisp
```

See `deliver-to-android-project` for details.

If you cannot access the directories that you use in your project from the ARM machine:

1. Change \*project-path\* to some temporary directory, and add :no-sub-dir t to the call to `deliver-to-android-project`. For example, if you use `deliver-android-othello.lisp`, the call should be:

```
(deliver-to-android-project nil *project-path* 5 :no-sub-dir t)
```

This will create two files in the temporary directory called `libLisp-Works.so` and `LispWorks.so.lheap`.

2. Copy `libLispWorks.so` to the directory `libs/armeabi-v7a` inside your project, and copy `LispWorks.so.lheap` to the `assets` directory inside your project (assuming you are using Eclipse/ADT).

The two deliver scripts, `deliver-android-othello.lisp` ("without Lisp") and `deliver-android-othello-with-lisp.lisp` ("with Lisp") differ in what the application contains. The "with Lisp" script keeps a lot of Lisp in the application, and hence allows evaluation of Lisp forms when running on Android. The "without Lisp" script delivers at the maximum delivery level, and hence cannot evaluate forms. As a result the runtime image is much smaller.

### 16.3.3 Running the application

Once you have the project with the LispWorks files, you can build, install it on the device and run it as any other Android project. When it runs, It first shows a splash screen (the LispWorks splash screen image) and then the first screen displays an Othello board, where you can play against the computer (you play black), by touching the square where you want to add your piece.

The display has two elements in addition to the board:

- A small text view which displays the status of the game, and
- A checkbox **Computer Plays**, which controls whether the computer plays. When the computer does not play, the board is set for two players.

It also has a menu (which maybe partly displayed on the action bar), with these items:

**Restart**      Restart the game.

- Undo** Undo the last move. You can undo repeatedly to the beginning of the game.  
When the computer plays, each undo undoes to the state before your last move.  
When the computer does not play, it undoes one move.

When delivering "with Lisp" the menu also has these items:

- Lisp Panel** Takes you to the Lisp Panel screen, which allows you to evaluate Lisp forms. See below in the description of the Lisp Panel.

#### Command history

Takes you a list of the forms that that you evaluated. It is initialized by a few demo forms. See below about the **History** list.

- Othello Server** Raises a submenu with three items: **Java server, full proxy** and **lazy proxy**. Switching between these changes the mechanism by which Java calls into Lisp. The behavior of the game is exactly the same, only the output to the **Lisp Panel** or **Output** is different. This feature is for demonstrating different techniques of calling from Java to Lisp. See discussion of the code for details.

When delivering "without Lisp" the menu also has these items:

- Output** Takes you to the "output" screen.

#### 16.3.3.1 The Lisp Panel screen

The Lisp Panel contains a row of buttons, a text view for input, and the bottom is a text view for output. This screen is available only when delivering "with Lisp". When delivering "without Lisp", there is the Output screen instead.

The buttons are:

- Clear** Clears all the output from the output pane.

#### Evaluate the string

Send the current text in the input pane to Lisp by a direct call to `eval-for-android`.

`eval-for-android` is defined in (`example-edit-file "android/android-othello-user"`). It reads the string and evaluates it. If it is successful, it prints to the output pane the form, anything the form printed, and the result(s). If there is an error, it logs the error and prints the error message to the output pane.

<b>History</b>	Takes you to another screen which displays a list of the forms that were evaluated. The list is initialized by some forms which demonstrate some features of the multiprocessing on Android. See below in the section “Prepared forms”. Whenever you evaluate a form by pressing <b>Evaluate the string</b> , it adds the form to the history in the beginning of it. If the form matches exactly a form which is already in the list, the old item is removed.  In the history list, when you touch an item it is inserted into the input pane, and the application switches to the Lisp Panel. It does not evaluate the form at that point.  You can also reach the history list from the menu in the Othello screen.
<b>Bug form logs</b>	Invokes <code>com.lispworks.Manager.showBugFormLogs</code> . This shows another screen with a list of the logged errors displaying the error string for each item. Touching an item opens another screen with bug form log of this error.
<b>Clear logs</b>	Clears all the bug form logs, including removing the files.

The input pane below the buttons is just a passive text view, in which you can type Lisp forms, and evaluate by touching the **Evaluate the string** button.

The bottom part of the Lisp Panel, in the Output screen when delivering “without Lisp”, is the output pane. It prints the output of evaluation as above. It also prints whenever you touch a square in the Othello board. When the Full or Lazy proxy is used for communication, it also prints this fact.

### 16.3.3.2 Prepared forms

Initially, the **History** list contains the forms described below. When using forms, note that evaluating a form moves it to the top of the list. When you should evaluate more than one of these forms in order, you will need to look down the list for each one in turn.

The idea is that you can try these forms, and then modify them to check and perform things that you need to do when debugging your application.

Forms:

1.

```
(mp:ps)
```

Shows the Lisp processes. Initially there are at least the idle process and the GUI process which displays as "created by foreign code".

2.

```
(setq *computer-plays-waste-time-in-seconds* 2)
```

That causes the computer to pretend that it takes time to compute a move. When playing against the computer after setting this, you will see that after your move, the display says "Computer to play" for two seconds before it actually plays. Set **\*computer-plays-waste-time-in-seconds\*** back to **nil** to make it behave normally.

3.

```
(defun eval-and-print (form)
  (let ((res (eval form)))
    (lw-ji:send-message-to-java-host
      (princ-to-string res) :reset)))
```

Defines a function to be used by the next two forms. Note that it uses **send-message-to-java-host** to print, which comes in the output and works on any thread. When it is on the current thread it will end up printing before the printing of the evaluation, but on another thread it is random which output comes first.

4.

```
(eval-and-print '(mp:get-current-process))
```

Use the function defined above to print the process in the current thread. That is the GUI process.

5.

```
(mp:funcall-async 'eval-and-print '(mp:get-current-process))
```

Use the function `eval-and-print` defined above to print the process on which `funcall-async` executes the function. This will be one of the Background Execute processes.

6.

```
(progn
  (defun loop-executing-events ()
    (loop
      (let ((event (mp:process-wait-for-event)))
        (lw-ji:format-to-java-host "~%got event ~s" event)
        (let ((res (mp:general-handle-event event)))
          (lw-ji:format-to-java-host
            "~%Handling got ~s" res))))
    (setq loop-executing-events-process
      (mp:process-run-function "Loop Execute Events" ()
        'loop-executing-events)))
```

Create a process called "Loop Execute Events" and set `loop-executing-events-process` to it. The process has a process function `loop-executing-events` which read events and handles them using `process-wait-for-event` and `format-to-java-host`. It prints "got event <event>" and then "handling got <result of handling>". Note the usage of `format-to-java-host`, which prints to the output pane too (it actually calls `send-message-to-java-host`).

7.

```
(mp:process-send loop-executing-events-process '(mp:get-current-process))
```

Sends to the "Loop Execute Events" process (that started in the previous step) an event, which cause `get-current-process` to be called, and hence return the process. You should see "got event (MP:GET-CURRENT-PROCESS)" and "Handling got <process name>"

8.

```
(othello-user-change-a-square 5 2)
```

Changes square 5 (sixth from the left in the top row) to color 2 (black). This function is defined in (`example-edit-file "android/android-othello-user"`) and is part of the "interface" that the Lisp Othello code uses to tell Java to change the board.

**9.**

```
(mp:process-run-function
  "multiplier" ()
  #'(lambda()
      (setq *finish-multiply* nil)
      (dotimes (x 100)
        (sleep 1)
        (when *finish-multiply* (return))
        (lw-ji:format-to-java-host
          \"~%~d * ~d = ~d\"
          x x (* x x)))))
```

Starts a process that performs "a lengthy computation" (simulated by using `(sleep 1)`) and prints results while doing it. In each "step in the computation" (the `cl:dotimes` iteration) it prints the square of the iteration number. To stop it, evaluate the next form.

**10.**

```
(setq *finish-multiply* t)
```

Tell the "multiplier" process (see above) to stop.

**11.**

```
(mp:process-run-function
  "Error"
  () #'(lambda () (open "junk;;file::name")))
```

Starts another process that gets an error (because the argument to `cl:open` is an illegal pathname). It prints that it got the error, and you can use the **Bug form logs** button to look at the bug form log.

**12.**

```
(raise-alert-dialog
  "What do you want to eat?" +
:ok-title "Chicken"
:ok-callback '(raise-alert-dialog "Here is some chicken") +
:cancel-title "Salad"
:cancel-callback '(raise-alert-dialog "We do not have salad"))
```

Raises an alert dialog using `raise-alert-dialog` which is defined in `dialog.lisp`. Note that this works because the `LispPanel` class uses `com.lispworks.Manager.setCurrentActivity` to set the current activity.

### 13.

```
(raise-a-toast "Bla Bla Bla" :gravity :left)
```

Raises an Android "toast" at the middle of the left side, using `raise-a-toast` which is defined in `toast.lisp`.

#### 16.3.4 Lisp interface usage in the Java code

The Othello Demo Java code is in the package `com.lispworks.example.othellodemo`. LispWorks interfaces in Java are all in the package `com.lispworks`. The methods appear in full, to make it is easy to see where there is a call to the LispWorks interface.

##### 16.3.4.1 Class Othello

`Othello` is a subclass of `Activity` that displays the screen with the Othello board. The display is all in standard Java. The board is made of a grid of 64 `ImageView` panes, each one displaying one of three images (blank, white, black). Each view has an `OnClickListener` (`SquareListener`) that remembers its index and passes it when clicked.

The Java code does not know anything about the game that is being played, and does not keep a record of the state of the game. That is all done in Lisp.

The Java code processes user gestures concerning the game (touching the board, and touching any of the buttons and items `Computer plays`, `undo move`, `restart`) by calling methods on an object that implements the nested interface `OthelloServer`, which is kept in `mOthelloServer`. The object can be either a Lisp proxy, or of the nested class `JavaOthelloServer`. All of these objects do exactly the same thing (calling the Lisp functions defined in `(example-edit-file "misc/othello")`), and the purpose of having all these options is to demonstrate different techniques to call into Lisp. There is also a nested class `ErrorOthelloServer` in case LispWorks does not work, which displays the error. `mOthelloServer` is set by the method `setupServer`.

The nested class `JavaOthelloServer` is plain Java with methods that call into Lisp using the “Direct calls” interface (`com.lispworks.LispCalls.callIntv` and `com.lispworks.LispCalls.callVoidv`). This has the advantage that on the Lisp side all you have to do is to ensure that the functions are not shaken, which you can do with `hcl:deliver-keep-symbols` (see the *Lisp-Works Delivery User Guide*). It has the disadvantage that you hardwire Lisp function names in Java (though the names can be variables too).

The other two possible implementations of the `OthelloServer` are Lisp proxies which are defined in Lisp (in `examples/android/android-othello-user.lisp`). See the discussion of the Lisp code for more details. The code in `setupServer` demonstrates two techniques of using the proxy definitions: either calling a Lisp function that makes a proxy (using `com.lisp-works.LispCalls.callObjectv` to call `create-lisp-othello-server`), or using `com.lispworks.LispCalls.createLispProxy` with the name of the proxy definition (`lisp-othello-server-lazy`) to create a proxy.

To actually respond to moves, the `othello` class exports 3 methods (“`updateState`”, “`signalBadMove`” and “`change`”) which are called directly from Lisp to change the board and the status text.

When an `othello` instance is created, it calls `setupAndInit` to do anything with Lisp (mainly call `mOthelloServer.init`). Before doing anything that may interact with Lisp, it checks the status of Lisp using `com.lisp-works.Manager.status`. If Lisp is not ready and there was no error, it calls `com.lispworks.Manager.init` to initialize LispWorks, passing it a `Runnable` that with call `setupAndInit` again to actually do the initialization. In the Demo the Lisp side will already be initialized, because it is done by the `Lisp-WorksRuntimeDemo` activity, but the `othello` class avoids relying on it.

When LispWorks is ready, `setupAndInit` sets up the server by calling `setUpServer` and initializes the game by calling `mOthelloServer.init`.

If there is an error, `setupAndInit` gets the error details using `com.lisp-works.Manager.mInitErrorString`, and `com.lispworks.Manager.init_result_code` and adds a message, set `mOthelloServer` to `ErrorOthelloServer`, and then shows the Lisp Panel which will be displaying the error.

There is also an `onCreateOptionsMenu` method which checks whether Lisp is working and can evaluate forms (using `LispPanel.canEvaluate`), and accordingly decides which menu to use.

#### 16.3.4.2 Class LispPanel

`LispPanel` is a subclass of `Activity` that displays the Lisp panel, or just the output when delivering "without Lisp" (see "Delivering LispWorks to the project" on page 229).

The main purpose of the Lisp Panel is to evaluate Lisp forms, which it does by calling the Lisp function `eval-for-android` using `com.lispworks.LispCalls.callIntv`. That can work only if `eval-for-android` is defined, so `LispPanel` has a method `canEvaluate` that works by checking if `eval-for-android` is defined using `com.lispworks.LispCalls.checkLispSymbol`. If `eval-for-android` is fbound, `LispPanel` displays in full, otherwise it shows only output `TextView`.

`LispPanel` is also responsible for displaying messages in its output `TextView`. To achieve that, it uses `com.lispworks.Manager.setTextView`. Once it sets the `TextView`, all calls to `com.lispworks.Manager.addMessage` and calls to the Lisp functions `send-message-to-java-host` and `format-to-java-host` put their output in this `TextView`.

Other usage of the `com.lispworks` package in `LispPanel` are:

- `com.lispworks.Manager.setErrorReporter` to set an error reporter. Since the Lisp application does not set `cl:*debugger-hook*`, uncaught errors will end up calling this reporter.
- Calls to `com.lispworks.Manager.showBugFormLogs` to show bug form logs, and `com.lispworks.Manager.clearBugFormLogs` to clear them.
- Calls to `com.lispworks.Manager.setCurrentActivity` in `onResume` and `onPause` to allow Lisp code to raise dialogs when `LispPanel` is visible. This is needed to allow the `raise-alert-dialog` form to work.

#### 16.3.4.3 Class MyApplication

`MyApplication` is not actually used in the demo. It is a demonstration of how to initialize LispWorks when the application starts, by calling `com.lisp-`

`works.Manager.init` in the `onCreate` of the application. The demo itself does not use this mechanism. Instead the `SplashScreen` activity does it, and the `Othello` activity also checks using `com.lispworks.Manager.status`, and if LispWorks needs initializing does it.

#### 16.3.4.4 Class LispWorksRuntimeDemo

Display a splash screen and initialize the Lisp side, by checking `com.lispworks.Manager.status` and using `com.lispworks.Manager.init` if needed. The purpose of this class is just to give an example of displaying a splash screen while initializing Lisp. It is not really needed, because the `Othello` class checks too (in `setupAndInit`). On Eclipse the name of this class is the default project name.

#### 16.3.4.5 Class History

A simple class to display Lisp forms. Does not do anything related to Lisp.

#### 16.3.4.6 Class SquareLayout

A simple class to make a square layout for displaying the `Othello` board. Does not do anything related to Lisp.

### 16.3.5 Java and Android interface in the Lisp code

The file

```
(example-edit-file "misc/othello")
```

is a generic implementation of the playing Othello part, and has nothing to do with Java or Android.

The Lisp code that interacts with Java and Android to play Othello and evaluate the forms is in

```
(example-edit-file "android/android-othello-user")
```

The Java callers to update the game are defined by a `define-java-caller` form. All these methods need to be called on the GUI thread (because they interact with GUI elements), so the actual functions that are called from the

Othello code are defined to call the Java callers using `android-funcall-in-main-thread`.

The function `eval-for-android` is what the Java code uses to evaluate Lisp forms. The function has no Java-specific features, but it has error handling and binding of some of the top-level variables like `c1:*` to make it more usable in repeated calls from "outside".

The code also defines two proxy definitions that implement the `othello.OthelloServer` interface which responds to user gestures. To demonstrate the various features of proxies, there are two definitions which achieve exactly the same thing. The full proxy definition (`lisp-othello-server-full`) specifies functions for all the methods that the interface defines. The lazy (programmer) proxy definition does not define any method. Instead it has a default function that decides what to do based on the method name.

The two files

```
(example-edit-file "android/dialog")
```

and

```
(example-edit-file "android/toast")
```

define the functions `raise-alert-dialog` and `raise-a-toast` respectively, to demonstrate using Android code directly from Lisp. See the comments in these files.

# 17

---

## iOS interface

To build an application using LispWorks for iOS Runtime, you need an Xcode project to implement the main function of the application. CAPI is not currently supported on iOS, so any GUI part will need to be written in Objective-C using Xcode too.

### 17.1 Delivering for iOS

The Lisp part of the application needs to be delivered using one of four special images:

- `lispworks-7-1-0-x86-darwin-ios` and `lispworks-7-0-0-amd64-darwin-ios` which build runtimes for the iOS Simulator, 32-bit and 64-bit, running on Mac OS X, or
- `lispworks-7-1-0-arm-linux-ios` and `lispworks-7-0-0-arm64-linux-ios` which build runtimes for the real iOS device, 32-bit and 64-bit. To do this, you run the QEMU emulator on Mac OS X and tell it to run the `lispworks-7-1-0-arm-linux-ios` or `lispworks-7-0-0-arm64-linux-ios` image.

There is an example script `examples/ios/run-lw-ios.sh` which can be used to invoke all of these images in sequence with the same command line arguments.

These images do not contain the GUI part of LispWorks, but do contain all the non-GUI parts.

There are no iOS-specific Lisp functions required to build the Lisp part of an application: you use `deliver` in the normal way. The only difference compared to a desktop application is that the *file* passed to `deliver` should have a ".o" extension and the generated file will be an iOS object file that must be linked with the other parts of the application using Xcode. Generation of shared libraries is not supported (this is a limitation of iOS).

To include the delivered object file in an Xcode project, add the file to the project using the **File > Add files to <project>...** menu item. Xcode should detect this as a file of type "Object Code".

If you want to run the same Xcode project with both the iOS Simulator and a real device or build for 32-bit and 64-bit devices then you can conditionalize the filename passed to `deliver` to create four different files. For example,

```
(deliver 'init-othello-server
         (merge-pathnames
           (format nil "OthelloDemo/OthelloServer-~A.o"
                  #+arm "armv7"
                  #+arm64 "arm64")
                  #+x86 "i386")
                  #+x86-64 "x86_64")
         *project-path*)
0
:keep-symbols '(othello-server))
```

Then add `OthelloServer-armv7.o`, `OthelloServer-arm64.o`, `OthelloServer-i386.o` and `OthelloServer-x86_64.o` to the Xcode project. Building the project will result in warnings such as

```
ld: warning: ignoring file
/Users/developer/Documents/OthelloDemo/OthelloDemo/OthelloServer-
armv7.o, file
was built for armv7 which is not the architecture being linked
(i386):
/Users/developer/Documents/OthelloDemo/OthelloDemo/OthelloServer-
armv7.o
```

These warnings can be ignored.

## 17.2 Initializing LispWorks

In order to use Lisp code within an application built using Xcode, the main function of the application must call `LispWorksInitialize`. For example, `main` might be implemented like this:

```
#import "LispWorks.h"

int main(int argc, char *argv[])
{
    if (!LispWorksInitialize(argc, argv)) abort();

    @autoreleasepool {
        return UIApplicationMain(argc, argv, nil,
        NSStringFromClass([OthelloAppDelegate class]));
    }
}
```

`LispWorksInitialize` is automatically included in the object file generated by `deliver`. The file `LispWorks.h` can be found in the `examples/ios/OthelloDemo/OthelloDemo/` directory of the LispWorks installation and should be copied into the Xcode project.

## 17.3 Using Objective-C from Lisp

LispWorks calls the function `objc:ensure-objc-initialized` when it starts the iOS runtime, so there is no need for you to call it.

For other details, see the *LispWorks Objective-C and Cocoa Interface User Guide and Reference Manual*.

## 17.4 Limitations of the iOS Runtime

There are some limitations that iOS imposes that affect the LispWorks for iOS Runtime.

- Compiled code cannot be generated, so `c1:compile` cannot be called at run time.
- Shared libraries cannot be loaded dynamically, so `fli:register-module` cannot be used. Instead, add references to any required frameworks in the Xcode project.

## 17.5 The Othello demo for iOS

The Othello demo is a simple iOS app showing the basics of using LispWorks for iOS Runtime. It contains an Xcode project to run the GUI and some Lisp source code to play the game.

To try the demonstration, see the file

```
(example-edit-file "ios/README.txt")
```

### 17.5.1 Notes about the Xcode project

The Xcode project in `examples/ios/OthelloDemo/` has a standard layout, with the class `OthelloAppDelegate` defined in

```
(example-edit-file "ios/OthelloDemo/OthelloDemo/
OthelloAppDelegate.m")
```

implementing the `UIApplicationDelegate` protocol.

The file

```
(example-edit-file "ios/OthelloDemo/OthelloDemo/main.m")
```

initializes LispWorks by calling `LispWorksInitialize` and then runs the application main loop using the `OthelloAppDelegate`.

The application has two storyboards (`MainStoryboard_iPhone` and `MainStoryboard_iPad`) which display a Tab Bar allowing you to switch between an Othello game and a Lisp evaluation pane.

### 17.5.2 The Othello game

The Othello game is displayed by the `Othello` scene and contains an Othello board (the `boardView` outlet), a few buttons on a toolbar and a label showing the state of the game (the `stateView` outlet).

The scene is controlled by the class `OthelloViewController`, defined in

```
(example-edit-file "ios/OthelloDemo/OthelloDemo/
OthelloViewController.m")
```

The 64 tiles on the board are represented by `UIImageView` objects, created dynamically in the `viewDidLoad` method. The contents of the tiles are the

images "empty", "white" and "black" which are loaded from the `Images.xcassets` asset catalog. The `viewDidLoad` method also creates an instance of the class `OthelloServer`, which is implemented in Lisp (see "Notes about the Lisp code" on page 246).

The tiles in the board are dynamically positioned by the `viewDidLayoutSubviews` method.

The action methods `restartOthello:` and `undoMove:` are connected to the toolbar buttons in the storyboards and call into the Lisp code to update the game.

The action method `playUISquare:` is triggered when the user touches a square on the board (see `viewDidLoad`) and calls into the Lisp code to play that square.

The methods `changeOthelloSquare:, updateStateString:` and `signalBadMove` are called by the Lisp code to modify the GUI.

### 17.5.3 The Lisp evaluation pane

The Lisp evaluation pane is displayed by the `Lisp Panel` scene and contains a text field for entering a Lisp form (the `formInputView` outlet), a text field to display the evaluation results (the `textOutputView` outlet) and toolbar.

The scene is controlled by the class `LispPanelViewController`, defined in

```
(example-edit-file "ios/OthelloDemo/OthelloDemo/
LispPanelViewController.m")
```

The action methods `evaluate:, clearTextOutput:` and `showHistory:` are connected to the toolbar buttons in the storyboards.

The **History** button pops up a history of the forms entered so far. This is displayed by the `History Table` scene controlled by `HistoryTableViewController`, defined in

```
(example-edit-file "ios/OthelloDemo/OthelloDemo/
HistoryTableViewController.m")
```

and communicates back to the `LispPanelViewController` using the `HistoryTableViewControllerDelegate` protocol.

The `keyboardWasShown:` and `keyboardWillBeHidden:` notification methods resize the `textOutputView` to avoid the on-screen keyboard.

The method `appendTextOutputString:` is called by Lisp code to update the `textOutputView`.

#### 17.5.4 Notes about the Lisp code

The Lisp code triggered by the GUI is in the file

```
(example-edit-file "ios/ios-othello-user")
```

and uses the shared Othello logic in

```
(example-edit-file "misc/othello")
```

The function `init-othello-server` is the main entry point of the Lisp code and is called when `LispWorksInitialize` is called from `main.m`. It initializes the LispWorks Objective-C interface and creates a helper object (`lispworks-main-threads-funcalls-object`) used by `invoke-in-main-thread` for making Lisp calls in the main thread of the application.

The Lisp code implements an Objective-C class `othelloServer` using the Lisp class `othello-server`. This class implements the methods `initWithViewController` for initialization and `initOthello`, `playSquare:` and `undoMove` for the Othello game GUI code to call into Lisp in response to user gestures.

The Lisp code also implements the functions `othello-user-change-a-square`, `othello-user-update-state-string`, `othello-user-signal-bad-move` and `othello-user-print-diagnostics-message` which the shared Othello logic calls to update the GUI. Most of these functions call methods on the `OthelloViewController` object, taking care to invoke them in the main (GUI) thread of the application. This thread switching is needed because the Othello logic plays the game in a background thread to avoid hanging the GUI while considering its move (see `perform-computer-play` in `examples/misc/othello.lisp`).

Finally, the Lisp code implements an Objective-C class `LispPanelServer` using the Lisp class `lisp-panel-server`, with a method `evaluate:` to evaluate a Lisp form. This `evaluate:` method is called by the `evaluate:` action method in `LispPanelViewController`.

## 17.6 The Mobile GC

The Mobile GC is a 64-bit GC that is written to run on 64-bit iOS (we are also considering using it for 64-bit Android). When LispWorks is delivered for 64-bit iOS, the "saved image" (the code in the object file that delivery creates) switches automatically to use the Mobile GC. Thus normally you do not need to know anything about the Mobile GC, and if your application has moderate memory requirements (a few tens of megabytes of live allocation at run time), then there is a good chance that you do not need to do anything about memory management.

However, it is useful in general to create a log file of the activity of the application (at least during development), and to include the output of periodic calls to `(room)` or `(room n11)` in this log, which will give you some idea of the memory behavior of your application. In particular, if the "Total allocated" that is reported in the last line of `(room)` (which is the only line in `(room n11)`) approaches 100 MB then you may want to look at memory management. Note that is only for a mobile device: Desktop applications can grow much larger without a problem.

The main problem that you may encounter in the Mobile GC are GCs of generation 2 causing noticeable delays (on the order of 1 second, depending on the size of the application and the hardware). Depending on the application, such delays may or may not be an issue, but for most GUI applications you should ensure they do not happen too frequently. In this situation you should consult "Preventing/reducing GC of generation 2" on page 159.

You may also consider implementing a response to low memory warning from the OS. All applications can benefit a little by calling `reduce-memory` with `n11` or `0` or `1` at that point, but for most applications the benefit is minimal. If most of the live memory in your application contains caches that can be freed and recreated again without much loss in performance, you may be able to get significant improvement by implementing a low memory warning response that clears the caches. Consult "Response to low memory" on page 158 for details.

The output of `room` and the results of related functions are different when the Mobile GC is used. If you want to understand this output better, consult "Mobile GC technical details" on page 154.

---

# The Metaobject Protocol

LispWorks CLOS essentially supports the metaobject protocol described in chapters 5 & 6 of *The Art of the Metaobject Protocol* (Kiczales, des Rivières & Bobrow, The MIT Press, 1991). Throughout the LispWorks documentation, “AMOP” refers to this book. The relevant chapters are available in the LispWorks IDE via the menu command **Help > Manuals > CLOS Metaobject Protocol**.

All the LispWorks MOP symbols are in the `clos` package.

There are some discrepancies between LispWorks and AMOP, which are described in this chapter, which also describes some common problems encountered by programmers using the MOP.

## 18.1 Metaobject features incompatible with AMOP

### 18.1.1 Instance Structure Protocol

The generic functions implementing slot access are like those described in AMOP, except that each takes a *slot-name* argument rather than a slot definition object, and the primary methods are therefore specialized differently.

For details, see `slot-boundp-using-class`, `slot-value-using-class` and `slot-makunbound-using-class`.

**Note:** by default, standard slot accessors are optimized to not call `slot-value-using-class`. This can be overridden with the `:optimize-slot-access` class option. See the second definition of `virtual-metaclass` below for an example of the use of this.

`standard-instance-access` is not supported as defined in AMOP. Note that there is an internal function of the same name, but this is not optimal. Also, `funcallable-standard-instance-access` is not supported. An alternative for fast instance access is to use the `:optimize-slot-access` class option.

### 18.1.2 Method Metaobjects

`standard-reader-method`, `standard-accessor-method` and `standard-writer-method` all have a required `:slot-name` initarg, rather than a `:slot-definition` initarg as specified in AMOP.

**Compatibility note:** in LispWorks 4.3 and previous versions, `accessor-method-slot-definition` was not implemented. This is implemented in the current version.

### 18.1.3 Method Lambdas

LispWorks `make-method-lambda` is not AMOP-compatible. It takes separate `lambda-list` and `body` arguments, and the returned `lambda` form is different to that specified in AMOP (see “Method Functions” on page 250 below).

LispWorks does not support user defined methods for the generic function `make-method-lambda`.

### 18.1.4 Method Functions

LispWorks method functions take the same arguments as the method itself, whereas in AMOP they take a list of arguments and a list of next methods.

### 18.1.5 EQL specializers

`eql-specializer`, `eql-specializer-object` and `intern-eql-specializer` are not implemented.

`eql` specializers in LispWorks are lists.

### 18.1.6 Generic Function Invocation Protocol

`compute-applicable-methods-using-classes` is not implemented.

`compute-discriminating-function` is implemented and returns the discriminator but:

- It does not use `compute-applicable-methods-using-classes` since LispWorks does not have that function.
- It does not call `compute-applicable-methods`.

Moreover `add-method` does not call `compute-discriminating-function` because this would be inefficient when doing multiple calls to `add-method`. Instead, `compute-discriminating-function` is called when the generic function is called.

### 18.1.7 Method combinations

`method-combination` objects do not contain the arguments, merely the type. There is a single `method-combination` object per type.

Therefore the value returned by `generic-function-method-combination`, and the default value of the `:method-combination` initarg, and the `:method-combination` argument processed by `ensure-generic-function-using-class` are specific only to the type of the method combination.

Also, `find-method-combination` is not implemented.

### 18.1.8 Compatible metaclasses

The AMOP defines that the standard primary method for `validate-superclass` should return true if the class of one of the arguments is `standard-class` and the class of the other is `funcallable-standard-class`.

In LispWorks, objects of these metaclasses are not completely compatible, so `validate-superclass` will return false in these cases.

Beware that defining a class that mixes `standard-class` and `funcallable-standard-class` can lead to inconsistencies with the predicate `functionp`, the type `function` and the class `function`.

### 18.1.9 Inheritance Structure of Metaobject Classes

`funcallable-standard-object` is implemented as defined in AMOP, except that its class precedence list has direct superclasses

`(function standard-object)`

rather than

`(standard-object function)`

so that LispWorks is compliant with the ANSI Common Lisp rules.

For details, see `funcallable-standard-object`, page 494.

## 18.2 Metaobject features additional to AMOP

### 18.2.1 Computing the effective method function

The generic function `compute-effective-method-function-from-classes` is called by LispWorks to compute the effective method function. You can add methods to implement non-standard behavior for your own classes of generic functions.

## 18.3 Common problems when using the MOP

### 18.3.1 Inheritance across metaclasses

Usually an inherited class is of the same metaclass as the parent class.

For other kinds of inheritance, you need to define a method on `validate-superclass` which returns true when called with the respective metaclasses. For example:

```
(defclass mclass-1 (standard-class)
  ())

(defclass mclass-2 (standard-class)
  ())

(defclass a ()
  ()
  (:metaclass mclass-1))

(defmethod validate-superclass
  ((class mclass-2)
   (superclass mclass-1))
  t)

(defclass b (a)
  ()
  (:metaclass mclass-2))
```

Without the `validate-superclass` method, the last form signals an error because `mclass-1` is an invalid superclass of `mclass-2`.

### 18.3.2 Accessors not using structure instance protocol

By default, `defclass` creates optimized standard accessors which do not call `slot-value-using-class`.

This optimization is controlled by the `defclass` option `:optimize-slot-access`, which defaults to `t`.

There is an illustration of this effect of `:optimize-slot-access` in the example below.

### 18.3.3 The MOP in delivered images

Issues with MOP code that occur only in delivered LispWorks images are documented in the section “Delivery and the MOP” in the *LispWorks Delivery User Guide*.

## 18.4 Implementation of virtual slots

This is an implementation of virtual slots with readers, writers and which also allow access by `slot-value`.

```

;; ----- Virtual Slots -----
(in-package "CL-USER")

;; Metaclass of objects that might contain virtual slots.

(defclass virtual-metaclass (standard-class)
  ()
  )

;; Mixin metaclass for virtual slots and methods to make them
;; appear virtual.

(defclass virtual-slot-definition
  (standard-slot-definition)
  ((function :initarg :function
             :accessor virtual-slot-definition-function)))
  )

(defmethod slot-definition-allocation
  ((slotd virtual-slot-definition))
  :virtual)

(defmethod (setf slot-definition-allocation)
  (allocation (slotd virtual-slot-definition))
  (unless (eq allocation :virtual)
    (error "Cannot change the allocation of a ~S"
          'virtual-direct-slot-definition))
  allocation)

;; Class of direct virtual slots and methods to construct them
;; when appropriate.

(defclass virtual-direct-slot-definition
  (standard-direct-slot-definition
   virtual-slot-definition)
  ()
  )

;; Called when the class is being made, to choose the metaclass of
;; a given direct slot. It should return the class of slot
;; definition required.

(defmethod clos:direct-slot-definition-class
  ((class virtual-metaclass) &rest initargs)
  ;; Use virtual-direct-slot-definition if appropriate.
  (if (eq (getf initargs :allocation) :virtual)
      (find-class 'virtual-direct-slot-definition)

```

```

        (call-next-method)))

;; Called when the defclass is expanded, to process a slot option.
;; It should return the new list of slot options, based on
;; already-processed-options.

(defmethod clos:process-a-slot-option
    ((class virtual-metaclass) option value
     already-processed-options slot)
  ;; Handle the :function option by adding it to the
  ;; list of processed options.
  (if (eq option :function)
      (list* :function value already-processed-options)
      (call-next-method)))

;; Class of effective virtual slots and methods to construct
;; them when appropriate.

(defclass virtual-effective-slot-definition
    (standard-effective-slot-definition
     virtual-slot-definition)
  ()
  )

;; Called when the class is being finalized, to choose the
;; metaclass of a given effective slot.  It should return the
;; class of slot definition required.

(defmethod clos:effective-slot-definition-class
    ((class virtual-metaclass) &rest initargs)
  ;; Use virtual-effective-slot-definition if appropriate.
  (let ((slot-initargs (getf initargs :initargs)))
    (if (member :virtual-slot slot-initargs)
        (find-class 'virtual-effective-slot-definition)
        (call-next-method)))

(defmethod clos:compute-effective-slot-definition
    ((class virtual-metaclass)
     name
     direct-slot-definitions)
  ;; Copy the function into the effective slot definition
  ;; if appropriate.
  (let ((effective-slotted (call-next-method)))
    (dolist (slotted direct-slot-definitions)
      (when (typep slotted 'virtual-slot-definition)
        (setf (virtual-slot-definition-function effective-slotted)

```

```

(virtual-slot-definition-function slotd))
  (return)))
effective-slotd))

;; Underlying access methods for invoking
;; virtual-slot-definition-function.

(defmethod clos:slot-value-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :get
                 object)
        (call-next-method)))))

(defmethod (setf clos:slot-value-using-class)
  (value (class virtual-metaclass) object slot-name)
  (format t "~% setf slot : ~A" slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :set
                 object
                 value)
        (call-next-method)))))

(defmethod clos:slot-boundp-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :is-set
                 object)
        (call-next-method)))))

(defmethod clos:slot-makunbound-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :unset
                 object)
        (call-next-method)))))

```

```

          object)
(call-next-method)))))

(defmethod clos:slot-exists-p-using-class
  ((class virtual-metaclass) object slot-name)
(or (call-next-method)
  (and (find slot-name (class-slots class)
             :key 'slot-definition-name)
       t)))

;; Example virtual slot which depends on a real slot.
;; Compile this separately after the virtual-metaclass etc.

(defclass a-virtual-class ()
  ((real-slot :initarg :real-slot :accessor real-slot
              :initform -1)
   (virtual-slot :accessor virtual-slot
                 :initarg :virtual-slot
                 :allocation :virtual
                 :function
                 'a-virtual-class-virtual-slot-function))
  (:metaclass virtual-metaclass))

(defun a-virtual-class-virtual-slot-function
  (key object &optional value)
  (ecase key
    (:get (let ((real-slot (real-slot object)))
            (if (<= 0 real-slot 100)
                (/ real-slot 100.0)
                (slot-unbound (class-of object)
                              object
                              'virtual-slot))))
    (:set (setf (real-slot object) (* value 100))
          value)
    (:is-set (let ((real-slot (real-slot object)))
               (<= real-slot 100)))
    (:unset (setf (real-slot object) -1))))
;; ----- Virtual Slots -----

```

Compile the code above. Then make an object and access the virtual slot:

```

CL-USER 1 > (setf object (make-instance 'a-virtual-class))
#<A-VIRTUAL-CLASS 2067B064>

CL-USER 2 > (setf (virtual-slot object) 0.75)

      setf slot : VIRTUAL-SLOT
0.75

CL-USER 3 > (virtual-slot object)
0.75

CL-USER 4 > (real-slot object)
75.0

```

Note that when you call `(setf real-slot)` there is no output since `(setf clos:slot-value-using-class)` is not called. Compare with `(setf virtual-slot)`.

```

CL-USER 5 > (setf (real-slot object) 42)
42

```

Redefine `a-virtual-class` with `:optimize-slot-access nil`:

```

CL-USER 6 > (defclass a-virtual-class ()
               ((real-slot :initarg :real-slot
                           :accessor real-slot
                           :initform -1)
                (virtual-slot :accessor virtual-slot
                           :initarg :virtual-slot
                           :allocation :virtual
                           :function
                           'a-virtual-class-virtual-slot-function))
               (:metaclass virtual-metaclass)
               (:optimize-slot-access nil))

Warning: (DEFCLASS A-VIRTUAL-CLASS) being redefined in LISTENER
(previously in H:\tmp\vs.lisp).
Warning: (METHOD REAL-SLOT (A-VIRTUAL-CLASS)) being redefined in
LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD (SETF REAL-SLOT) (T A-VIRTUAL-CLASS)) being
redefined in LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD VIRTUAL-SLOT (A-VIRTUAL-CLASS)) being redefined
in LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD (SETF VIRTUAL-SLOT) (T A-VIRTUAL-CLASS)) being
redefined in LISTENER (previously in H:\tmp\vs.lisp).
#<VIRTUAL-METACLASS A-VIRTUAL-CLASS 21AD908C>

```

Now the standard accessors call `slot-value-using-class`, so we see output when calling `(setf real-slot)`

```
CL-USER 7 > (setf (real-slot object) 42)

  setf slot : REAL-SLOT
  42
```

# 19

---

# Multiprocessing

LispWorks supports threads for running computations in parallel. The programming environment, for example, makes extensive use of this mechanism to create separate threads for the various tools.

On Microsoft Windows, Mac OS X, Linux, x86/x64 Solaris, FreeBSD and AIX, LispWorks multiprocessing uses native threads and supports Symmetric Multiprocessing (SMP). The implementation is referred to as "SMP LispWorks" where relevant.

On other platforms LispWorks uses a single native thread and implements user level threads. The implementation is referred to as "non-SMP LispWorks" where relevant.

In SMP LispWorks, Lisp processes (as reported by the Lisp function `ps`) are Operating System threads. These do not necessarily correspond to what system tools show you, for example in Microsoft Windows the Activity monitor shows OS processes, including exactly one for each running LispWorks image.

## 19.1 Introduction to processes

A process (sometimes called a thread) is a separate execution context. It has its own call stack and its own dynamic environment.

A process can be in one of three different states: *running*, *waiting*, and *inactive*. When a process is *waiting*, it is still active, but is waiting for the system to wake it up and allow its computation to restart. A process that is *inactive* has stopped, because it has an arrest “reason”.

For a process to be active (that is, running or waiting), it must have at least one run reason and no arrest reasons. If, for example, it was necessary to temporarily stop a process, it could temporarily be given an arrest reason. However the arrest reason mechanism is not commonly used in this manner.

The process that is currently executing is termed “the current process”. The function `get-current-process` gets the current process, and is the preferred way of doing so. The variable `*current-process*` is normally bound to the same process, except inside a wait function when it is called by the scheduler.

The current process continues to be executed until either it becomes a waiting process by calling a Process Wait function as described in “Process Waiting and communication between processes” on page 280, or it allows itself to be interrupted by calling `process-allow-scheduling` (or its current timeslice expires and it involuntarily relinquishes control).

In SMP LispWorks all processes that are not waiting are running as far as LispWorks is concerned, and are scheduled by the operating system to the available CPUs.

In non-SMP LispWorks, the system runs the waiting process with the highest priority. If processes have the same priority then the system treats them equally and fairly. This is called round robin scheduling.

The simplest way to create a process is to use `process-run-function`. This creates a process with the specified name which commences by applying the specified function to arguments. `process-run-function` returns immediately and the newly created process runs concurrently.

## 19.2 Processes basics

### 19.2.1 Creating a process

To create a new process, use `process-run-function`.

A process can exit either by returning from the process function or by calling `current-process-kill`.

### 19.2.2 Finding out about processes

The system initializes a number of processes on startup. These processes are specified by `*initial-processes*`.

The current process is obtained by `get-current-process`. A list of all the current processes is returned by `list-all-processes` and the number of them is returned by `processes-count`. The function `ps` is analogous to the UNIX command `ps`, and returns a list of the processes in the system, ordered by priority.

To find a process when you know its name, use `get-process`. To find the name, when you have the process, use `process-name`. The variable `*process-initial-bindings*` specifies the variables that are initially bound in a process.

### 19.2.3 Multiprocessing

To start multiprocessing, use `initialize-multiprocessing`. This function does not return until multiprocessing has terminated.

It is not necessary to use `initialize-multiprocessing` when the LispWorks IDE is already running. Note that, on Windows, Mac OS X, Linux, x86/x64 Solaris, FreeBSD and AIX, the LispWorks images shipped do start the IDE. If you create an image which does not start the IDE, by using the `:environment nil` argument to `save-image`, then multiprocessing can be started in this new image as described below.

#### 19.2.3.1 Starting multiprocessing interactively

You can call `initialize-multiprocessing` from the REPL interface, which generates a default Listener process if no other processes are specified by `*initial-processes*`.

### 19.2.3.2 Multiprocessing on startup

There are three ways to make a LispWorks executable start multiprocessing on startup.

1. Use the `-multiprocessing` command line argument
2. Save an image which starts multiprocessing by doing

```
(save-image "mp-lispworks"
  :restart-function 'mp:initialize-multiprocessing)
```

3. Use delivery to create the executable and pass the argument `:multiprocessing t` to `deliver`. The delivery function will be called automatically in a new process. See the *LispWorks Delivery User Guide* for more details.

LispWorks dynamic libraries always start multiprocessing on startup. See “Multiprocessing in a dynamic library” on page 195 for more information.

In all cases, `*initial-processes*` can be used to control which processes are created on startup, as described in “Running your own processes on startup” on page 264.

**Note:** On Windows, Mac OS X, Linux, x86/x64 Solaris, FreeBSD and AIX you cannot save a LispWorks image with multiprocessing running.

### 19.2.3.3 Running your own processes on startup

`*initial-processes*` is a list of lists. Each list is used by the system as a set of arguments to `process-run-function`. During initializing multiprocessing, the system does this:

```
(dolist (x mp:*initial-processes*)
  (apply 'mp:process-run-function x))
```

This script saves a LispWorks image which starts multiprocessing on restart and runs a user-defined process.

```
(load-all-patches)
(load "my-server-code")
(push '("Start Server" () start-my-server)
      mp:*initial-processes*)
(save-image "my-server"
            :remarks "My Server"
            :restart-function 'mp:initialize-multiprocessing
            :environment nil)
```

See `save-image`, page 1001 for a description of how to save an image.

## 19.3 Atomicity and thread-safety of the LispWorks implementation

Access to all Common Lisp objects is thread-safe in the sense that it does not cause an error because of threading issues.

### 19.3.1 Immutable objects

Immutable (or read-only) objects such as numbers, characters, functions, pathnames and restarts can be freely shared between threads, but special precautions must be taken when all of the following conditions are true:

- A new object is made accessible to other threads ("globally accessible") by storing it in an object that is globally accessible.
- The store that makes it globally accessible is not by `(setf gethash)`, `vector-push` or `vector-push-extend` into a "multithreaded" hash-table or vector (see "Single-thread context arrays and hash-tables" on page 276).
- Other threads read from the globally accessible object without synchronizing with the thread that created it. Synchronizing is typically done by `lock`, but can also be done by using `barrier`, `condition-variable` or `semaphore`, and by using `hash-table` locks.

In this situation, it is your responsibility to ensure that all of the stores that occurred when creating the new object are visible to the other threads, as described by "Making an object's contents accessible to other threads" on page 268.

### 19.3.2 Mutable objects supporting atomic access

This section outlines for which types of mutable Common Lisp object access is atomic. That is, each value read from the object will correspond to the state at some point in time. Note however, that if several values are read, there is no guarantee about how these values will relate to each other if they are being modified by another thread (see “Issues with order of memory accesses” on page 276).

When one of these mutable atomic objects is modified, readers see either the old or new value (not something else), and it is guaranteed that the Lisp image is not corrupted by the modification even if multiple threads read or write the object simultaneously.

Access to conses, simple arrays except arrays with element type of integer with less than 8 bits, symbols, packages and structures is atomic. Note that this does not apply to non-simple arrays.

Slot access in objects of type `standard-object` is atomic with respect to modification of the slots and with respect to class redefinition.

`vector-pop`, `vector-push`, `vector-push-extend`, `(setf fill-pointer)` and `adjust-array` are all atomic with respect to each other, and with respect to other access to the array elements.

The Common Lisp functions that access hash tables are atomic with respect to each other. See also `modify-hash` for atomic reading and writing an entry and `with-hash-table-locked`. See also “Modifying a hash table with multiprocessing” on page 279 for thread-safe ways to ensure a table entry.

Access to packages is atomic.

Note that pathnames cannot be modified, and therefore access to them is always atomic.

Access to synchronization objects (of type `mailbox`, `barrier`, `semaphore` and `condition-variable`) is atomic. More information about these objects is in “Synchronization between threads” on page 285.

Operations on editor buffers (including points) are atomic and thread-safe as long as their arguments are valid. This includes modification to the text. However, buffers and points may become invalid because of execution on another thread. The macros `editor:with-buffer-locked` and `editor:with-point-`

`locked` should be used around editor operations on buffers and points that may be affected by other processes. Note that this is applicable also to operations that do not actually modify the text, because they can behave inconsistently if the buffer they are looking at changes during the operation. See the *LispWorks Editor User Guide* for details of these macros.

### 19.3.3 Mutable objects not supporting atomic access

This section outlines for which types of mutable Common Lisp object access is not atomic.

Access to arrays with element type of integer of less than 8 bits is not guaranteed to be atomic.

Access to non-simple arrays is not guaranteed to be atomic.

Access to lists (including alists and plists) is not atomic. Lists are made of multiple cons objects, so although access to the individual conses is atomic, the same does not hold for the list as a whole.

Sequence operations which modify multiple elements are not atomic.

Macros that expand to multiple accesses are in general not atomic. In particular, modifying macros like `push` and `incf` are not atomic (but see the atomic versions of some of them in “Low level atomic operations” on page 299).

Making several calls to Common Lisp functions that access hash tables will not be atomic overall. However LispWorks provides thread-safe ways to ensure a hash table entry - see “Modifying a hash table with multiprocessing” on page 279. See also `modify-hash` for atomic reading and writing an entry and `with-hash-table-locked`.

Stream operations are in general not atomic. There is an undocumented interface for locking of streams when this is required - contact Lisp Support if you need this.

Operations on CAPI objects are not atomic in general. The same is true for anything in the LispWorks IDE. These operations need to be invoked from the thread that owns the object, for example by `capi:execute-with-interface` or `capi:apply-in-pane-process`.

### 19.3.4 Making an object's contents accessible to other threads

An object's contents become accessible to other threads when it is stored into a cell that may be accessed by those threads (a "globally accessible cell"). In most cases, you should either use a synchronization mechanism (typically a `lock`) to control access to the cell because it is the most reliable approach or use a `mailbox` to make the object accessible to other threads (the mailbox acts as the globally accessible cell).

If you do not use a synchronization mechanism or mailbox, then all stores into the object must be forced to be visible to other threads ("ensured") before the object is stored in the globally accessible cell. This also applies to any stores that LispWorks did during construction of the object. Normally, LispWorks does not do that for every store, because it would slow the program too much. Note that numbers, except `fixnum` and `short-float` (in 32-bit LispWorks) or `fixnum` and `single-float` (in 64-bit LispWorks), are also objects that are constructed using stores that need to be ensured.

Storing objects into globally accessible cells would typically be done by `setf` or a related macro such as `push` or `incf`, but can also be done by Common Lisp functions such as `rplaca`, `fill`, `nsublis`, `nsubst` or `replace` (when the target is globally accessible). If stores into the objects that these functions store have not been ensured and may be read by another thread without synchronization, then one of the mechanisms in "Ways to guarantee the visibility of stores" on page 268 must be used. Note that when a sequence itself, rather than the elements, is modified, for example by `delete`, `nreverse`, `nconc`, `nunion`, then all access to the sequence needs to be controlled by a synchronization mechanisms, which will also guarantee the visibility of stores.

#### 19.3.4.1 Ways to guarantee the visibility of stores

The visibility (in other threads) of stores in an object referenced by a globally accessible cell can only be guaranteed in these situations:

1. You use a `lock` or any other synchronization mechanism (`barrier`, `condition-variable`, `semaphore`, `mailbox`, or the lock of a `hash-table`) to serialize all access to the globally accessible cell. Any use of a synchronization mechanism that may affect the behavior of another thread will implicitly ensure all preceding stores on the current thread.

2. The store is done by `(setf symbol-function)` or `(setf macro-function)` into a symbol, or by one of `(setf gethash)`, `vector-push`, `vector-push-extend` into a "multithreaded" hash-table or vector (see "Single-thread context arrays and hash-tables" on page 276).
3. You store a newly interned symbol (all stores that occur during interning are ensured). However, if the store is done using an operator that allocates (see "Special care for macros and accessors that may themselves allocate" on page 270) then you will still need to ensure.
4. You use one of the low level atomic operations, all of which ensure all stores on the current thread before they modify the cell. This includes stores from any allocation they may do and applies also to user defined atomic modify macros that are defined by `define-atomic-modify-macro`. Currently these atomic operations are: `compare-and-swap`, `atomic-exchange`, `atomic-push`, `atomic-pop`, `atomic-fixnum-incf`, `atomic-fixnum-decf`, `atomic-incf`, `atomic-decf`. Any atomic operations added in the future will do the same.
5. You start a new thread and access the object from that thread. LispWorks ensures all preceding stores on the current thread before the new thread runs, so if all accesses to an object occur in threads that start after the object was last modified then you do not need to ensure the stores into it.
6. You are storing an immediate object (`fixnum`, `character` or `short-float` in 32-bit LispWorks; `fixnum`, `character` or `single-float` in 64-bit LispWorks) in the globally accessible cell. There are no stores that need to be ensured during the creation of these objects. However, if the store is done using an operator that allocates (see "Special care for macros and accessors that may themselves allocate" on page 270) then you will still need to ensure.
7. The store is by `setf` or a related macro (for example `push` or `incf`), and the *place* argument is wrapped by the macro `globally-accessible`.
8. You call `ensure-stores-after-stores` between the time the object was made (and any stores of interest were done into it) and the time it is stored into a globally accessible cell. `ensure-stores-after-stores` ensures all preceding stores in the current thread.

Note: `ensure-memory-after-store` and `ensure-stores-after-memory` do what `ensure-stores-after-stores` does and more, but may be more expensive and are not required in this context.

Stores into objects must be "ensured" once by one of the above mechanisms, before the object becomes globally accessible. Stores that occur after this are not guaranteed to be visible to other threads until another ensuring operation.

In some circumstances you can make the program more efficient by explicitly ensuring stores using `globally-accessible` (7) or `ensure-stores-after-memory` (8) before or when the object is first made visible. See "Ensuring stores are visible to other threads" on page 271 for more details.

A synchronizing operation (1), atomic operation (4) or a call to `ensure-stores-after-stores` (8) ensures all stores into objects that were created by the current thread. The other situations ensure the stores that they perform and anything pointed to by those stores, but are not guaranteed to ensure other stores (because they may be able to skip ensuring in some circumstances).

#### **19.3.4.2 Special care for macros and accessors that may themselves allocate**

A situation that always requires special care is storing into a globally accessible cell using macros and accessors that may themselves allocate. If the store is not done using (1), (4) or (5) in "Ways to guarantee the visibility of stores" on page 268, then you need to use `globally-accessible` to ensure the stores in new objects that may be allocated are visible, even if the object that is stored does not need it (because it is an immediate, an interned symbol or was ensured earlier). These macros and accessors include:

Macros:            `push`, `pushnew`, `push-end`, `push-end-new`, `incf` (when not a fixnum), `decf` (when not a fixnum).

Accessors:        `getf`, `cdr-assoc`, `mask-field` (when not a fixnum), `ldb` (when not a fixnum).

User defined accessors that allocate:

Any user defined accessor (that is an operator with a `setf` expander defined by `define-setf-expander` or `defsetf`) that allocates during the setting operation. Note that allocation during the macro expansion is not an issue.

See “Destructive macros and accessors that allocate internally” on page 274 for more details.

### 19.3.5 Ensuring stores are visible to other threads

A store to a cell from one thread is said to be "visible" from another thread when a load from that cell from the other thread obtains the value that was stored. Within a single thread, all stores are visible immediately to loads from the same thread, but that is not always the case in a multithreaded situation. Store operations that occur in one thread are not necessarily visible from other threads until something ensures that they are. In other words, another thread loading from the cell where the store was done may still obtain the cell's previous value, even if "logically" it seems that the load happened after the store. For a new object, the previous value may be anything that was in memory, including an invalid value that may cause crashes.

#### 19.3.5.1 An example to consider the issues

For example, assume that the symbol `*a-global-symbol*` is not dynamically bound anywhere and its value is `nil`, and we have two threads, A and B, executing without synchronization.

Thread A executes this code:

```
(setq *a-global-symbol* (cons 1 2))
```

and thread B executes this code:

```
(let ((maybe-cons *a-global-symbol*))  
  (if (consp maybe-cons)  
      (car maybe-cons)  
      -1))
```

It looks like the form that thread B executes will always return either 1 (if it happens after thread A has set `*a-global-symbol*`) or -1 (otherwise), because in the case that `maybe-cons` is a cons it must already have 1 in the car. However, that is not necessarily true because the store of the cons into `*a-global-symbol*` may be visible to thread B before the store of 1 into the cons (which happens inside the call to `cons`) is visible. This applies to explicit stores in the program as well, for example if thread A executes:

```
(setq *a-global-symbol* (rplaca (list nil) 1))
```

then the same problem arises (in this case, the call to `car` in thread B may return 1, `nil` (the value that `list` stored in the car), or whatever was in that memory before that).

Note: the second load in thread B (inside `car`) is dependent on the first load (reading the value cell from `*a-global-symbol*`). Such dependent loads are guaranteed to occur in the program order in all current LispWorks releases. In situations when the two loads are independent, but you still need them to occur in the program order, you will need to use `ensure-loads-after-loads`.

### 19.3.5.2 The general solution using a lock

In most circumstances, all access to globally accessible cells should be controlled by a `lock`, which eliminates all of these problems because releasing a lock implicitly ensures that all stores in that thread are visible to all other threads, so by the time another thread gets ownership of the lock, all the stores are already visible. Sending an object via a `mailbox`, using `(setf gethash)`, `vector-push` or `vector-push-extend` or synchronizing using any of the other synchronization mechanisms (`barrier`, `condition-variable`, `semaphore` or the lock of a `hash-table`) also ensures the stores are already visible (for a full list, see “Making an object's contents accessible to other threads” on page 268). If you make an object globally accessible without any of these mechanisms, then you need to ensure explicitly that the stores are all visible. Note that if the store occurs inside a lock but the object is not read inside the same lock, then you still need to ensure the stores, because the reading may happen before unlocking has ensured the stores are visible. Note also that, for some macros and accessors (listed below), you need to ensure the stores even if the value that you store does not need ensuring.

### 19.3.5.3 An alternative solution using globally-accessible

If you need to explicitly ensure that all stores are visible, then the best approach is to use `globally-accessible`, which takes a single argument, `place`, which can be any generalized reference form as described in section [5.1.1 Overview of Places and Generalized Reference](#) of the Common Lisp HyperSpec. In most cases, (`globally-accessible place`) is the same as `place`. However, when `globally-accessible` is used inside `setf` or a related macro such as `push` or `incf` then it also ensures all stores are visible to other threads before modifying `place`. For example, if we change the code that thread A in Section 19.3.5.1 executes to:

```
(setf (sys:globally-accessible *a-global-symbol*)
      (cons 1 2))
```

then the value returned by the form in thread B is guaranteed to be 1 or -1 as expected.

### 19.3.5.4 An alternative solution using ensure-stores-after-stores

The other approach is to use `ensure-stores-after-stores` just before storing into the globally accessible cell, but after any allocation or other operations that modify the object being stored in the cell. In the example in Section 19.3.5.1, thread A would do:

```
(let ((cons (cons 1 2)))
  (sys:ensure-stores-after-stores)
  (setq *a-global-symbol* cons))
```

`ensure-stores-after-stores` cannot be used when the form that stores the object is a destructive macro such as `push` (for a full list, see “Destructive macros and accessors that allocate internally” on page 274 below), because `push` itself allocates a `cons` using stores that need to be ensured. `globally-accessible` takes care of that, by ensure the stores after any allocation that the macro may do (except when it is a macro with a non-standard `setf` expansion that allocates or stores in the setter). Thus `globally-accessible` is preferable when you can use it. You need to use `ensure-stores-after-stores` when the store is encapsulated in some other operation. For example, if you use `fill` to store a new object in a globally accessible sequence (`some-vector` below) then you will need to do something like this:

```
(let ((new-object (cons x y)))
  (sys:ensure-stores-after-stores)
  (fill some-vector new-object))
```

`ensure-stores-after-stores` always ensures all the stores that have happened in the current thread. `globally-accessible` is not guaranteed to ensure all preceding stores accept into the value that it stores, because it may be able to skip ensuring in some circumstances.

### 19.3.5.5 Destructive macros and accessors that allocate internally

The macros `push`, `pushnew`, `push-end`, `push-end-new`, `incf` (when not a fixnum) and `decf` (when not a fixnum) may generate new objects internally, so if they are used to destructively modify a globally accessible cell without synchronization then you will need to use `globally-accessible`.

For example:

```
(pushnew some-object (sys:globally-accessible *a-global-symbol*))
```

Note that `globally-accessible` is needed with `push`, `pushnew`, `push-end`, and `push-end-new` even if there are no stores into the object being pushed that need ensuring. For `incf` and `decf`, if you can guarantee that the new value is fixnum, then you do not need `globally-accessible`.

The accessors `getf`, `cdr-assoc`, `mask-field` and `ldb` take a *place* argument that may generate new objects when modified, so if *place* is globally accessible and it is modified without synchronization then you will need to wrap `globally-accessible` around such modifications of *place*.

For example:

```
(setf (getf (sys:globally-accessible *a-global-symbol*)
             :key)
      value)
```

For `getf` and `cdr-assoc`, `globally-accessible` is needed even if there are no stores into the new object and key that need ensuring because new conses might be added to the *place*. For `mask-field` and `ldb`, if you are absolutely sure that the new value is fixnum then you do not need `globally-accessible`.

In addition, `setf` expanders defined by `define-setf-expander` or `defsetf` cannot be used on globally accessible cells without synchronization (by a lock or other synchronization mechanism) if they do any of the following:

- allocate inside the value forms (the second value returned by `get-setf-expansion`);
- allocate inside the storing form (the fourth value returned by `get-setf-expansion`);
- store to anywhere except the *place*.

See section 5.1.1.2 *Setf Expansions* of the Common Lisp HyperSpec for the definition of "value forms" and "storing form".

#### 19.3.5.6 Miscellaneous notes

For an object that is not modified later, ensuring all stores when the object is created is sufficient, and after that the object can be used freely from any thread.

`ensure-stores-after-stores` can be used to ensure stores for objects that are modified after becoming globally accessible. However, if you need to ensure that the new values are seen by other threads that may be already accessing the modified objects then you need to use some synchronization mechanism anyway. Thus in most cases you should use a lock, which will deal with the synchronization.

`ensure-stores-after-stores` does slow the program a little on architectures that need it (Currently ARM, ARM64 and PowerPC), so you can consider the following optimizations:

- If you construct several objects that all need to be stored into globally accessible cells, then you can reduce the overhead by making them all, calling `ensure-stores-after-stores` once and then storing them all.
- If the store is done while holding a lock but the load is done without the lock, and loading happens less frequently than storing, then you may consider loading while holding the lock as well to avoid needing to explicitly ensure the stores.

As noted in “Ensuring stores are visible to other threads” on page 271, loads from an object that was obtained from a globally accessible cell are currently guaranteed to occur after the load the cell itself, because all the architectures that LispWorks runs on guarantee that. In principle, sometime in the future there may be a new architecture that does not provide that guarantee. You can guard against this by using `globally-accessible` when reading from the globally accessible cell as well. Currently that just macroexpands into its argument, so does not affect the performance, but for an architecture that requires anything it will do the right thing.

### 19.3.6 Issues with order of memory accesses

When multiple threads access the same memory location, the order of those accesses is not generally guaranteed. You should therefore not attempt to implement "lockless algorithms" which depend on the order of memory accesses unless you have a good understanding of multiprocessing issues at the CPU level (see “Ensuring order of memory between operations in different threads” on page 301).

However, all of the “Low level atomic operations” and locking operations (see “Locks” ) do ensure that all memory accesses that happen before them have finished and that all memory accesses that happen after them start after them. Therefore, normally there is nothing special to consider when using those operations. The modification check macros described in “Aids for implementing modification checks” also take care of this.

### 19.3.7 Single-thread context arrays and hash-tables

Access to hash tables and non-simple arrays can be improved where they are known to be accessed in a single thread context. That is, only one thread at the same time accesses them.

The `make-hash-table` argument *single-thread* tells `make-hash-table` that the table is going to be used only in single thread context, and therefore does not need to be thread-safe. Such a table allows faster access.

Similarly the `make-array` argument *single-thread* creates an array that is single threaded. Currently, the main effect of *single-thread* is on the speed of `vector-pop`, `vector-push`, and `vector-push-extend` on non-simple vectors. These

operations are much faster on "single threaded" vectors, typically more than twice as fast as "multithreaded" vectors.

You can also make an array be "single-threaded" with `set-array-single-thread-p`.

The result of parallel access to a "single-threaded" vector is unpredictable.

## 19.4 Locks

Locks can be used to control access to shared data by several processes.

The two main operators used in locking are the function `make-lock`, to create a `lock`, and the macro `with-lock`, to execute a body of code while holding the specified `lock`.

A `lock` has a name (a string) and several other components. The printed representation of a `lock` shows the name of the `lock` and whether it is currently locked. Additionally if the `lock` is locked it shows the name of the process holding the `lock`, and how many times that process has locked it. For example:

```
#<MP:LOCK "my-lock" Locked 2 times by "My Process" 2008CAD8>
```

The function `lock-owner` returns the process that locked a given `lock`.

The function `lock-name` returns the name of a `lock`.

The function `process-lock` blocks the current process until a given `lock` is claimed or a timeout passes, and `process-unlock` releases the `lock`.

The macro `with-lock` executes code with a `lock` held, and releases the `lock` on exit, as if by `process-lock` and `process-unlock`.

If you need to avoid blocking on a `lock` that is held by some other thread, then use `with-lock` with *timeout* 0, like this:

```
(unless (mp:with-lock (lock nil 0)
                      (code-to-run-if-locked)
                      t)
  (code-to-run-if-not-locked))
```

The macros `with-sharing-lock` and `with-exclusive-lock` can be used with sharing locks.

### 19.4.1 Recursive and sharing locks

The keyword argument *recursivep* to `make-lock`, when true, allows the `lock` to be locked recursively. *recursivep* is true by default. If *recursivep* is false then trying to `lock` again causes an error. This is useful for debugging code where the `lock` is not expected to be claimed recursively.

The keyword argument *sharing* to `make-lock`, when true, creates an "sharing" `lock` object, which supports sharing and exclusive locking. A sharing `lock` is handled by different functions and methods. See `with-exclusive-lock`, `with-sharing-lock`, `process-exclusive-lock`, `process-exclusive-unlock`, `process-sharing-lock` and `process-sharing-unlock`.

### 19.4.2 Querying locks

See `lock-recursive-p`, `lock-owned-by-current-process-p`, `lock-owner`, `lock-locked-p` and `lock-recursively-locked-p`.

### 19.4.3 Guarantees and limitations when locking and unlocking

In compiled code `process-lock`, `process-exclusive-lock` and `process-sharing-lock` are guaranteed to return if they locked their argument. In other words there will not be any throw between the time they locked the `lock` and the time they return. That means that in compiled code the next form will at least start executing, and if it is an `unwind-protect` the cleanup forms will at least start executing. (If the code is evaluated, this is not guaranteed.) "Locking" here also means incrementing the count of a `lock` that is already held by the current thread.

However these functions may throw before locking. For example, in the following code `process-lock` may throw without locking, for example because something interrupts the process by `process-interrupt`:

```
(unwind-protect
  (progn (mp:process-lock lock)
         (whatever))
  (mp:process-unlock lock))
```

If this call to `process-lock` does throw without locking, then `process-unlock` will be called on a `lock` that is not locked.

The correct code that guarantees (when compiled) that `process-unlock` is called on exit only when `process-lock` did lock is:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (mp:process-unlock lock))
```

Conversely, `process-unlock`, `process-exclusive-unlock` and `process-sharing-unlock` guarantee to successfully unlock the `lock`, but are not guaranteed to return.

For example, the following code may fail to call `another-cleanup`:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (mp:process-unlock lock)
  (another-cleanup))
```

If `another-cleanup` is essential to execute in all throws, it needs its own `unwind-protect`:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (unwind-protect
    (mp:process-unlock lock)
    (another-cleanup)))
```

**Note:** the guarantees described in this section are relevant only in compiled code.

## 19.5 Modifying a hash table with multiprocessing

Each `hash-table` access operation is thread-safe and atomic, but there is no guarantee of atomicity between access operations.

The modify macros (for example `incf`) all expand to two access operations, reading the value and writing the modified value, and are therefore not atomic. They need to be either done while holding a `lock`, or using `modify-hash`.

Another common operation is "ensuring an entry", that is reading and, if reading fails, adding a value to the table. For example:

```
(or (gethash key hash-table)
      (setf (gethash key hash-table) (construct-new-value)))
```

If two threads do that in parallel, one of them may end up with a value that is not in the table. One solution is to lock that table:

```
(with-hash-table-locked hash-table
  (or (gethash key hash-table)
      (setf (gethash key hash-table) (construct-new-value))))
```

However that always locks the table, which is inefficient. The correct way to do it is either to do:

```
(or (gethash key hash-table) ; first try without the lock
    (with-hash-table-locked hash-table
      (or (gethash key hash-table) ; check again inside the lock
          (setf (gethash key hash-table) (construct-new-value)))))
```

or use `gethash-ensuring` or `with-ensuring-gethash`.

## 19.6 Process Waiting and communication between processes

Process Waiting means that a process suspends its own execution until some condition is true. The generic Process Wait functions take a *wait-function* argument, which is arbitrary though somewhat restricted Lisp code. A process resumes running when the *wait-function* returns true. The specific Process Wait functions wait for a specific condition.

### 19.6.1 Specific Process Wait functions

For communication between processes, these are:

`mailbox-read`, `process-wait-for-event`, `mailbox-wait` and `mailbox-wait-for-event`.

For synchronization, these are:

`condition-variable-wait` and `barrier-wait`, also `semaphore-acquire` and `semaphore-release`.

For locking these are:

`process-lock`, `process-exclusive-lock` and `process-sharing-lock`.

For sleeping, these are:

`cl:sleep` and `current-process-pause`.

The specific Process Wait functions are designed to reduce latencies and to increase efficiency. In particular, in SMP LispWorks they should be used in preference to the generic Process Wait functions.

### 19.6.2 Generic Process Wait functions

The generic Process Wait functions are:

`process-wait` and `process-wait-with-timeout`

`process-wait-local` and `process-wait-local-with-timeout`

`process-wait-local-with-periodic-checks` and `process-wait-local-with-timeout-and-periodic-checks`.

**Note:** For brevity we sometimes refer to "the `*-periodic-checks` functions" or "the `*-with-timeout` functions".

All the generic Process Wait functions take *wait-reason* and *wait-function* arguments and potentially also arguments to pass to the *wait-function*. The `*-with-timeout` functions mentioned above also take a *timeout* argument. The `*-periodic-checks` functions also take a *period* argument.

The *wait-reason* is used only to mark the process as waiting for something for debugging purposes. It does not affect the behavior of the functions.

The generic Process Wait functions "wake up" (that is, they simply return to the caller) either when the timeout passed (if they take a *timeout* argument), or when the wait function returns true. The three pairs of functions mentioned above differ in the mechanism that calls the wait function.

`process-wait` and `process-wait-with-timeout` arrange that the "scheduler" will call the wait function when it runs. The "scheduler" is invoked at various points, in an indeterminate process. The advantage of this is that the programmer does not need to worry too much about when the wait function is going to be called. In non-SMP LispWorks (that is, LispWorks 5.1 and ear-

lier) the programmer does not need to worry at all: when some process sets up something that would make the wait function return true, the waiter process could not run anyway until the setting-up process stopped for some reason (including preemption), by which time the scheduler would have called the wait function if it had not done it before. In SMP LispWorks (that is, Lisp-Works 6.0 and later), these two processes can run simultaneously, so the delay between the setting up and the scheduling is not necessary. It can be avoided by "poking" the waiting process with `process-poke`, if the waiting process is known, or by invoking the scheduler by `process-allow-scheduling`.

**Note:** All the specific Process Wait functions, described in “Specific Process Wait functions” on page 280, record that they wait, and the operations that allow them to continue implicitly “poke” the waiting process. Therefore the specific functions avoid the problem of latency or needing `process-poke`, and should be used in preference where possible.

A large disadvantage of `process-wait` and `process-wait-with-timeout` is that their *wait-function* is called by the “scheduler” in an indeterminate process. That means that the wait function does not see the dynamic environment of the calling process (including error handlers), and cannot be debugged properly. It is also called often, and so it needs to be reasonably fast and not allocate much. In addition, having to call the wait function adds overhead to the system. Therefore in general, if you can achieve the required effect by using either any of the specific wait functions or a `process-wait-local*` function, you should do that and avoid `process-wait` and `process-wait-with-timeout`.

`process-wait-local` and `process-wait-local-with-timeout` do not have all the disadvantages listed above, but their *wait-function* is called only when the process is poked (or at the end of the *timeout*). That means that the programmer does not need to worry about when they are called. Typically some other process will set up something, and then poke the waiting process to check that it can run.

**Note:** if the setting up process always knows for sure whether the waiting process can run, then it is normally simpler to use one of the specific Process Wait functions, or maybe even `process-stop` and `process-unstop`.

The `*-periodic-checks` functions give a partial solution to the question of calling the wait function, by ensuring there is a maximum period of time between calls. If having a bounded delay where a bound of more than 0.1 sec-

ond is not a problem, then the `*-periodic-checks` functions are a simple and efficient way to achieve it.

When the delays need to be bounded by a shorter period, either one of the specific Process Wait functions or explicit calls to `process-poke` need to be used. The latter combined with `process-wait-local` is the most efficient mechanism, but it does require the programmer to ensure that `process-poke` is called in all the right places.

### 19.6.3 Communication between processes and synchronization

The simplest way to pass a specific event between two processes is to use `process-wait-for-event` on the receiving process, and `process-send` on the sender side. The "event" that is passed is can be any Lisp object.

`process-send` and `process-wait-for-event` use a `mailbox` to pass the object (the `process-mailbox` of the receiver). It is possible to use a `mailbox` object directly, and to communicate between multiple senders and receivers. Use `make-mailbox` to make a `mailbox`, and `mailbox-send` to put a message in it. In some situations there may be an imbalance between sending and receiving messages in a `mailbox`, which may cause the mailbox to become very big. When this is a problem, you can use `mailbox-send-limited` to make the sending process wait (or do something else) once the mailbox grows to some limit. There are also functions `mailbox-count`, `mailbox-size` and `mailbox-full-p` to help with these situations.

The receiver(s) use `mailbox-wait-for-event`, `mailbox-wait` OR `mailbox-read`. `mailbox-wait-for-event` should be used on processes that may make windows (including any process associated with a CAPI interface), but can be used elsewhere. `mailbox-read` is faster, but if it used on a process with a window it may cause hanging.

In general, the receiving process decides hows to interpret an event. However, the system has a "standard" generic function, `general-handle-event`, to interpret events. `general-handle-event` has methods that process lists by applying the `car` to the `cdr`, and processes function objects or symbols by calling them. There is a method on `t` that does nothing. You can add your own method on your defined classes (which can be structures).

`general-handle-event` is used when system code needs to interpret events, most importantly processes that CAPI uses to display windows use it. Hence for processes that use the "standard" event handling, you can send an object using `process-send` and expect it to be processed by `general-handle-event`. `general-handle-event` is also used by `process-all-events`, which processes all the events for the current process, and `wait-processing-events`, which waits until some predicate returns true while processing events.

In some situations it is useful to execute some code next time the current process processes events, rather than immediately. That can be achieved by `process-send` with the current process, or more conveniently by `current-process-send`.

`process-wait-for-event` and `process-send` and `mailbox` are the primary interface for communication between processes, and should be used unless there is a very good reason to use a different mechanism.

#### 19.6.4 Synchronization

Synchronization can be achieved by the various `process-wait*` functions with the appropriate `wait-function` argument, but for simple cases of synchronization it is better to use the synchronization objects: `condition-variable` or `barrier`. These synchronization objects are simple, efficient, deal with all thread-safety issues, and ensure that the processes that are ready to run will run immediately, rather than the next time that the wait function is called.

Condition variables (or type `condition-variable`) are used when one or more processes have the knowledge to control when another process(es) runs. The "ignorant" process(es) use `condition-variable-wait` to wait until they can continue. The "knowledgeable" process(es) use `condition-variable-signal` and `condition-variable-broadcast` to tell the "ignorant" processes when they can run. Because the communication is via the condition variable, the processes do not need to know explicitly about each other. For more details, see "Condition variables" on page 285.

Barriers (of type `barrier`) are used (mainly) for symmetric synchronization, when a group of processes needs to ensure that none of them goes too far ahead of the rest. The processes call `barrier-wait` when they want to synchronize, and `barrier-wait` waits until the other process arrive too (that is,

they call `barrier-wait`). Barriers have additional features that allow more complex synchronization. For more details, see “Synchronization barriers” on page 287.

## 19.7 Synchronization between threads

In LispWorks 5.1 and previous versions, the main way to synchronize between threads is to use `mp:process-wait` or `mp:process-wait-with-timeout` to supply a predicate to the scheduler. The predicate runs periodically in the background to identify threads that are no longer blocked.

These functions are still available, but there are some alternatives that can be more efficient in many cases by removing the need for the scheduler. The alternatives are:

- Mailboxes (FIFO queues). See `make-mailbox` and `mailbox-send`.
- Condition Variables (used with a `lock`). See “Condition variables” on page 285.
- Barriers (counting arrivals at a certain point in the code). See “Synchronization barriers” on page 287.
- Counting Semaphores (limiting the number of users of a shared resource). See “Counting semaphores” on page 287

Access to all of these objects is atomic and does not require additional locks (except for the `lock` that is already used with a `condition-variable`).

### 19.7.1 Condition variables

A `condition-variable` allows you to wait for some condition to be satisfied, based on the values stored in shared data that is protected by a `lock`. The condition is typically something like data becoming available in a queue.

The function `condition-variable-wait` is used to wait for a `condition-variable` to be signaled. It is always called with the `lock` held, which is automatically released while waiting and reclaimed before continuing. More than one thread can wait for a particular `condition-variable`, so after being notified about the condition changing, you should check the shared data to see if it represents a useful state and call `condition-variable-wait` again if not.

The function `condition-variable-signal` is used to wake exactly one thread that is waiting for the `condition-variable`. If no threads are waiting, then nothing happens.

Alternatively, the function `condition-variable-broadcast` can be used to wake all of the threads that are waiting at the time it is called.

Any threads that wait after the call to `condition-variable-signal` or `condition-variable-broadcast` will not be woken until the next call.

In most uses of condition variables, the call to `condition-variable-signal` or `condition-variable-broadcast` should be made while holding the `lock` that waiter used when calling `condition-variable-wait` for this `condition-variable`. This ensures that the signal is not lost if another thread is just about to call `condition-variable-wait`.

The function `condition-variable-wait-count` can be used to determine the current number of threads waiting for a `condition-variable`.

The `condition-variable` implementation in LispWorks aims to comply with the POSIX standard where possible.

`condition-variable-wait`, `condition-variable-signal` and `condition-variable-broadcast` have corresponding functions `lock-and-condition-variable-wait`, `lock-and-condition-variable-signal` and `lock-and-condition-variable-broadcast`. For `condition-variable-wait` there is also `simple-lock-and-condition-variable-wait`, which is simpler to use. The `lock-and-condition-...` functions perform the equivalent of locking and in the scope of the lock doing something and calling the corresponding `condition-...` function.

The `lock-and-condition-...` functions not only make it simpler to code, they also make it easier to avoid mistakes, and can optimize some cases (in particular, the quite common case when there is no need to lock on exit from `condition-variable-wait`). They are the recommended interface.

The `lock-and-condition-...` functions can be used together with `condition-...` functions on the same `locks` and `condition-variables`.

**Note:** In cases when only one process waits for the condition, using `process-wait-local` for waiting and `process-poke` for signaling is easier, and involves less overhead.

### 19.7.2 Synchronization barriers

Barriers are objects of type **barrier** that are used to synchronize multiple threads. A **barrier** has a *count* that determines how many "arrivals" (calls to **barrier-wait**) have to occur before these calls return.

The main usage of barriers is to ensure that a group of threads have all finished some stage of an algorithm before any of them proceeds.

The typical way of using a **barrier** is to make one with a *count* that is the same as the number of threads that are going to work in parallel and then create the threads to do the work. When each thread has done its work, it synchronizes with the others by calling **barrier-wait**. In most cases **barrier-wait** is the only barrier API that is used.

For example, assume you have a task that be broken into two stages, where each stage can be done in parallel by several threads, but the first stage must be completely finished before any processing of the second stage can start. Then the code will do:

```
(let ((barrier (mp:make-barrier num-of-processes)))
  (dotimes (p num-of-processes)
    (mp:process-run-function (format nil "Task worker ~d" p)
      ()
      #'(lambda (process-number barrier)
          (do-first-stage process-number)
          (mp:barrier-wait barrier)
          (do-second-stage process-number))
      p
      barrier)))
```

It is also possible to use a **barrier** to block an indefinite number (up to **most-positive-fixnum**) of processes, until another process decides that they can go. For this the **barrier** is made with *count t* (or **most-positive-fixnum**). The other process then uses **barrier-disable** to "open" the **barrier**. If required, the **barrier** can be enabled again by **barrier-enable**.

See also **barrier-block-and-wait**.

### 19.7.3 Counting semaphores

A counting semaphore is a synchronization object that allows different threads to coordinate their use of a shared resource that contains some num-

ber of available units. The meaning of each unit depends on what the semaphore is being used to synchronize.

The three main functions associated with semaphores are: `make-semaphore`, which makes a new `semaphore` object; `semaphore-acquire`, which acquires units from a `semaphore` and `semaphore-release`, which releases units back to a `semaphore`. The current thread will block if it attempts to acquire more units than are current available.

The functions `semaphore-name`, `semaphore-count` and `semaphore-wait-count` can be used to query the name, available unit count and count of waiting units from a `semaphore`.

## 19.8 Killing a process, interrupts and blocking interrupts

### 19.8.1 Killing a process

When the function of the process (third argument to `process-run-function`) returns the process exits, but in many cases it is more convenient to terminate the process without returning all the way to the process function.

The function `current-process-kill` can be used to kill the current process. It executes all the unwind forms on the stack first. Checking in appropriate places and calling `current-process-kill` is a convenient and safe way (as long as there are `unwind-protect` forms where needed) of causing processes to exit when they should.

`process-terminate` can be used to kill any process. If there is no Terminate Method (see `current-process-set-terminate-method`) it uses the process interrupting mechanism, so if the other process blocks interrupts it will continue to run until it stops blocking. Because the killing interrupt can happen inside unwind forms of `unwind-protect` (unless they are executed with interrupts blocked) `process-terminate` is not safe unless all essential unwinding forms are executed with interrupts blocked. In most cases it is probably easier to not use `process-terminate` in actual applications.

## 19.8.2 Interrupting a process

`process-interrupt` and `process-interrupt-list` can be used to interrupt a process and execute arbitrary code. Since the interrupt happens at a "random" time, it should have minimal interaction with any data structures that are being modified. For robust applications it is probably better never to use it except during development.

## 19.8.3 Blocking interrupts

The purpose of blocking interrupts is to prevent a process aborting in the middle of an operation that needs to be completed. A typical example is the cleanup forms of an `unwind-protect`.

Blocking interrupts does not provide atomicity. Other processes may continue to execute.

Blocking interrupts limits the control that LispWorks has over the processes, so interrupts should not be blocked except when necessary. However, apart from blocking interrupts in a process it does not affect the behavior of the system.

The following macros and functions allow control over blocking interrupts: `allowing-block-interrupts`, `with-interrupts-blocked`, `current-process-unblock-interrupts` and `current-process-block-interrupts`.

Additionally the macros `unwind-protect-blocking-interrupts` and `unwind-protect-blocking-interrupts-in-cleanups` allow your program to prevent interrupts from stopping cleanup forms from completing.

**Compatibility note:** In LispWorks 5.1 and previous versions, `mp:without-preemption` and `mp:without-interrupts` are sometimes used to block interrupts, but they also provide atomicity. In many cases (probably most), they are used to provide atomicity, and in these cases they cannot be replaced by blocking interrupts. To get atomicity in LispWorks 6.0 and later you need to use locks or atomic operations. To get atomicity while debugging, you can also use `with-other-threads-disabled`.

#### 19.8.4 Old interrupt blocking APIs removed

The macros `mp:without-interrupts` and `mp:without-preemption`, which were available in LispWorks 5.1 and earlier, are no longer supported. The semantics of these macros allowed them to be used for several different purposes, which now require specific solutions.

- Atomic operations. This use was designed to make operations atomic with respect to other uses of the same macro or with respect to some other unquantified operations that were expected to be atomic, such as reading or writing a single slot in an object. Code of this kind should be converted to use locks (see “Locks” on page 277) or low level atomic operations (see “Low level atomic operations” on page 299).
- Complete operations. This use was designed to ensure that a set of operations completed without being interrupted by `mp:process-interrupt`, keyboard breaks and so on. See “Blocking interrupts” on page 289 for the new approach.

The following subsections show examples of typical uses of the old interrupt blocking APIs together with their replacements. The examples use `mp:without-interrupts` but the ideas also apply to uses of `mp:without-preemption`.

##### 19.8.4.1 Atomic increment

Old:

```
(without-interrupts
  (incf *global-counter*))
```

New: use low level atomic operations.

```
(sys:atomic-incf *global-counter*)
```

##### 19.8.4.2 Atomic push/pop

Old:

```
(without-interrupts
  (push value *global-list*)
  (without-interrupts
    (pop *global-list*)))
```

New: use low level atomic operations.

```
(sys:atomic-push value *global-list*)
(sys:atomic-pop *global-list*)
```

### 19.8.4.3 Atomic push/delete

Old:

```
(without-interrupts
  (push value *global-list*))
  (without-interrupts
    (setq *global-list* (delete value *global-list*)))
```

New: use a **lock**, because delete cannot be done atomically since it reads more than one object before modifying one of them.

```
(defvar *global-list-lock* (mp:make-lock :name "Global List"))

(mp:with-lock (*global-list-lock*)
  (push value *global-list*))

(mp:with-lock (*global-list-lock*)
  (setq *global-list* (delete value *global-list*)))
```

### 19.8.4.4 Atomic plist update

Old:

```
(without-interrupts
  (setf (getf *global-plist* key) value))
  (without-interrupts
    (getf *global-plist* key))
```

New: use a **lock**, because a plist consists of more than one object so cannot be updated with low level atomic operations.

```
(defvar *global-plist-lock* (mp:make-lock :name "Global Plist"))

(mp:with-lock (*global-plist-lock*)
  (setf (getf *global-plist* key) value))

(mp:with-lock (*global-plist-lock*)
  (getf *global-plist* key))
```

#### 19.8.4.5 Atomic update of a data structure

The example below is a resource object, which maintains a count of free items and also list of them. These two slots must stay synchronized.

Old:

```
(without-interrupts
  (when (plusp (resource-free-item-count resource))
    (decf (resource-free-item-count resource))
    (pop (resource-free-items resource))))
```

New: use a lock, because more than one slot has to be updated, so cannot be updated with low level atomic operations.

```
(mp:with-lock ((resource-lock resource))
  (when (plusp (resource-free-item-count resource))
    (decf (resource-free-item-count resource))
    (pop (resource-free-items resource))))
```

#### 19.8.4.6 Atomic access to a cache in a hash table

Old:

```
(without-interrupts
  (or (gethash value *global-hashtable*)
      (setf (gethash value *global-hashtable*)
            (make-cached-value))))
```

New: use the hash table lock.

```
(hcl:with-hash-table-locked
  *global-hashtable*
  (or (gethash value *global-hashtable*)
      (setf (gethash value *global-hashtable*)
            (make-cached-value))))
```

Alternative new: use the hash table lock only if the value is not already cached. This can be faster than the code above, because it avoids locking the hash table for concurrent reads.

```
(or (gethash value *global-hashtable*); probe without the lock
    (hcl:with-hash-table-locked
      *global-hashtable*
      (or (gethash value *global-hashtable*); reread with the lock
          (setf (gethash value *global-hashtable*)
                (make-cached-value)))))
```

## 19.9 Timers

Use timers to run code after a specified time has passed. You can schedule a timer to run once or repeat at regular intervals, and you can unschedule it before it expires.

The timers are measured in elapsed time and the accuracy depends on various factors, including the operating system and the load on the computer.

For the details, see the reference entries for `make-timer` and `schedule-timer`.

### 19.9.1 Timers and multiprocessing

Timers run in unpredictable threads, therefore it is not safe to run code that interacts with the user directly. The recommended solution is something like

```
(mp:schedule-timer-relative
  (mp:make-timer 'capi:execute-with-interface
    interface
    'capi:display-message "Time's up")
  5)
```

or

```
(mp:schedule-timer
  (mp:make-timer 'capi:execute-with-interface
    interface
    'capi:display-message "Lunchtime")
  (* 4 60 60))
```

where *interface* is an existing CAPI interface on the screen.

Timers actually run in the process that is current when the scheduled time is reached. This is likely to be The Idle Process in cases where LispWorks is sleeping, but it is inherently unpredictable.

### 19.9.2 Input and output for timer functions

I/O streams default to the standard input and output of the process, which is initially `*terminal-io*` in the case of The Idle Process.

## 19.10 Process properties

A "process property" is a pair of an indicator and a value that is associated with it for a process.

LispWorks has two kinds of process properties: general and private. These two kinds of properties are stored separately, and the association of indicator/value in each property kind is independent of any in the other property kind.

General properties are stored in the process plist, and can be modified from other processes.

Private properties can only be modified by the current process. Private properties are faster to modify, because the modification does not need to be thread-safe.

Otherwise there is little difference between general and private properties.

`process-plist` and `(setf process-plist)` are not thread-safe. In LispWorks 5.1 and earlier the only interface to process properties is `process-plist`, but this does not work well in SMP LispWorks, and so it is deprecated.

There is no parallel to `process-plist` for the private properties.

The general properties are accessed by: `process-property`, `(setf process-property)`, `remove-process-property`, `pushnew-to-process-property` and `remove-from-process-property`.

The private properties are accessed by: `get-process-private-property` (access from other processes), `process-private-property`, `(setf process-private-property)`, `remove-process-private-property`, `pushnew-to-process-private-property` and `remove-from-process-private-property`.

## 19.11 Other processes functions

### 19.11.1 Process Priorities

Each process has a priority and can either be runnable, blocked or suspended.

The effect of process priorities is significantly different between SMP LispWorks and non-SMP LispWorks.

### 19.11.1.1 Process priorities in SMP LispWorks

Process priorities are almost completely ignored in SMP LispWorks.

The main exception is that for processes that wait with `process-wait` for something to happen, a process with higher priority is likely to wake up earlier, but even then it is not guaranteed.

### 19.11.1.2 Process priorities in non-SMP LispWorks

If there is a runnable process with priority P, then no processes with priority less than P will run. When there are runnable processes with equal priority, they will be scheduled in a round-robin manner.

If a process with priority P is running and a blocked process with priority greater than P becomes runnable, the second process will run when the scheduler is next invoked (either explicitly or at the next preemption tick).

To find the priority of a process, use `process-priority`. This can be changed using `change-process-priority`.

```
(mp:change-process-priority proc-1 10)
```

Another way to specify the priority is to create the process with `process-run-function`, passing the keyword `:priority`:

```
(list
  (mp:process-run-function
    "SORTER-DOT" '(:priority 10) #'sorter #\.)
  (mp:process-run-function
    "SORTER-DASH" () #'sorter #\-))
```

### 19.11.2 Accessing symbol values across processes

Use `symeval-in-process` to read the value of a dynamically bound symbol in a given process.

`(setf mp:symeval-in-process)` can set the value of such a symbol.

`symeval-in-process` is mostly intended for debugging. Do not call it while the thread is actually running.

### 19.11.3 Stopping and unstopping processes

This section describes a typical way of using `process-stop` and `process-unstop`.

Suppose a pool of "worker" processes is managed by a "manager" process. A process in the worker pool marks itself as available for work, and then calls `process-stop`. The manager process later finds a worker process that is marked as available for work, puts the work in a place known to the worker process, and then calls `process-unstop` on the worker process.

For this scheme to work properly, the check of whether the worker is available needs to include a call to `process-stopped-p`. Otherwise, it is possible for the following sequence of events to occur:

1. A worker marks itself as available.
2. The manager process finds the worker and gives it the work.
3. The manager process calls `process-unstop` on the worker.
4. The worker process proceeds and calls `process-stop`, and never wakes up.

To guard against this possibility, then the manager should call `process-stopped-p` when finding the worker in the second step above. Alternatively, it could check the result of `process-unstop`.

## 19.12 Native threads and foreign code

Support for native threads differs between platforms as described in this section.

### 19.12.1 Native threads on Windows, Mac OS X, Linux, x86/x64 Solaris, FreeBSD and AIX

Each Lisp `mp:process` has a separate native thread and in LispWorks 6.0 and later versions these threads can run simultaneously.

**Note:** In LispWorks 5.1 and earlier versions, you can have many runnable `mp:process` objects/native threads, but Lisp code can only run in one thread at a time and a lock is used to enforce this. This can limit performance on a

computer with multiple CPU cores. When a foreign function is called using the FLI, the lock is released until the function returns. This allows other Lisp threads to run, for instance while waiting for a database query to execute.

You can call back into Lisp using `fli:define-foreign-callable` in any thread, without any other setup.

Threads running Lisp code can be rescheduled preemptively, so if you call into Lisp from more than one thread simultaneously and one request takes a long time then it will not delay the requests in other threads.

### 19.12.2 Native threads on other platforms

Lisp uses a single native thread and implements user level threads to support `mp:process`.

You can only call back into Lisp from its single native thread.

**Note:** This section applies only to LispWorks for SPARC Solaris.

### 19.12.3 Foreign callbacks on threads not created by Lisp

When foreign code creates a native thread (a "foreign thread") and code running on this thread calls into Lisp, then Lisp needs to associate a Lisp process object with this thread to be able to work properly.

When there is a call on a foreign thread into Lisp which is not a recursive call (an "outer call"), Lisp first checks if there is a process associated with this thread, and if there is it uses it. Otherwise, it creates a new process and associates it with the foreign thread. Recursive calls into Lisp (when Lisp calls foreign code which calls back into Lisp) are processed in the same way as recursive calls in Lisp threads.

When the outer call returns, Lisp by default keeps the process associated with the thread, but this is not guaranteed. Keeping the process means that next call into Lisp requires less work, but comes at the cost of using more memory. Lisp eliminates the process if it detects that the thread has died, if there is call to `last-callback-on-thread` inside the outer call or if the process is killed by `process-terminate`.

Once Lisp has a process associated with the thread, it establishes it as the current process, as returned by calling `get-current-process`, and then calls the foreign callable Lisp code.

Part of establishing the process involves binding the variables in `*process-initial-bindings*`. Note that this binding happens repeatedly for each outer call. The computation of the bound value is done when the process is created, so if the process is not eliminated between outer calls (the default behavior), this happens only once. The computation of the value occurs in the dynamic environment of the new process.

Compatibility note: Before LispWorks 7.1, the computation occurred in a "no-process" scope, and an error would have entered the debugger in the console without an option to abort.

#### 19.12.3.1 Performance considerations for foreign threads

Keeping the process between outer calls (the default behavior), makes each call faster, but uses memory. For few processes, this is probably the best approach. With many processes, the memory usage may become an issue.

There is an overhead for an outer call, which is larger than a recursive call. A few outer calls per second should not be a problem, but it should be avoided inside a heavy computation.

## 19.13 Low level operations

### 19.13.1 Low level atomic operations

Low level atomic operations are defined in all cases for a specific set of places. These places are listed in Table 19.1:

Table 19.1 Places for low-level atomic operations

Place	Notes
<code>(symbol-value symbol)</code>	When <i>symbol</i> is dynamically bound, this means the dynamically bound value.
A dynamically bound <i>symbol</i>	The dynamically bound value.
A lexically bound <i>symbol</i>	It is an error to use a low level atomic operation on a lexically bound symbol.
<code>(car cons)</code>	
<code>(cdr cons)</code>	
<code>(the type place)</code>	For another <i>place</i> listed in this table.
<code>(svref sv index)</code>	Only <code>simple-vector</code> .
Structure accessors	The structure must be defined at compile time.
<code>(slot-value object slot-name)</code>	See below.

Notes about atomic `slot-value` operations:

1. They ignore the MOP `slot-value-using-class` protocol and can only be used for `:instance` and `:class` allocated slots.

2. They are slower than the atomic operations on other types of object because they have to lock the instance. Normally it would be better to have a slot pointing to some other object (for example a structure) and do the atomic operations on that object.

The low level atomic operations implicitly ensure order of memory between operations in different threads.

The low level atomic operations are: `atomic-push`, `atomic-pop`, `atomic-fixnum-incf`, `atomic-fixnum-decf`, `atomic-incf`, `atomic-decf`, `atomic-exchange` and `compare-and-swap`.

Application of macros that are defined by `define-atomic-modify-macro` is also restricted to the places in Table 19.1 above, because they implicitly use low level atomic operations.

You can test whether a place is suitable for use with these operations by the predicate `low-level-atomic-place-p`.

### 19.13.2 Aids for implementing modification checks

The macros `with-modification-check-macro` and `with-modification-change` provide a way for a body of code to execute and check whether there was any "modification" during this execution, where modification is execution of some other piece of code. This is useful in situations when reading some data out of some data structure is more common than modification, and reading the data involves getting some values that need to be consistent. It makes it possible to ensure consistency of the values without a `lock`.

The checking code should be wrapped by the macro `with-modification-check-macro`, and the modifying code should be wrapped by the macro `with-modification-change`. They are associated by the fact that their `modification-place` argument is the same.

`modification-place` is a place as defined in Common Lisp (it does not need to be one of the places for atomic locking) which can receive a fixnum. It must be initialized to a fixnum. It must not be modified by any code except `with-modification-change`.

`with-modification-check-macro` defines a lexical macro (by `macrolet`) with the name `macro-name` which takes no arguments, and is used to check whether there was any change since the entering the body.

Note that these macros do not guard against errors that may occur because of changes to the data structures that are accessed, and do not create any locking between users of these macro. In particular, the modifying code will typically need to lock something too, and the checking code must do only operations that cannot fail because of modification in another thread.

### 19.13.2.1 Example modification check

```
(defstruct my-cache
  (modification-count 0)
  a
  b)

;; modifier code
(sys:with-modification-change
 (my-cache-modification-count cache)
 (setf (my-cache-a cache) (calculate-a-value ....)
       (my-cache-b cache) (calculate-b-value ....)))

;; reading code
(loop
 (sys:with-modification-check-macro
  my-cache-did-not-change-p (my-cache-modification-count cache)
  (let ((a (my-cache-a cache))
        (b (my-cache-b cache)))
    (when (my-cache-did-not-change-p)
      (return (values a b)))))
```

Provided that all modification to the `a` and `b` slots of a `my-cache` object are done by the modifier code above, the return values of `a` and `b` in the reading code are guaranteed to have been set by the same `setf` invocation in the modifier code.

### 19.13.3 Ensuring order of memory between operations in different threads

A set of synchronization functions is provided which ensure order of memory between operations in different threads. These are `ensure-loads-after-`

`loads`, `ensure-memory-after-store`, `ensure-stores-after-memory` and `ensure-stores-after-stores`.

**Note:** You should have a good understanding of multiprocessing issues at the CPU level to write code that actually needs these functions.

The effect of each of these functions is to ensure that all the operations of the first type (the word following the `ensure-`) that are in the program after the call to the function are executed after all the operations of the second type (last word in the function name) that are in the program before the call to the function.

Before or after "in the program" means the order that a programmer interpreting (correctly) the program would expect the operations to be executed. On a modern CPU this is not necessarily the same as the actual execution order. On a single CPU the end result is guaranteed to be the same, but on a computer with multiple CPU cores it is not.

An operation of type *load* is an operation that reads data from an object into a local variable. Typical *load* operations are `car`, `cdr`, `svref`, structure accessors, `slot-value` and getting the value of a symbol. A *store* operation is an operation that modifies data in an object. A *memory* operation is either a *load* or a *store*.

You need these functions when you need to synchronize between threads and you do not want to use the system supplied synchronization objects ("Locks", mailboxes, "Condition variables", "Counting semaphores", "Synchronization barriers"). In most cases you should try first to use a synchronization object. Using the synchronization functions described in this section is useful if you can identify a serious bottleneck in your code that can be optimized using them.

For simple cases you should consider whether `with-modification-check-macro` and `with-modification-change` gives you the functionality you need.

### 19.13.3.1 Example of ensuring order of memory

Suppose you have two code fragments, which may end up executed in parallel, and both of which access a global structure `*gs*`. The first fragment is a

setter, and you can be sure that it is not executed in parallel to itself (normally because it actually runs while holding a `lock`):

```
(setf
  (my-structure-value-slot *gs*) ; store1
  some-value)
(setf
  (my-structure-counter-slot *gs*) ; store2
  counter)
```

The second fragment is the reader. You want to guarantee that it gets a value that was stored after the counter reached some value (the counter value always increases). You may think that this will suffice:

```
(if (>=
      (my-structure-counter-slot *gs*) ; load1
      counter)
    (my-structure-value-slot *gs*) ; load2
  (.. something else ...))
```

Programmatically, if the `>=` is true then `store2` already occurred before `load1`, therefore `store1` also occurred before `load1`, and `load2` which happens after `load1` must happen after `store1`.

On a single CPU that is true. On a computer with multiple CPU cores it can go wrong (that is, `load2` can happen before `store1`) because of two possible reasons:

1. `load2` may happen before `load1`.
2. `store2` may happen before `store1`.

To guarantee that `load2` happens after `store1`, both of these possibilities need to be dealt with. Thus the setter has to be:

```
(setf (my-structure-value-slot *gs*) ; store1
      some-value)
(sys:ensure-stores-after-stores) ; ensure store order
(setf (my-structure-counter-slot *gs*) ; store2
      (incf-counter))
```

and the reader has to be:

```
(if (> (my-structure-counter-slot *gs*) ; load1
      my-counter)
    (progn
      (sys:ensure-loads-after-loads) ; ensure load order
      (my-structure-value-slot *gs*)) ; load2
    (.. something else ...))
```

Note that somehow both threads know about `counter`, and normally will have to synchronize the getting of its value too.

# 20

---

# Common Defsystem and ASDF

This chapter describes tools for managing programs comprising many source files. Most of the material concerns LispWorks' native `defsystem` ("Common Defsystem"), but the last section describes how to use the popular open source alternative ASDF with LispWorks.

## 20.1 Introduction

When an application becomes large, it is usually prudent to divide its source into separate files. This makes the individual parts of the program easier to find and speeds up editing and compiling. When you make a small change to one file, just recompiling that file may be all that is necessary to bring the whole program up to date.

The drawback of this approach is that it is difficult to keep track of many separate files of source code. If you want to load the whole program from scratch, you need to load several files, which is tedious to do manually, as well as prone to error. Similarly, if you wish to recompile the whole program, you must check every file in the program to see if the source file is out of date with respect to the object file, and if so re-compile it.

To make matters more complicated, files often have interdependencies; files containing macros must be loaded before files that use them are compiled. Similarly, compilation of one file may necessitate the compilation of another

file even if its object file is not out of date. Furthermore, one application may consist of files of more than one source code language, for example Lisp files and C files. This means that different compilation and loading mechanisms are required.

The LispWorks system tools, and the System Browser in the LispWorks IDE, are designed to take care of these problems, allowing consistent development and maintenance of large programs spread over many files. A system is basically a collection of files that together constitute a program (or a part of a program), plus rules expressing any interdependencies which exist between these files.

You can define a system in your source code using the `defsystem` macro. Once defined, operations such as loading, compiling and printing can be performed on the system as a whole. The system tools ensure that these operations are carried out completely and consistently, without doing unnecessary work. A system may itself have other systems as members, allowing a program to consist of a hierarchy of systems. Each system is treated independently of the others, and can be used to collect related pieces of code within the overall program. Operations on higher-level systems are invoked recursively on member systems.

It is also possible to define a system in your code using `asdf:defsystem`, an open source system definition utility with similar functionality to LispWorks `defsystem`. See “Using ASDF” on page 311 for a description of how to use ASDF with LispWorks.

## 20.2 Defining a system

A system is defined with a `defsystem` form in an ordinary Lisp source file. This form must be loaded into the Lisp image in order to define the system in the environment. Once loaded, operations can be carried out on the system by invoking Lisp functions, or, more conveniently, by using the system browser.

For example, the expression:

```
CL-USER 5 > (compile-system 'debug-app :force t)
```

would compile every file in a system called `debug-app`.

**Note:** When defining a hierarchy of systems, the leaf systems must be defined first — that is, a system must be declared before any systems that include it.

By convention, system definitions are placed in a file called `defsys.lisp` which usually resides in the same directory as the members of the system.

The full syntax is given in `defsystem`, page 1109. Below is a brief introduction.

### 20.2.1 DEFSYSTEM syntax

`defsystem` takes four arguments: *name*, *options*, *members* and *rules*.

*name* should be a string that names the system.

*options* is a list of keyword-value pairs specifying attributes of the system such as the default location of its member files or the default compiler optimize qualities in effect when `compile-system` is called.

*members* lists the members of the system which can be source files (of Common Lisp or foreign code) or other systems (that is, subsystems).

*rules* is a set of rules describing the requirements for compilation and loading of the system members and the order in which this should take place.

See the following sections for more information about these parameters.

### 20.2.2 DEFSYSTEM options

Options may be specified to `defsystem` which affect the behavior of the system as a whole. For example, `:package` specifies a default package into which files in the system are compiled and loaded if the file itself does not contain its own package declaration. The `:default-pathname` option tells the system tools where to find files which are not expressed as a full pathname.

### 20.2.3 DEFSYSTEM members

The `:members` keyword to `defsystem` is used to specify the members of a system. The argument given to `:members` is a list of strings. A system member is either a file or another system, identified by a name. If a full pathname is given then the function `pathname-name` is used to identify the name of the

member. Thus, for example, the name of a member expressed as `/u/duby/a/foo.lisp` is `foo`.

System members must have unique names, by a case-insensitive string comparison, so if a system has a member called "`foo`" then it cannot have another member (a file or a system) named "`foo`", "`FOO`" or `foo`.

The behavior of any member within a system can be constrained by supplying keyword arguments to the member itself. So, for example, specifying the `:source-only` keyword ensures that only the source file for that member is ever loaded.

#### 20.2.4 DEFSYSTEM rules

Rules may be defined in a system which modify the default behavior of that system, ensuring, for instance, that certain files are always loaded or compiled before others.

Rules apply to files and subsystems alike as members of their parent system, but are not inherited by subsystems.

When you invoke an action such as compiling a system, the following happens by default:

- Each member of the system is considered in turn, in the order they are given in the system definition.
- If the member is itself a system then the action is performed on that system too, and so on recursively.
- If the member is a file and action-specific constraints are satisfied, the file action is inserted into a *plan*.

For example, in the case of compiling, a “compile this file” event is put into the plan if the source file is newer than the object file.

- After the plan has been assembled, it can be viewed or executed.

This behavior can be modified by describing dependencies between the members using *rules*. These are specified using the `:rules` keyword to `defsystem`.

A rule has three components:

The target(s).	The action that is performed if the rule executes successfully.
	This is an action-member description like <code>:compile "foo"</code> . The member can be an actual member of the system or <code>:all</code> (meaning the rule should apply to each member of the system).

The actions that the target(s) are `:caused-by`.

The actions that cause the rule to execute successfully.

This is a list of action-member descriptions. The member of each of these descriptions should be either a real system member, or `:previous`, which means all members listed before the member of the target in the system description.

If any of these descriptions are already in the current plan (as a result of other rules executing successfully, or as a result of default system behavior), they trigger successful execution of this rule.

The actions that the target(s) `:requires`.

The actions that need to be performed before the rule can execute successfully.

This is a list of action-member descriptions that should be planned for before the action on the target(s). Again, each member should either be a real member of the system, or `:previous`.

The use of the keyword `:previous` means, for example, that you can specify that in order to compile a file in the system, all the members that come before it must be loaded.

When the action and member of a target are matched during the traversal of the list of members, the target is inserted into the plan if either of the following are true:

- any of the action-member descriptions in the `:caused-by` clause is already in the plan, or

- any implicit conditions (such as the source file being newer than the object file) are satisfied.

If the target is put into the plan then other targets are inserted beforehand if the action-member description of any `:requires` clause is not already in the plan.

### 20.2.5 Examples

Consider an example system, `demo`, defined as follows:

```
(defsystem demo (:package "USER")
  :members ("parent"
            "child1"
            "child2")
  :rules ((:in-order-to :compile ("child1" "child2"))
           (:caused-by (:compile "parent")))
           (:requires (:load "parent"))))
```

This system compiles and loads members into the `USER` package if the members themselves do not specify packages. The system contains three members — `parent`, `child1`, and `child2` — which may themselves be either files or other systems. There is only one explicit rule in the example. If `parent` needs to be compiled (for instance, if it has been changed), then this causes `child1` and `child2` to be compiled as well, irrespective of whether they have themselves changed. In order for them to be compiled, `parent` must first be loaded.

Implicitly, it is always the case that if any member changes, it needs to be compiled when you compile the system. The explicit rule above means that if the changed member happens to be `parent`, then every member gets compiled. If the changed member is not `parent`, then `parent` must at least be loaded before compiling takes place.

The next example shows a system consisting of three files:

```
(defsystem my-system
  (:default-pathname "~/junk/")
  :members ("a" "b" "c")
  :rules ((:in-order-to :compile ("c"))
           (:requires (:load "a")))
           (:caused-by (:compile "b"))))
```

What plan is produced when all three files have already been compiled, but the file `b.lisp` has since been changed?

First, file `a.lisp` is considered. This file has already been compiled, so no instructions are added to the plan.

Second, file `b.lisp` is considered. Since this file has changed, the instruction `compile b` is added to the plan.

Finally file `c.lisp` is considered. Although this has already been compiled, the clause

```
(:caused-by (:compile "b"))
```

causes the instruction `compile c` to be added to the plan. The compilation of `c.lisp` also requires that `a.lisp` is loaded, so the instruction `load a` is added to the plan first. This gives us the following plan:

1. Compile `b.lisp`.
2. Load `a.lisp`.
3. Compile `c.lisp`.

This last example shows how to make each fasl get loaded immediately after compiling it:

```
(defsystem my-system ()
  :members ("foo" "bar" "baz" "quux")
  :rules ((:in-order-to :compile :all
    (:requires (:load :previous)))))

(compile-system my-system :load t)
```

## 20.3 Using ASDF

You can load the supplied version of ASDF 2 by

```
(require "asdf")
```

Optionally, if you actually want your later version of ASDF 2, do

```
(asdf:load-system :asdf)
```

You may need to configure ASDF. For the language-level interface you should follow the ASDF documentation at <http://common-lisp.net/project/asdf/>.

Then load your ASDF system definitions and you are ready to work with ASDF systems in LispWorks.

It is possible to work with both Common Defsystem and ASDF in the same LispWorks image, as long as you use the appropriate APIs to operate on each type of system.

### 20.3.1 Bypassing the supplied version of ASDF

To use a specific version of ASDF 2 without loading the version supplied with LispWorks, you should load it directly and then call

```
(provide "asdf")
```

to prevent the distributed version from being loaded later.

### 20.3.2 Using ASDF in the LispWorks IDE

You can work with your ASDF systems using the LispWorks IDE tools.

This needs some integration code which makes the System Browser, Editor and Search Files tools work with ASDF systems as well as 'native' LispWorks systems. The ASDF integration code is in

```
(example-edit-file "misc/asdf-integration")
```

in the LispWorks library and if necessary you can load it directly. However, it is more convenient to rely on this code being loaded automatically.

The variable `*autoload-asdf-integration*` is consulted when the LispWorks IDE starts. If its value is true (this is the default) then the ASDF integration code is loaded automatically when ASDF is loaded.

See the comments in `asdf-integration.lisp` for more information about using ASDF with LispWorks.

## The Parser Generator

### 21.1 Introduction

The parser generator generates an LALR parser from a specification of a grammar. The parser generator has a simple facility for the static resolution of ambiguity in the grammar and supports an automatic run time error correction mechanism as well as user-defined error correction. Semantic actions can be included in the rules for the grammar by specifying Lisp forms to be evaluated when reductions are performed.

For further details on LALR parsing, see *Compilers, Principles Techniques and Tools*, by Aho, Sethi and Ullman, publishers Addison Wesley, 1986.

Load the parser generator by (`(require "parsergen")`).

### 21.2 Grammar rules

The parser generator is accessed by the macro `defparser`. After the *name*, of the parser, the macro form specifies the reduction rules and semantic actions for the grammar.

The *rules* specified in a `defparser` form are of three types, *normal rules*, *error rules* and *combined-rules*, described below.

Each *normal rule* corresponds to one production of the grammar to be parsed:

```
( (non-terminal {grammar-symbol}*) {form}*)
```

The *non-terminal* is the left-hand side of the grammar production and the list of grammar symbols defines the right-hand side of the production. (The right-hand side may be empty.) The list of forms specifies the semantic action to be taken when the reduction is made by the parser. These forms may contain references to the variables \$1 ... \$n, where n is the length of the right hand side of the production. When the reduction is done, these variables are bound to the semantic values corresponding to the grammar symbols of the rule.

### 21.2.1 Example

If a grammar contains the production:

```
expression -> expression operator expression
```

with a semantic representation of a list of the individual semantic values, the Lisp grammar would contain the rule:

```
((expression expression operator expression) (list $1 $2 $3))
```

Error productions of the form:

```
((nt :error) (some error behavior))
```

are explained in the section below.

The first rule of the grammar should be of the form:

```
((nt nt1) $1)
```

where the non-terminal *nt* has no other productions and *nt1* serves as the main “top-level” non-terminal.

### 21.2.2 Combined rules

The *combined-rule* clause is a way to group multiple *normal-rule* or *error-rule* clauses for the same non-terminal. For example, this single *combined-rule* clause:

```
(constant
  ((:FLOAT-CONSTANT) $1)
  ((:INTEGER-CONSTANT) $1))
```

is equivalent to these two *normal-rule* clauses:

```
((constant :FLOAT-CONSTANT) $1)
((constant :INTEGER-CONSTANT) $1)
```

### 21.2.3 Resolving ambiguities

If the grammar is ambiguous, there is conflict between rules of the grammar: either between reducing with two different rules or between reducing by a rule and shifting an input symbol. Such a conflict is resolved at parser generation time by selecting the highest priority action, where the priority of a reduce action is determined by the closeness of the rule to the beginning of the grammar. A priority is assigned to a shift by associating it with the rule that results in the shift being performed.

For example, if the grammar contains the two rules:

- Rule a: *statement* -> `:if expression :then statement :else statement`
- Rule b: *statement* -> `:if expression :then statement`

this results in a conflict in the parser between a shift of `:else`, for rule a, and a reduce by rule b. This conflict may be resolved by listing rule a earlier in the grammar than rule b. This ensures that the shift is always done.

Note that ambiguities cannot always be resolved successfully in this way. In this example, if the ambiguity is resolved the other way around, by listing rule b first, this results in the `if ... then ...` part of an `if ... then ... else ...` statement being reduced, and a syntax error is produced for the `else` part.

During parser generation, any conflicts between rules are reported, together with information about how the conflict was resolved.

## 21.3 Functions defined by defparser

The form `(defparser name grammar)` defines a number of functions. The main function *name* is defined as the parsing function. For example:

```
(defparser my-parser .. grammar .. )
```

defines the function

```
my-parser lexer &optional symbol-to-string =>
```

`lexer` specifies the lexical analyzer function to be used. The optional argument `symbol-to-string` should be a function mapping grammar symbols to strings for printing purposes. The default value of `symbol-to-string` is the function `c1:identity`.

`defparser` also defines functions corresponding to the individual actions of the parser.

Normal actions are named:

`name-actionindex`

and error actions are named:

`name-error-actionindex`

where `name` here is the name as given to `defparser` and `index` is the number of the rule or error rule in the grammar.

All function names are interned in the current package when `defparser` is called.

## 21.4 Error handling

The parser supports automatic error correction of its input. The strategy used involves attempting to either push a new token onto the input, replacing an erroneous symbol, or discarding an erroneous symbol. Such action is only taken if it is guaranteed that the parser can continue parsing and read at least one more symbol from its input.

If the correction strategy fails, then error recovery is invoked.

The parser allows the inclusion of grammar productions of the form:

`non-terminal -> :error`

This means that the parser accepts an erroneous string of tokens as constituting an occurrence of the non-terminal. Such productions may be used to skip over portions of input when attempting to recover from an error. The action associated with such an error is specified by a form in the same way as for ordinary actions. The action may perform manipulation of the parser state and input.

## 21.5 Interface to lexical analyzer

The lexical analyzer function that is passed to the parser is expected to be a function of zero arguments that returns two values each time it is called. The first value is the next token on the input and the second value is the semantic value corresponding to that token. If there is no more input, then the lexical analyzer may return either the token `:eof` or `nil`.

For example:

```
(defparser my-parser
  ...)

(defun my-lexer (stream)
  .. read next token from stream ..
  (values token value))
(defun my-symbol-to-string (symbol)
  .. returns a string ..)
(defun my-parse-stream (stream)
  (let ((lexer #'(lambda () (my-lexer stream))))
    (my-parser lexer #'my-symbol-to-string)))
```

Note that during error correction, the parser may push extra tokens onto the input, in which case they are given the semantic value `nil`. The semantic actions should therefore be capable of dealing with this situation. Manipulation of the input (for example pushing extra tokens) is done within the parser generator and the lexical analyzer need not concern itself with this.

## 21.6 Example

The following example shows a simple grammar for a very small subset of English.

```

(defpackage "ENGLISH-PARSER")
  (:use "PARSERGEN")
  (:add-use-defaults t))
(in-package "ENGLISH-PARSER")

;; Define the parser itself.

(defparser english-parser
  ((bs s) $1)
  ((s np vp)
   `($1 ,$2))
  ((bnp :adj bnp)
   `($1 ,$2))
  ((bnp bnp relp)
   `($1 ,$2))
  ((bnp :noun) $1)
  ((relp :rel vp)
   `($1 ,$2))
  ((vp :verb np locp)
   `($1 ,$2 ,$3))
  ((vp :verb locp)
   `($1 ,$2))
  ((vp :verb np)
   `($1 ,$2))
  ((vp :verb)
   $1)
  ((np :art bnp locp)
   `($1 ,$2 ,$3))
  ((np :art bnp)
   `($1 ,$2))
  ((np bnp) $1)
  ((locp :loc np)
   `($1 ,$2)))

;; The lexer function.

;; The basic lexing function

(defvar *input*)
(defun lex-english ()
  (let ((symbol (pop *input*)))
    (if symbol (get-lex-class symbol)
        nil)))

;; Getting syntactic categories.

(defparameter *words*

```

```
'((the :art) (a :art) (some :art) (ate :verb) (hit :verb)
(cat :noun) (rat :noun) (mat :noun) (which :rel) (that :rel)
(who :rel) (man :noun) (big :adj) (small :adj) (brown :adj)
(dog :noun) (on :loc) (with :loc) (behind :loc) (door :noun)
(sat :verb) (floor :noun)))

(defun get-lex-class (word)
  (values
    (or (cadr (assoc word *words*))
        :unknown)
    word))

;;; The main function -- note bindings of globals (these
;;; are exported from the parsergen package).

(defun parse-english (input)
  (let ((*input* input)
        (english-parser #'lex-english)))
```

The following example session shows the parsing of some sentences.

```
ENGLISH-PARSER 34 > (parse-english '(the cat sat on the
                                      mat))
((THE CAT) (SAT (ON (THE MAT)))))

ENGLISH-PARSER 35 > (parse-english '(the big brown dog
                                      behind the door ate the cat
                                      which sat on the floor))
((THE (BIG (BROWN DOG)) (BEHIND (THE DOOR)))
 (ATE (THE (CAT (WHICH (SAT (ON (THE FLOOR))))))))
```

# 22

# Dynamic Data Exchange

## 22.1 Introduction

Dynamic data exchange (DDE) involves passing data and instructions between applications running under the Microsoft Windows operating system. Typically the data is passed in the form of a string, which is interpreted when it is received. One application acts as a *server* and the other as a *client*.

### 22.1.1 Types of transaction

The server is normally a passive object, which waits for a client object to tell it what to do. The client can communicate with the server in four ways:

- The client can issue a *request transaction* to the server. This means the client is asking for some information about the server application.
- The client can issue a *poke transaction*. This means the client is passing data to be stored by the server application.
- The client can issue an *execute transaction*. This means the client is asking the server to get the server application to run a command.
- The client can ask the service to set up an *advise loop*, or to close an existing advise loop. An advise loop causes the server to communicate with the client whenever a specified change occurs in the server application.

### 22.1.2 Conversations, servers, topics, and items

For a transaction to take place between a client and a server, a conversation must be established. A conversation is established when a client makes a request by broadcasting a service name and topic name, and a server responds. Transactions can then take place across the conversation. When no more transactions are to be made, the conversation is terminated.

The following list identifies the elements involved with client/server activity:

- |              |   |
|--------------|---|
| conversation | A conversation is established when a server responds to a client.   |
| service name | A service name is a string broadcast by a client hoping to establish a conversation with a server that recognizes the service name. The service name is usually clearly related to the server application name.   |
| topic name   | The topic name identifies what the conversation between client and server is to be about. For example, it could be the name of a file that is open in the server application. Each topic is attached to one particular server. A server can have many topics. |
| item name    | The item usually identifies an element of the file identified by the topic which should be read (in the case of a request) or written to (in the case of a poke). For example, it might refer to a cell in a spreadsheet document.                            |

### 22.1.3 Advise loops

A DDE advise loop describes a connection back to the application that is used to track changes to a DDE topic. It instructs the server to inform the client when data in the server's application changes. Advise loops are set up across a conversation, and closing the conversation closes the advise loop.

An advise loop is identified by an item and a key. The key is included to allow any number of uniquely identifiable advise loops to be set up on the same server/topic/item combination.

A successfully established advise loop is also known as a link. When a change occurs to item, the link informs the client by causing it to execute a function.

There are two types of link: the warm link which only informs the client that a change to item has occurred, and the hot link which also sends the new data across.

**Note:** a DDE advise loop is not a loop in the program source code. In particular it should not be confused with the "event loop" which is a loop in source code that processes low level events.

#### 22.1.4 Execute transactions

When a client issues an execute transaction to a server, the command to be executed is transferred as a string. This involves the marshalling of the command and its arguments into a suitable string format. The standard format of such a string is:

```
[command(arg1,arg2,...)]
```

## 22.2 Client interface

### 22.2.1 Opening and closing conversations

A LispWorks client can open a conversation by using `dde-connect`, which takes a service designator and a topic designator as its arguments. If successful, a conversation object is returned which can be used to refer to the conversation. Conversations are closed by the LispWorks client at the end of a transaction by using `dde-disconnect`.

Another method for managing conversations uses `with-dde-conversation` to bind a conversation with a server across a body of code. If no conversation is available for `with-dde-conversation`, then one is automatically opened. The code is executed and the conversation is closed after the body of code exits.

### 22.2.2 Automatically managed conversations

There is an alternative to manually establishing a conversation and then disconnecting it once all transactions between server and client are concluded: the automatically managed conversation. Client functions that end with a \* conduct automatically managed conversations.

A function handling an automatically managed conversation takes a service designator and topic designator as two of its arguments, and either automatically establishes a conversation with a server responding to the service designator/topic designator pair, or uses an existing equivalent conversation. For the purpose of brevity, functions conducting automatically managed conversations are only briefly mentioned in this chapter. For the details see `dde-advise-start*`, `dde-advise-stop*`, `dde-execute*`, `dde-execute-command*`, `dde-execute-string*`, `dde-item*`, `dde-poke*` and `dde-request*`.

### 22.2.3 Advise loops

A LispWorks client can set up an advise loop across a conversation using `dde-advise-start`, which takes a *conversation* (or a *service designator/topic* designator pair in the case of an automatically managed conversation using `dde-advise-start*`), an *item*, and a *key* as its main arguments. The *key* argument defaults to the conversation name, and can be used to distinguish between multiple advise loops established on the same service/topic/item group.

Whenever the data monitored by the advise loop changes, a function is called to inform the client. By default this function is the generic function `dde-client-advise-data`. You can add methods to `dde-client-advise-data` specialized on the *key* or the client conversation class. Alternatively, you can supply a different function in the call to `dde-advise-start`.

**Note:** a DDE advise loop is not a loop in the program source code. In particular it should not be confused with the "event loop" which is a loop in source code that processes low level events.

#### 22.2.3.1 Example advise loop

The example shows you how to set up an advise loop. The code assumes that `win32` package symbols are visible.

The first step defines a client conversation class, called `my-conv`.

```
(defclass my-conv (dde-client-conversation)
  ())
```

The macro `define-dde-client` can now be used to define a specific instance of the `my-conv` class for referring to a server application that responds to the service name "FOO".

```
(define-dde-client :foo :service "FOO" :class my-conv)
```

The next step defines a method on `dde-client-advise-data` which returns a string stating that the item has changed.

```
(defmethod dde-client-advise-data ((self my-conv) item data &key
  &allow-other-keys)
  (format t "~&Item ~s changed to ~s~%" item data))
```

Finally, the next command starts the advise loop on the server `foo`, with the topic name "`file1`", to monitor the item "`slot1`".

```
(dde-advise-start* :foo "file1" "slot1")
```

When the value of the item specified by "`slot1`" changes, the server calls `dde-client-advise-data` which returns a string, as described above.

The *function* argument of `dde-advise-start` and `dde-advise-start*` specifies the function called by the advise loop when it notices a change to the item it is monitoring. The function is `dde-client-advise-data` by default. A different function can be provided, and should have a lambda list similar to the following:

```
key item data &key conversation &allow-other-keys
```

The arguments *key* and *item* identify the advise loop, or link. The argument *data* contains the new data for hot links; for warm links it is `nil`.

Advise loops are closed using `dde-advise-stop` or `dde-advise-stop*`.

#### 22.2.4 Request and poke transactions

LispWorks clients can issue request and poke transactions across a conversation using `dde-request` and `dde-poke`, which take a *conversation* (or a *service designator/topic* designator pair in the case of an automatically managed conversation), and an *item* as their main arguments. In the case of a poke transaction, data to be poked into *item* must also be provided.

In the case of a successful request transaction with `dde-request` or `dde-request*`, the data contained in *item* is returned to the LispWorks client by the server.

In the case of a successful poke transaction with `dde-poke` or `dde-poke*`, the data provided is poked into *item* by the server.

The accessor `dde-item` (or `dde-item*` for automatically managed conversations) can perform request and poke transactions. It performs a request transaction when read, and a poke transaction when set.

### 22.2.5 Execute transactions

A client can issue an execute transaction across a conversation, or in the case of an automatically established conversation, to a recognized server. There is no need to specify a topic, as an execute transaction instructs the server application to execute a command.

The command and its arguments are issued to the server in the form of a string in a standard format (see “Execute transactions” on page 323). LispWorks provides two ways of issuing an execute transaction, namely `dde-execute-string` and `dde-execute-command` (and the corresponding \* functions that automatically manage conversations).

The following example shows how `dde-execute-string*` can issue a command to a server designated by `:excel` on the topic `:system`, in order to open a file called `foo.xls`:

```
(dde-execute-string* :excel :system "[open(\"foo.xls\")]")
```

The function `dde-execute-command` takes the command to issue, and its arguments, and marshals these into an appropriate string for you. The following example shows how `dde-execute-command*` can issue the same command as in the previous example:

```
(dde-execute-command* :excel :system 'open '("foo.xls"))
```

## 22.3 Server interface

### 22.3.1 Starting a DDE server

To provide a LispWorks application with a DDE server, follow the following three steps.

1. Define a specialized Lisp DDE server class using `define-dde-server`. Here the server class is called `foo-server` and it has the service name "FOO":  

```
(define-dde-server foo-server "FOO")
```
2. Provide the server class with the functionality it requires by specializing methods on it and/or using `define-dde-server-function`. Here the server function is `bar`, which takes a string as an argument, and prints this to the standard output. For convenience, the system topic is used, though usually it is better to define your own topic.  

```
(define-dde-server-function (bar :topic :system)
    :execute
    ((x string))
    (format t "~&~s~%" x)
    t)
```

3. Start an instance of the server `foo-server` using `start-dde-server`.

```
(start-dde-server 'foo-server)
```

This function returns the server object, which responds to requests for conversations with the service name "FOO", and accepts execute transactions for the function `bar` in the "System" topic.

### 22.3.2 Handling poke and request transactions

Poke and request transactions issued to a server object are handled by defining a method on each of the generic functions `dde-server-poke` and `dde-server-request`.

### 22.3.3 Topics

DDE servers respond to connection requests containing a service name and a topic name. The service name of a server is the same for any conversation

whereas the topic name may vary from conversation to conversation, and identifies the context of the conversation. Typically, valid topics correspond to open documents within the application, so the set of valid topics varies from time to time. In addition, all servers implement a topic called "`System`", which contains a standard set of items that can be read.

The LispWorks DDE interface supports three types of topics:

- 1. General topics**

A general topic is an instance of a user-defined topic class. The actual set of topics available may vary from time to time as the application is running.

- 2. Dispatching topics**

A dispatching topic has a fixed name, and is available at all times that the server is running. It supports a fixed set of items, and each of these items has Lisp code associated with it to implement these items.

- 3. The system topic.**

The system topic is provided automatically by the LispWorks DDE interface. However, a mechanism is provided to extend the functionality of the system topic by handling additional items.

### 22.3.3.1 General topics

To use general topics, the LispWorks application must define one or more subclasses of `dde-topic`. If an application supports only a single type of document, it will typically require only one topic class. If several different types of document are supported, it may be convenient to define a different topic class for each type of document.

If the application uses general topics, it should define a method on the `dde-server-topics` generic function, specializing on the application's server class.

### 22.3.3.2 Dispatching topics

A dispatching topic is a topic which has a fixed name and always exists. Dispatching topics provide dispatching capabilities, whereby appropriate appli-

cation-supplied code is executed for each supported transaction. Dispatch topics are defined using `define-dde-dispatch-topic`.

### 22.3.3.3 The system topic

The system topic is implemented as a predefined dispatching topic called `:system`. It is automatically available to all defined DDE servers. Its class is `dde-system-topic`, which is a subclass of `dde-topic`.

The following items are implemented by the system topic:

<b>SZDDESYS_ITEM_TOPICS</b>	<i>Constant</i>
-----------------------------	-----------------

The constant `SZDDESYS_ITEM_TOPICS` has the value "`Topics`". Referring to this item in the system topic calls `dde-server-topics` to obtain a list of topics implemented by the server. The server should define a method on this generic function to return a list of strings naming the topics supported by the server. If this item is not to be implemented, do not define a method on the function, or define a method that returns `:unknown`.

<b>SZDDESYS_ITEM_SYSITEMS</b>	<i>Constant</i>
-------------------------------	-----------------

The constant `SZDDESYS_ITEM_SYSITEMS` has the value "`sysItems`". Referring to this item in the system topic calls `dde-topic-items` to obtain a list of items implemented by the system topic. If a server implements additional system topic items it should define a method on the generic function specialized on its server class and `dde-system-topic` returning the complete list of supported topics. The server can return `:unknown` if this item is not to be implemented.

<b>SZDDESYS_ITEM_FORMATS</b>	<i>Constant</i>
------------------------------	-----------------

The constant `SZDDESYS_ITEM_FORMATS` has the value "`Formats`", and returns `unicodetext` and `text`. Currently only text formats are supported.

The system topic is a single object which is used by all DDE servers running in the Lisp image. You should therefore not under normal circumstances modify

it with `define-dde-server-function` by specifying a value of `:system` for the *topic* argument, as this would make the changes to the system topic visible to all users of DDE within the Lisp image.

Instead, specify `:server my-server :topic :system`, where *my-server* is the name of your DDE server. This makes the additional items available only on the system topic of the specified server.

# Common SQL

This chapter is applicable to UNIX LispWorks and the Enterprise Edition of LispWorks. It describes Common SQL — the LispWorks interface to SQL. It should be used in conjunction with Chapter 47, “The SQL Package”, which contains full reference entries for all the symbols in the SQL package.

For a longer introduction to Common SQL, please see the SQL Tutorial available at [www.lispworks.com](http://www.lispworks.com).

## 23.1 Introduction

This chapter covers the following areas:

- Initialization and Connection
- The Functional SQL Interface
- The Object-Oriented (CLOS) SQL Interface
- The Symbolic SQL Syntax
- SQL I/O Recording
- SQL Interface Errors

The LispWorks SQL interface uses the following database terminology:

***Data Definition Language (DDL)***

The language used to specify and interrogate the structure of the database schema.

***Data Manipulation Language (DML)***

The language used for retrieving and modifying data.  
Also known as *query language*.

<i>table</i>	A set of records. Also known as <i>relation</i> .
<i>attribute</i>	A field of information in the table. Also known as <i>column</i> .
<i>record</i>	A complete set of attribute values in the table. Also known as <i>tuple</i> , or <i>row</i> .
<i>view</i>	A display of a table configured to your own needs. Also known as <i>virtual table</i> .

### 23.1.1 Overview

Common SQL is designed to provide both embedded and transparent access to relational databases from the LispWorks environment. That is, SQL/relational data can be directly manipulated from within Lisp, and also used as necessary when instantiating or accessing particular Lisp objects.

The SQL interface allows the following:

- Direct use of standard SQL statements as strings
- Mixed symbolic SQL and Common Lisp expressions
- Implicit SQL invocation when instantiating or accessing CLOS objects

The SQL interface provides these features through two complementary layers:

- A *functional* SQL interface
- An *object-oriented* SQL interface

The functional interface provides users with Lisp functions which map onto standard SQL DML and DDL commands. Special iteration constructs which utilize these functions are also provided. The object-oriented interface allows users to manipulate database views as CLOS classes via `def-view-class`.

### 23.1 Introduction

The two interfaces may be flexibly combined in accordance with system requirements and user preference. For example, a *select* query can be used to initialize slots in a CLOS instance; conversely, accessing a CLOS slot may trigger an implicit functional query.

#### 23.1.2 Supported databases

Common SQL supports connections to various databases using the driver/client libraries for each interface-platform combination as indicated below in Table 23.1.

Common SQL may work, but is currently untested, with driver/interface/platform combinations shown as "None tested". We would be pleased to hear of your experience with these other driver/interface/platform combinations, at [lisp-support@lispworks.com](mailto:lisp-support@lispworks.com):

Table 23.1 Supported driver/client libraries for each interface-platform combination

interface (module name)	"odbc"	"oracle"	"postgresql"	"mysql"	"sqlite"
Default database type	<code>:odbc-driver</code>	<code>:oracle</code>	<code>:postgresql</code>	<code>:mysql</code>	<code>:sqlite</code>
Other database type	<code>:odbc</code>	<code>:oracle8</code>	None	None	None
Windows	Microsoft SQL Server Oracle Postgres	Oracle 9i(r2) and later	Postgres	MySQL	SQLite 3.6.12 or later
Mac OS X	MySQL Postgres	Oracle 10g and later	Postgres	MySQL	SQLite 3.6.12 or later
Linux	MySQL Postgres	Oracle 9i(r2) and later	Postgres	MySQL	SQLite 3.6.12 or later
FreeBSD	None tested	Not supported	Postgres	MySQL	SQLite 3.6.12 or later
Solaris/Intel	None tested	Oracle 10g and later	Postgres	MySQL	None tested

Table 23.1 Supported driver/client libraries for each interface-platform combination

<i>interface</i> (module name)	"odbc"	"oracle"	"postgresql"	"mysql"	"sqlite"
AIX	None tested	Oracle 11 and later	None tested	None tested	None tested
Solaris/SPARC	None tested	Oracle 9i(r2) and later	None tested	MySQL	None tested

The keyword shown in the second and third rows is the corresponding value of the *database-type* argument to `connect`. When a client library version is shown, it is the earliest version that was tested successfully: later versions should work too, and in many cases earlier versions may work too.

**Note:** MySQL versions prior to 4.1.1 should be run in ANSI mode to work with Common SQL. That is, `mysqld` must be started with `--ansi` or the `ansi` option must appear in the `[mysqld]` section of its configuration file.

**Note:** To use PostgreSQL on any non-Microsoft Windows platform, LispWorks/Common SQL requires PostgreSQL version  $\geq 8.x$  built with `--enable-thread-safety`.

## 23.2 Initialization

The initialization of Common SQL involves three stages. Firstly the SQL interface is loaded. Next, the database type (actually class) to be used is initialized. Finally, Common SQL is used to connect to a database. These stages are explained in more detail in this section.

The Lisp symbols introduced in this chapter are exported from the `sql` package. Application packages requiring convenient access to these facilities should therefore use the `sql` package.

The examples in this chapter assume that the `sql` package is visible.

### 23.2.1 Initialization steps

Three steps are required to initialize the SQL interface:

1. At load time, the SQL interface is loaded.

## 23.2 Initialization

2. At run time, database type(s) are initialized. This step can be merged into step 3.
3. A connection is made to a database server. All further operations use the connection.

The remainder of this section describes how you perform these steps.

1. Load the SQL interface by calling `require` with the name of a database interface.

Currently implemented interfaces are "oracle", "mysql", "odbc", "postgresql" and "sqlite". However, not all platforms support all interfaces, see Table 23.1, page 333 for details.

The same application can use more than one interface, and needs to call `require` to load each interface that it uses.

Loading is done at load time. In particular, if you are building an application, loading needs to be done before calling `deliver`.

2. Initialize the database type, either when connecting or by an explicit call.

Every connection has a database type, which defines the functionality to use when performing operations on it. Each interface defines one or more database types that can be used as the database type. The database type must be initialized, which can be done either when connecting, or by explicitly calling `initialize-database-type`. Initializing a database type must be done at run time, in other words you should not save an image (by `save-image` or `deliver`) with an initialized database type.

Initializing a database type typically means that the system finds the library that implements the client, loads and initializes it. (Actually, there may be several libraries.) It is possible to delay the initialization until making the connection, but it is useful to do the initialization explicitly first as this allows you to catch errors in the initialization and report them.

The variable `*default-database-type*` holds the value of the default type, which is used when a database type is not supplied. The first database interface that is loaded sets `*default-database-type*` to its default database type. Therefore in a typical setup using one interface you do not need to specify the database type.

The database types currently supported are shown in Table 23.2:

Table 23.2 Supported database types

Interface	<i>database-type</i>	Comments
"oracle"	:oracle	default
"oracle"	:oracle8	for backwards compatibility
"mysql"	:mysql	default
"postgresql"	:postgresql	default
"odbc"	:odbc-driver	default
"odbc"	:odbc	uses <code>SQLConnect</code> rather than <code>SQLDriverConnect</code>
"sqlite"	:sqlite	default

### 3. Connect to a database by calling `connect`.

The main argument to `connect` is a connection-spec, which is interpreted in a database type specific way. See the entry for `connect` for details. By default, `connect` uses the database type in `*default-database-type*`, but it can be specified explicitly by the keyword argument `:database-type`. If the database type was not initialized yet, `connect` initializes it.

The result of `connect` is an object which is referred to as "database object", but it is really a connection object representing a connection to the server. It is possible to have multiple database objects connected independently to the same database server.

The database object is used by all the other Common SQL interface functions. `connect` sets the value of `*default-database*` to the result each time it is called, so a call to a SQL interface function without specifying the database always acts on the last connected database. That allows simpler code when there is only one connection. When there is more than one connection, you need to pass the database object to the interface function via the keyword argument `:database`.

## 23.2 Initialization

When a connection is no longer required, it should be closed by calling `disconnect`.

The minimal code to initialize a connection is loading the code and connecting. For example, using only Oracle:

```
(require "oracle")
(sql:connect "scott/tiger")
```

However, if you deliver an application then the `require` call needs to happen at load time (before calling `deliver`), while the `connect` call must happen at run time after the delivered application started. So your code should have two parts:

- In the script that loads the application code:

```
(require "oracle")
```

- In the code itself, at various places:

```
(sql:connect "scott/tiger")
```

To get better error handling, you may want to add a call to `initialize-database-type`, in the startup function:

```
(handler-case
  (sql:initialize-database-type)
  (error (cc)
    ;; tell the user of failure to initialize Oracle
  ))
```

### 23.2.2 Database libraries

**Note:** This section applies only to Unix-like operating systems.

To use a database, LispWorks needs to load foreign libraries, which is done when initializing the database type. To find the right libraries and initialize them, there may be vendor-specific environment variable(s) that need to be set, for example `ORACLE_HOME` for Oracle. Typically one of these will point to a directory where the database code is installed. You may need to ensure that these variables are set properly when your application is used.

In order to override the default loading of database library code, you may set `*sql-libraries*`. To control messages while loading the libraries, set `*sql-loading-verbose*`.

### 23.2.3 General database connection and disconnection

Database connections can be named by passing the `:name` argument to `connect`, allowing you to have more than one connection to a given database. If this is omitted, then a unique database name is constructed from `connection-spec` and a counter. Connection names are compared with `equalp`.

To find all the database connection instances, call the function `connected-databases`. To retrieve the `name` for a connection instance, call `database-name`, and to find a connection instance with a given name use `find-database`. To print status information about the existing connections, call `status`.

To close a connection to a database, use `disconnect`.

To reestablish a connection to a database, use `reconnect`.

#### 23.2.3.1 Connection example

The following example assumes that the `:odbc` database type has been initialized as described in “Initialization steps” on page 334. It connects to two databases, `scott` and `personnel`, and then prints out the connected databases.

```
(setf *default-database-type* :odbc)
(connect "scott")
(connect "personnel" :database-type :odbc)
(print *connected-databases*)
```

### 23.2.4 Connecting to Oracle

For `database-type :oracle`, `connection-spec` conforms to the canonical form described for `connect`. The `connection` part is the string used to establish the connection. When connecting to a local server, it may be the SID, otherwise it is an alias recognized by the names server, or in the `tnsnames.ora` file.

To connect to Oracle via SQL\*Net, `connection-spec` is of the form `username/password@host` where `host` is an Oracle hostname.

Common SQL uses the Oracle Call Interface internally where this is available. For Oracle version 8, Common SQL automatically uses the same API as in LispWorks 4.4. On some platforms, this can also be obtained by using `database-type :oracle8`. Note that the `:oracle8` database type is restricted

## 23.2 Initialization

because it cannot access or manipulate LOBs and all connections must use the same character set.

### 23.2.5 Connecting to ODBC

For *database-type* :`odbc` or :`odbc-driver`, *connection-spec* may take the canonical form described for `connect`, but an additional syntax is also allowed.

`connect` keyword arguments :`encoding`, :`signal-rollback-errors` and :`date-string-format` are all ignored.

#### 23.2.5.1 Connecting to ODBC using a string

*connection-spec* should have one of the forms:

`username/password@dsn`The general form.

`dsn/username/password`For backward compatibility.

The two forms of strings are distinguished by the presence (or absence) of the '@' character. In both forms, *password* can be omitted along with the preceding '/'. Also, *username* can simply be omitted.

Note that this means that "`xyz`" and "`@xyz`" are both interpreted to give the same values (*username* is null, *password* is null, *dsn* is "`xyz`").

#### 23.2.5.2 Connecting to ODBC using a plist

In the plist, the acceptable keywords are :`username`, :`password`, :`dsn` and :`connection`.

:`connection` is a synonym of :`dsn`.

### 23.2.6 Connecting to MySQL

For *database-type* :`mysql`, *connection-spec* may be in the canonical form described for `connect`, but it may also have the extensions described in this section.

In both the string and plist forms of *connection-spec* described below, any part that is omitted defaults to the MySQL default:

<i>username</i>	anonymous user
<i>password</i>	No password
<i>dbname</i>	No default database
<i>hostname</i>	localhost
<i>port</i>	3306 (unless using <i>unix-socket</i> ).

### 23.2.6.1 Connecting to MySQL using a string

*connection-spec* can be a string of the form:

*username*/*password*/*dbname*@*hostname*:*port*

where *port* is a decimal number specifying the port number to use. *port* can be omitted along with the preceding ':':

*hostname* can be omitted. If *port* is omitted too, the '@' can be omitted as well. If *port* is supplied and *hostname* is not supplied, then both the '@' and the ':' are required, for example:

`me/my-password/my-db@:3307`

*hostname* may also specify a unix socket name, which must start with the character '/':

*dbname* may be omitted along with the preceding '/':

*password* may be omitted. If *dbname* is also omitted, the preceding '/' can be omitted too.

*username* may be omitted.

### 23.2.6.2 Connecting to MySQL using a plist

*connection-spec* can be a plist containing (some of) the keywords :*username*, :*password*, :*dbname*, :*hostname*, :*port*, :*connection*, :*unix-socket*.

Each of these keywords may be omitted.

If :*unix-socket* is specified, then none of :*hostname*, :*port* and :*connection* can be specified. If :*hostname* is specified then :*connection* must not be specified. The value supplied for :*hostname* can be a raw hostname, or a

## 23.2 Initialization

string of the form **hostname:port**. If **:connection** is specified then it can be a string conforming to one of these patterns:

<b>hostname</b>	
<b>hostname:port</b>	
<b>:port</b>	
<b>unix-socket</b>	Must start with '/'

That is, the value *connection* supplied in a plist *connection-spec* is interpreted just like the part of a string *connection-spec* following the '@' character.

### 23.2.6.3 Locating the MySQL client library

The MySQL interface to initialize, it must find the appropriate MySQL client library. The special variables \*mysql-library-path\*, \*mysql-library-directories\* and \*mysql-library-sub-directories\* give you control over this.

### 23.2.6.4 Special instructions for MySQL on Mac OS X

Download the 32-bit or 64-bit MySQL package to match your LispWorks image.

The downloadable packages from the MySQL web site contain only static client libraries, but LispWorks needs a dynamic library. You need to create the dynamic library, for example by using the following shell command.

To build the 32-bit dynamic library:

```
gcc -dynamiclib -fno-common \
-o /usr/local/mysql/lib/libmysqlclient_r.dylib \
-all_load /usr/local/mysql/lib/libmysqlclient_r.a -lz
```

To build the 64-bit dynamic library:

```
gcc -m64 -dynamiclib -fno-common \
-o /usr/local/mysql/lib/libmysqlclient_r.dylib \
-all_load /usr/local/mysql/lib/libmysqlclient_r.a -lz
```

This command should be executed as the root user, or some other user with write permission to the `/usr/local/mysql/lib` directory and assumes that

MySQL was installed in `/usr/local/mysql`, which is the location used by the prepackaged downloads.

An alternate way to create a dynamic library is to build MySQL from its source code with the `--enable-shared` flag.

By default, LispWorks expects to find the library either in `/usr/local/mysql/lib` or on the shared library path. This can be overridden by setting the special variable `*mysql-library-directories*`.

By default, LispWorks expects the library to be called `libmysqlclient.*.dylib` and it searches for a library that matches that pattern, where \* is any version number. This search can be avoided by setting `*mysql-library-path*` to something other than the default (`"-lmysqlclient"`), for example, it is possible to force LispWorks to look for version 12 by evaluating

```
(setq *mysql-library-path* "libmysqlclient.12")
```

You can also set `*mysql-library-path*` to a full path, which avoids the need to set `*mysql-library-directories*`.

If the environment variable `LW_MYSQL_LIBRARY` is set, then its value is used instead of the value of `*mysql-library-path*`.

### 23.2.7 Connecting to PostgreSQL

For `database-type :postgresql`, `connection-spec` must be either a string in the format specified by the PostgreSQL libraries or a plist.

#### 23.2.7.1 Connecting to PostgreSQL using a string

If `connection-spec` is a string then it should be in the format specified by

```
http://www.postgresql.org/docs/9.3/static/libpq-connect.html#LIBPQ-CONNSTRING
```

For example,

```
dbname=test user=scott password=tiger host=scandium
```

### 23.2.7.2 Connecting to PostgreSQL using a plist

*connection-spec* can be a plist containing (some of) the keywords `:username` (or `:user`), `:password`, `:dbname`, `:hostname` (or `:host`), `:port`, `:connection`. Each of these keywords may be omitted, but if `:connection` is specified, then `:hostname` and `:port` must not be specified.

The value supplied for `:hostname` can be a raw hostname or a string of the form `hostname:port`. The value supplied for `:port` can be an integer or a string naming a service.

If `:connection` is specified then it can be a string conforming to one of these patterns:

`hostname`

`hostname:port`

The values should not be escaped or quoted: LispWorks will escape and quote it as needed before passing it to the PostgreSQL library.

### 23.2.7.3 Escaping and standard\_conforming\_strings

LispWorks sets the PostgreSQL session variable

`standard_conforming_strings` to `on` to match the escaping that Common SQL uses. Note that this variable is only available in PostgreSQL 8.2 and later, so escaping will not work correctly in older versions of PostgreSQL.

## 23.2.8 Connecting to SQLite.

For `database-type :sqlite`, *connection-spec* is used to specify the filename of the SQLite database. *connection-spec* must be one of the following:

A string.      Specifies the filename as is.

A plist containing `:dbname filename`.

If `filename` is a string, it specifies the filename as is. Otherwise, the value of `(namestring filename)` is used as the filename.

`:memory`      This is equivalent to "`:memory:`" and specifies a private, temporary in-memory database.

:temp	This is equivalent to "" and specifies a private, temporary on-disk database.
-------	---

### 23.2.8.1 Locating the SQLite client library

The special variable `sql:*sqlite-library-path*` contains the FLI shared library name for SQLite. It defaults to `"-lsqlite3"` on non-Windows platforms, which should work if SQLite is installed. On Windows, it defaults to `"sqlite3.dll"`, which requires that DLL to be on the path. Note that 64-bit and 32-bit LispWorks require different DLL files.

The Common SQL SQLite interface assumes that the library is compiled with standard options and that SQLite is not configured in an unusual way. Most importantly, if the threading mode is single-thread (either because the library is compiled as single-thread, or because `sqlite3_config` set it to single-thread), then the Common SQL SQLite interface is not thread-safe anymore. This situation is quite unlikely to happen.

### 23.2.8.2 SQLite string encoding

By default, the connection is opened as a UTF-8 connection (using the C function `sqlite3_open_v2`). The `:encoding` argument to `connect` can have the value `:default`, `:unicode` or `:utf-8` which all use the default (that is, have no effect), and `:utf-16` or `:utf-16-native`, which opens the connection using UTF-16 in the native byte order (using the C function `sqlite3_open16`). It is not obvious in what circumstances UTF-16 is better and it is made available only because the underlying library supports it. When opening as UTF-16, the keywords `:open-mode`, `:threading-mode`, `:uri` and `:vfs` are ignored.

### 23.2.8.3 SQLite connection keywords

The `sqlite-keywords` keyword argument to `connect` allows you to specify several parameters controlling the behavior of the connection. `sqlite-keywords` is a property list, providing values for the SQLite-specific keywords `:open-mode`, `:threading-mode`, `:uri`, `:cache-mode`, `:vfs` or `:uniform-type-per-column`. These keywords affect the connection as follows.

By default, the connection is opened with opening modes create and read-write, which means that the file is created if it does not exist, and the database

can be modified. The SQLite-specific keyword `:open-mode` in *sqlite-keywords* can be used to change this. The value `:readonly` specifies that the file must exist (so `connect` fails if it does not exist) and is opened for reading only (so it is not possible to modify it). The value `:readwrite` means that the file must exist and the database can be modified.

By default, the threading mode of the connection is "serialized" (so it is thread-safe). You can change this by the SQLite-specific keyword `:threading-mode` in *sqlite-keywords*, which can take the values `:multi-thread` or `:serialized`. When the threading mode is `:multi-thread` (rather than `:serialized`), it is not actually thread-safe, and you can access it only on one thread at a time (but it can be accessed from different threads over time). The term "multi-thread" means that you can access different connections at the same time on different threads. `:multi-thread` is probably more efficient, but we do not know by how much.

By default, *connection-spec* can be a URI filename, which is a string starting with "file:" (see <https://www.sqlite.org/uri.html> "URI Filenames In SQLite" for details). Whether this is allowed is controlled by the SQLite-specific keyword `:uri` in *sqlite-keywords*, which defaults to `t`, and can be switched off by passing `:uri nil`.

By default, the connection cache mode is the system default. The SQLite-specific keyword `:cache-mode` in *sqlite-keywords* can be used to change this to either `:private` or `:shared`. See <https://www.sqlite.org/sharedcache.html> "SQLite Shared-cache mode" for details. `:shared` mode probably improves performance if you connect multiple times to the same file.

The SQLite-specific keyword `:vfs` in *sqlite-keywords* can be used to specify the name of the VFS (Virtual File System) that is used. You need to be an expert on SQLite to know when this is useful.

The SQLite-specific keyword `:uniform-type-per-column` in *sqlite-keywords* affects the default type for fields in the results of queries. See "Tables containing a uniform type per column" on page 394.

See "Using SQLite" on page 392 for other SQLite-specific features.

## 23.3 Functional interface

The functional interface provides a full set of Data Manipulation and Data Definition functions. The interface provides a SQL-compatible means of querying and updating the database from Lisp. In particular, the values returned from the database are Lisp values — thus smoothly integrating user applications with database transactions. An embedded syntax is provided for dynamically constructing sophisticated queries through `select`. Iteration is also provided via a mapping function and an extension to the `loop` macro. If necessary, the basic functions `query` and `execute-command` can be called with SQL statements expressed as strings. It is also possible to update or query the data dictionary.

### 23.3.1 Functional Data Manipulation Language (FDML)

The functions available for Data Manipulation and Data Definition are described below.

#### 23.3.1.1 Querying

The function `select` returns data from a database matching the constraints specified. The data is returned, by default, as a list of records in which each record is represented as a list of attribute values.

Database identifiers used in `select` are conveniently specified using the symbolic SQL `[]` syntax. This syntax is enabled by calling `enable-sql-reader-syntax`.

The square bracket syntax assumes that sql symbols are visible. Therefore when using the `[]` syntax, ensure that the current package either is `sql`, or is a package which has the `sql` package on its package-use-list.

For a description of the symbolic SQL syntax see Section 23.5 on page 358. For example, the following is a potential query and its result:

```
(select [person_id] [person surname] :from [person])
=>
((111 "Brown") (222 "Jones") (333 "Smith"))
("PERSON_ID" "SURNAME")
```

### 23.3 Functional interface

In this example, `[person_id]`, `[person_surname]` and `[person]` are database-identifiers and evaluate to literal SQL. The result is a list of lists of attribute values. Conversely, consider

```
(select [surname] :from [person] :flatp t)
=>
("Brown" "Jones" "Smith")
("SURNAME")
```

In this case the result is a simple list of surname values because of the use of the `flatp` keyword. The `flatp` keyword only works when there is one column of data to return.

In this example we use `*` to match all fields in the table, and then we use the `result-types` keyword to specify the types to return:

```
(select [*] :from [person])
=>
((2 111 "Brown") (3 222 "Jones") (4 333 "Smith"))
("ID" "Person_ID" "Surname")

(select [*] :from [person] :result-types '(:integer :string
:string))
=>
((2 "111" "Brown") (3 "222" "Jones") (4 "333" "Smith"))
("ID" "Person_ID" "Surname")
```

If you want to affect the result type for a specified field, use a type-modified database identifier. As an example:

```
(sql:select [Person_ID :string] [Surname] :from [person])
=>
(("111" "Brown") ("222" "Jones") ("333" "Smith"))
("PERSON_ID" "SURNAME")
```

With `database-type :mysql`, further control over the values returned from queries is possible as described in “Types of values returned from queries” on page 377.

In this final example the `:where` keyword is used to specify a condition for returning selected values from the database.

```
(select [surname] :from [person] :where [= [person_id] 222])
=>
(("Jones"))
("SURNAME")
```

To output the results of a query in a more easily readable tabulated way, use the function `print-query`. For example the following call prints two even columns of names and salaries:

```
(print-query [select [surname] [income] :from [employee]]
            :titles '("NAME" "SALARY"))

NAME      SALARY
Brown    22000
Jones    45000
Smith    35000
```

### 23.3.1.2 Modification

Modifications to the database can be done using the following functions; `insert-records`, `delete-records` and `update-records`. The functions `commit`, `rollback` and the macro `with-transaction` are used to control transactions. Although `commit` or `rollback` may be used in isolation it is advisable to do any updates inside a `with-transaction` form instead. This provides consistency across different database transaction models. For example, some database systems do not provide an explicit “start-transaction” command while others do. `with-transaction` allows user code to ignore database-specific transaction models.

The function `insert-records` creates records in a specified table. The values can be either specified directly with the argument `values` or in the argument `av-pairs`, or they can be the result of a query specified in the `query` argument. The attributes can be specified with the argument `attributes` or in the argument `av-pairs`.

If `attributes` is supplied then `values` must be a corresponding list of values for each of the listed attribute names. For example, both:

```
(insert-records :into [person]
                :attributes '(person_id income surname occupation)
                :values '(115 11000 "Johnson" "plumber"))
```

and:

### 23.3 Functional interface

```
(insert-records :into [person]
                      :av-pairs `((person_id 115)
                                  (income 11000)
                                  (surname "Johnson")
                                  (occupation "plumber")))
```

are equivalent to the following SQL:

```
INSERT INTO PERSON
  (PERSON_ID, INCOME, SURNAME, OCCUPATION)
VALUES (115, 11000, 'Johnson', 'plumber')
```

If *query* is provided, then neither *values* nor *av-pairs* should be. In this case the attribute names in the query expression must also exist in the insertion table. For example:

```
(insert-records :into [person]
                :query [select [id] [firstname] [surname]
                        :from [manager]]
                :attributes '(person_id firstname surname))
```

To delete or alter those records in a table which match some condition, use `delete-records` or `update-records`.

#### 23.3.1.3 Caching of table queries

Operations which add or modify records sometimes need to perform an internal query to obtain type information for the relevant attributes. In principle it is possible for the database schema to change between update operations, and hence this query is run for each update operation. This can be a significant overhead.

For tables which are guaranteed to have a constant schema, you can optimize performance by adding a cache of these internal query results, using the function `cache-table-queries`. This can also be used to reset the cache if the table schema is actually altered. To control the default caching behavior throughout every database connection, you can set the variable `*cache-table-queries-default*`.

### 23.3.1.4 Transaction handling

A transaction in SQL is defined as *starting from the connect, or from a commit, rollback or data-dictionary update and lasting until a commit, rollback, data-dictionary update or a disconnect command.*

The macro **with-transaction** executes a body of code and then does a commit, unless the body failed in which case it does a rollback. Using this macro allows your code to cope with the fact that transactions may be handled differently in the different vendor implementations. Any differences are transparent if the update is done within a **with-transaction** form.

**Note:** Common SQL opens an ODBC database in manual commit mode, so that **with-transaction** and **rollback** take effect.

Applications should perform all database update operations in a **with-transaction** form (or follow them with **commit** or **rollback**) in order to safely commit or discard their changes. This applies to operations that modify either the data or the schema.

The following example shows a series of updates to an employee table within a transaction. This example would commit the changes to the database on exit from **with-transaction**. This example inserts a new record into the **emp** table, then changes those employees whose department number is 40 to 50 and finally removes those employees whose salary is more than 300,000.

```
(connect "personnel")

(with-transaction
  (insert-records :into [emp]
    :attributes '(empno ename job deptno)
    :values '(7100 "ANDERSON" "SALESMAN" 30))
  (update-records [emp]
    :attributes [deptno]
    :values 50
    :where [= [deptno] 40])
  (delete-records :from [emp]
    :where [> [sal] 300000]))
```

To commit or roll back all changes made since the last commit, use the functions **commit** or **rollback**.

### 23.3.1.5 Iteration

Common SQL has three iteration constructs: a `do` loop, a mapping function, and an extension to the Common Lisp `loop` macro.

The macros `do-query` and `simple-do-query` repeatedly execute a piece of code within the scope of variables bound to the attributes of each record resulting from a query.

The function `map-query` maps a function across the results of a query and returns its result in a sequence of a specified type, like the Common Lisp `map` function.

Common SQL provides an extension to the ANSI Common Lisp macro `loop` which is a clause for iterating over query results. The syntax of the clause is:

```
{for|as} var [type-spec] being
  {the|each}{tuples|tuple}
  {in|of} query-expression
```

`query-expression` can be a string, a `sql-expression-object` (a result of the "[...]" syntax) or a `prepared-statement`.

The more general word `tuple` is used so that it can also be applied to the object-oriented case. In the functional case, `tuple` is synonymous with `record`.

Each iteration of the loop assigns the next record of the table to the variable `var`. The record is represented in Lisp as a list. Destructuring can be used in `var` to bind variables to specific attributes of the records resulting from `query-expression`. In conjunction with the panoply of existing clauses available from the `loop` macro, the new iteration clause provides an integrated report generation facility.

Suppose the name of everyone in an employee table is required. This simple query is shown below using the different iteration method. The function `map-query` requires `flatp` to be specified; otherwise each name would be wrapped in a list.

```
(do-query ((name) [select [ename] :from [emp]])
  (print name))
```

```
(map-query
  nil
  #'(lambda (name) (print name))
  [select [ename] :from [emp] :flatp t])

(loop for (name)
      being each tuple in
      [select [ename] :from [emp]]
      do
  (print name))
```

The following extended `loop` example binds, on each record returned as a result of the query, `name` and `salary`, accumulates the salary, and for salaries greater than 2750 increments a count, and prints the details. Finally, the average salary is printed.

```
(loop for (name salary) being each record in
  [select [ename] [sal] :from [emp]]
  initially (format t "~&~20A~10D" 'name 'salary)
  when (and salary (> salary 2750))
    count salary into salaries
    and sum salary into total
    and do (format t "~&~20A~10D" name salary)
  else
    do (format t "~&~20A~10D" name "N/A")
  finally
  (format t "~2&Av Salary: ~10D" (/ total salaries)))
```

### 23.3.1.6 Specifying SQL directly

Sometimes it is necessary to execute vendor-specific SQL statements and queries. For these occasions Common SQL provides the functions `query` and `execute-command`. They can also be used when the exact SQL is known in advance and thus the square bracket syntax is not needed. The query expression can be a string, a `sql-expression-object` (a result of the "[...]" syntax) or a `prepared-statement`.

The function `query` runs a SQL query on a database and returns a list of values like `select` (see “Querying” on page 346). It also returns a list of the field names selected.

`execute-command` is the basic function which executes any SQL statement other than a query. It can run a stored procedure, as described in `execute-command`, page 1567.

### 23.3 Functional interface

#### 23.3.1.7 Building vendor-specific SQL

Common SQL does not provide a general interface to vendor-specific syntax.

There are two approaches you can take with SQL such as this:

```
SELECT B.PARTY_CODE_ALIAS, A.VALUE FROM CODES A, CODE_ALIASES B
    WHERE A.DOMAIN=B.CODE_DOMAIN(+) AND A.VALUE=B.CODE_VALUE(+)
        AND B.PARTY_ID(+)=<party_id>
```

1. Construct the string as above and then call `query` as described in “Specifying SQL directly” on page 352.
2. Use `sql-expression` to construct the vendor-specific pieces of the SQL.  
The above expression can be written like this:

```
(sql:select [b party_code_alias] [a value]
            :from '([codes a] [codes_aliases b])
            :where [and [= [a domain]
                        (sql:sql-expression
                            :string "B.CODE_DOMAIN(+))"]
                        [= (sql:sql-expression
                            :string "B.PARTY_ID(+)" PARTY-ID)])')
```

#### 23.3.2 Functional Data Definition Language (FDDL)

Functions in the FDDL may be used to change or query the structure of the database.

##### 23.3.2.1 Querying the schema

The functions `list-tables`, `list-attributes`, `attribute-type` and `list-attribute-types` return information about the structure of a database.

##### 23.3.2.2 FDDL Querying example

This example shows you how to query the type of the `ename` attribute of the `emp` table.

```
(attribute-type [ename] [emp]) -> :char
```

### 23.3.2.3 Modification

You may create or drop (delete) tables using the functions `create-table` and `drop-table`.

Create or drop indexes using the functions `create-index` and `drop-index`.

To create or drop a view (that is, a derived table based on a query) use the functions `create-view` and `drop-view`.

## 23.4 Object oriented interface

This section describes the object-oriented interface to SQL databases using specialized CLOS classes. These classes have `standard-db-object` as one of their superclasses and have a common metaclass which provides the specialized behavior for mapping subclasses of `standard-db-object` onto records in the database. A class of this kind is created using `def-view-class`.

### 23.4.1 Object oriented/relational model

In the simple case, a class maps onto a database table, an instance of the class maps onto a record in the table, and a slot in the class maps onto an attribute in the table.

In general, however, a class maps onto a database view, an instance of the class maps onto a collection of records in the view, and a slot in the class is either:

- A *base slot* that maps onto an attribute in the view
- A *join slot* that points to a list of other view-class instances

If an instance maps onto more than one record in the view then for each record, all the key attributes from each table in the view are the same.

#### 23.4.1.1 Inheritance for View Classes

It is not possible to inherit from a class that was defined by `def-view-class`. All of the slots need to be in the same class (and hence also in the same SQL table).

### 23.4.2 Object-Oriented Data Definition Language (OODDL)

The OODDL lets you define a mapping between the relational and object-oriented worlds to be defined. Through the mapping a CLOS object can effectively denote a collection of records in a database view, and can contain pointers to other view-based CLOS objects. The CLOS object makes explicit an object implicitly described by the flat relational values.

The mapping is defined using the macro `def-view-class`. This extends the syntax of `defclass` to allow special *base slots* to be mapped onto the attributes of database views (presently single tables). When you submit a `select` query that names a View Class (that is, a class defined by `def-view-class`), then the corresponding database view is queried, and the slots in the resulting instances are filled with attribute values from the database.

It is also possible to create *join slots* and *virtual* (ordinary) *slots*.

All the special slots are distinguished by a modified set of class and slot options. The special slots and their options are described in more detail under `def-view-class` in the *LispWorks Reference Manual*.

**Note:** `def-view-class` defines a Lisp view of an underlying database table. It is a similar concept to that of SQL VIEWS, but does not interact with them.

You can create a table based on a View Class using the function `create-view-from-class` and delete it using the function `drop-view-from-class`.

#### 23.4.2.1 Example View Class definition

The following example shows a View Class corresponding to the traditional employees table, with the employee's department given by a join with the departments table. See `def-view-class`, page 1551 for a description of the slot options.

```
(def-view-class employee (standard-db-object)
  ((employee-number :db-kind :key
                    :column empno
                    :type integer)
   (employee-name :db-kind :base
                  :column ename
                  :type (string 20)
                  :accessor employee-name)
   (employee-department :db-kind :base
                         :column deptno
                         :type integer
                         :accessor employee-department)
   (employee-job :db-kind :base
                 :column job
                 :type (string 9))
   (employee-manager :db-kind :base
                      :column mgr
                      :type integer)
   (employee-location :db-kind :join
                       :db-info (:join-class department
                                         :retrieval :deferred
                                         :set nil
                                         :home-key employee-department
                                         :foreign-key department-number
                                         :target-slot department-loc)
                       :accessor employee-location))
   (:base-table emp))
```

The `def-view-class` macro allows elements or lists of elements to follow `:home-key` and `:foreign-key`. The elements can be symbols, `nil`, strings, integers or floats.

This syntax means that an object from the join class is only included in the join slot if the values from `home-key` are `equal` to the values in `foreign-key`, in order. These values are calculated as follows:

- If the element in the list is a symbol it is taken to be a slot name and the value of the slot is used
- Otherwise the element is taken to be the value

Note that some database vendors may have short maximum identifier lengths. The CLOS interface uses constructed alias names for tables in its SQL queries, and long table names or long class names may cause the constructed aliases to exceed the maximum identifier length for a particular vendor.

### 23.4.3 Object-Oriented Data Manipulation Language (OODML)

The OODML is designed to be powerful and expressive, while remaining familiar to users of the FDML. To achieve this aim, some of the functions and macros in the SQL interface have been *overloaded* — particularly the `select` function and the iteration constructs.

The function `select` is common across the both the functional and object-oriented SQL interfaces. If its first argument, `selections`, refers to a View Class by supplying its symbolic name then the select operation becomes object-oriented and it returns a list of instances instead of a list of attributes.

A subsequent equivalent `select` call will return the same (`eq1`) instances. The `:refresh` argument can be used to ensure that existing instances get updated with any changed data. If such an update requires action by your application, then add methods on the generic function `instance-refreshed`.

In a View Class `select` call, the symbol `slot-value` is a valid SQL operator for use within the `:where` argument.

To find the View Classes for a particular database, use the function `list-classes`.

To manipulate data via a View Class, that is to modify the records corresponding to instances of the View Class, using the generic functions `update-records-from-instance`, and `update-record-from-slot`.

To delete records corresponding to instances of the View Class, use the generic function `delete-instance-records`.

To update existing instances of a View Class when data is known to have changed, use the generic functions `update-slot-from-record` and `update-instance-from-records`.

#### 23.4.3.1 Examples

```
[select 'employee']
-> #<SQL-OBJECT-QUERY (EMPLOYEE) >
```

```
(select 'employee
       :where [= [slot-value 'employee 'employee-job]
              "SALESMAN"])
((#<db-instance EMPLOYEE 8067092>
  (#<db-instance EMPLOYEE 8069536>
    (#<db-instance EMPLOYEE 8069176>))

(list-classes)
(#<db-class EMPLOYEE> #<db-class DEPARTMENT>)
```

### 23.4.3.2 Iteration

The object-oriented SQL interface has the same three iteration constructs as the functional interface (see Section 23.3.1.5 on page 351): a `do-loop`, a mapping function, and an extension to the Common Lisp `loop` macro. However, in this case, the iteration focus is not a tuple of attributes (that is, a record), but a tuple of instances. For example:

```
(loop for (jones company) being the tuples in
      [select 'person 'organization
      :where [= [slot-value 'person 'surname] "Jones"]]
      do (format t "~A ~A ~%" 
                 (slot-value jones 'forename)
                 (slot-value company 'short-name)))
```

**Note:** Instances may denote many database records, and hence the effective iteration focus in this case is a tuple of sets of tuples of attributes.

### 23.4.3.3 Garbage collection of view instances

View instance objects are not released for garbage collection (GC) until the connection is closed. This is because they are referenced by the CLOS object representing the database connection. This is to ensure that they can reliably be compared by `eq`.

## 23.5 Symbolic SQL syntax

Common SQL supports a symbolic query syntax across both the functional and object-oriented interface layers. It allows SQL and Common Lisp expressions to be mixed together — with as much processing as possible done at compile-time. Symbolic SQL expressions are read as square-bracketed lists to

## 23.5 Symbolic SQL syntax

distinguish them from Lisp expressions. However, each can be nested within the other to achieve the desired result.

By default, this reader syntax is turned off. To turn it on see Section 23.5.3 on page 370.

### 23.5.1 The “[...]" Syntax

The square bracket syntax for the SQL interface is heavily overloaded to provide the most intuitive behavior in all situations. There are three uses of square brackets:

1. To enclose a database identifier
2. To construct a SQL string representing a symbolic expression
3. To enclose an SQL expression directly

Each of these uses is demonstrated below.

#### 23.5.1.1 Enclosing database identifiers

Database identifiers are specified in the "[...]" syntax using the following rules:

There must be one, two or three Lisp forms inside the square brackets. The first form must be a symbol, string or a recursive database identifier (that is, another square brackets expression). The second form, if present, must be a symbol or a string. The third form, if present, must be a keyword.

The case with a single form that is a string is special, and is interpreted as a direct SQL expression rather than an identifier (see “Enclosing a SQL expression directly” on page 366 below).

When a string or a symbol is used to specify all or part of the identifier and the string (or name of the symbol) cannot be used as an identifier (because it contains special characters or matches a SQL reserved word), then it is wrapped with double quotes in the resulting SQL.

If there is more than one form inside the square brackets, and the first form is a symbol that is recognized as a SQL operator or a pseudo-operator, then the expression is interpreted as an operation rather than as an identifier (see the following sections).

The first form is always interpreted as specifying a string that is part or all of the identifier. For a symbol, it is the symbol name and for a recursive identifier it is the string that would be generated for this identifier. In the examples below, the text following the => (and optionally up to the semicolon) shows what is generated for the resulting SQL.

If there is only one form, it specifies the full name of the identifier. For example:

```
[foo]           => FOO
["foo"]         => foo
[[foo]]         => FOO
[W%((jj))      => W%((jj); single form string not quoted.
```

If the second form is a string and the first form is not a string, then the first form specifies the name of the identifier and the second form specifies an alias. In this case there must not be a third form. The alias identifier is useful for giving tables aliases in the `from` part of the SQL `select` statement:

```
[foo "AA"]     => FOO AA
[[foo aa] "bb"]
                => FOO.AA bb ; first form is recursive.
```

If there is a third form, or the second form is not keyword, or the first form is a string, then the second form specifies an identifier qualified by the first form, that is they are combined with a period in the middle:

```
[foo aa]       => FOO.AA
[foo aa :integer]
                => FOO.AA ; with type :integer (below).

["foo" "AA"]
                => foo.AA ; compare to [foo "AA"] above.
```

If there are only two forms and the second form is a keyword, or there are three forms, then the second form (in the two form case) or the third form (in the three form case) specifies a type associated with the identifier. The type

### 23.5 Symbolic SQL syntax

does not affect the SQL statement that the database sees. It is used when the identifier is part of the selection list, to tell Common SQL what type the value should be. Such identifiers should appear only in the selection list of queries.

```
[ColumnName :integer]
=> COLUMNNNAME ; type :integer.

[[TableName ColumnName] :string]
=> TABLENAME.COLUMNNNAME ; type :string.

[TableName ColumnName :string]
=> TABLENAME.COLUMNNNAME ; type :string
(same as previous).
```

Inside select (which is recognized as a SQL operator):

```
[select [id :integer] [name :string] :from [TableName]]
=> SELECT ID, NAME FROM TABLENAME ; interpret
ID as an integer and NAME as a string.
```

Notes:

- You can specify both an alias and a type by specifying the identifier recursively in the first form:

```
[[TableName ColumnName] "MyAlias" :string]
=> TABLENAME.COLUMNNNAME MyAlias ; type
:string
```

- Recursion through the first form also allows you to add qualifiers as needed:

```
[[[[CatalogName SchemaName] TableName] ColumnName]
"MyAlias" :string]
=> CATALOGNAME.SCHEMANAME.TABLE-
NAME.COLUMNNNAME MyAlias ; type :string.
```

- Because a string as single form is not quoted, it allows you to insert any SQL directly. For example, in the first expression below the string which contains illegal characters is quoted, but in the second example the

string appears as a single form in the recursive identifier, so is not quoted:

```
[ "W%((jj" aa]
=> "W%((jj).AA ; string is quoted.

[[ "W%((jj"] . aa]
=> W%((jj.AA ; string not quoted because it is a single
form.
```

- Evaluating an expression in "[...]" syntax returns an object of type `sql-expression-object`.

### 23.5.1.2 Specifying the type of retrieved values.

When you use a keyword to specify the type of an expression as described in “Enclosing database identifiers” on page 359, you are telling common SQL that the values retrieved for this expression should be of a specific type. For example, if you call:

```
(sql:select [name :string] :from [TableName])
```

then the `:string` keyword tells common SQL that the values for `name` should be strings.

There are four keywords that are supported by all common SQL backends: `:string`, `:integer`, `:double-float` and `:single-float`. For each of these keywords, the values are mapped to the matching Common Lisp type. If this is not possible, the value is returned as `nil`.

Note that if you specify a keyword that is incompatible with the type in the database column then either an error is signaled or all returned values will be `nil`.

The keyword `:int` is accepted as an alias for `:integer`.

The keyword `:binary` is supported by most of backends (except Microsoft Access and PostgreSQL). The value that is returned for `:binary` is an array with element type (`unsigned-byte 8`). On Oracle, `:binary` can be used only for columns of binary type, so it is only useful when you want to retrieve the

## 23.5 Symbolic SQL syntax

contents of a BLOB directly, because for plain RAW columns it is the default anyway. Other backends allow you to retrieve at least strings as binary values.

Other keywords are supported by some of the backends, and are documented in the backend specific sections.

### 23.5.1.3 Symbolic expression of SQL operators

When the first form in the square brackets is a symbol that is one of the SQL operators listed below, the expression is interpreted as an operation. For example:

```
[any '(3 4)] -> #<SQL-VALUE-EXP "(ANY (3,4))">
```

Similarly with two argument operators:

```
[> [baz] [beep]]
-> #<SQL-RELATIONAL-EXP "(BAZ > BEEP)">
```

The `select` statement itself may be prepared for later query execution using the `[]` syntax. For example:

```
[select [person_id] [surname] :from [person]]
```

This form results in a SQL expression, which could be bound to a Lisp variable and later given to `query` to execute. For example:

```
[select [foo] [bar *]
       :from '([baz] [bar])
       :where [or [= [foo] 3]
              [> [baz.quux] 10]]]
->
#<SQL-QUERY
  "(SELECT FOO,BAR.* FROM BAZ,BAR
   WHERE ((FOO = 3)
          OR (BAZ.QUUX > 10)))">
```

Strings can be inserted in place of database identifiers within a `select`:

```
[select [foo bar] [baz]
      :from '([foo] [quux])
      :where [or [> [baz] 3]
              [like [foo bar] "SU%"]]
->
#<SQL-QUERY:
  "(SELECT FOO.BAR,BAZ
   FROM FOO,QUUX
   WHERE ((BAZ > 3)
          OR (FOO.BAR LIKE 'SU%')))">
```

Any non-constant included gets filled in at run time, for example:

```
[> [foo] x]
```

when macroexpanded reads as

```
(SQL-> #<SQL-IDENT "FOO"> x)
```

which constructs the actual SQL string at run time.

Any arguments to a SQL operator that are Lisp constants are translated to the matching SQL construct at compile-time, for example:

```
"foo" -> "'foo'"
3 -> "3"
'("this" 5 "that") -> "('this', 5, 'that')"
'xyz -> "XYZ"
```

SQL operators which are supported are `null`, `exists`, `*`, `+`, `/`, `-`, `like`, `substr`, `and`, `or`, `not`, `in`, `all`, `any`, `some`, `|`, `=`, `<`, `>`, `>=`, `<=`, `<>`, `order-by`, `count`, `max`, `min`, `avg`, `sum`, `minus`, `nvl`, `distinct`, `except`, `intersect`, `union`, `slot-value`, `between` and `userenv`. There are also pseudo operators for calling database functions (see “Calling database functions” on page 365).

The general syntax is: [`<operator> <operand> ...`], for instance:

```
(sql:select [count [*]] :from [emp])
```

The operand can itself be a SQL expression, as in the following example:

## 23.5 Symbolic SQL syntax

```
(sql:create-table [company]
  '(([name] (varchar 20) not-null)))

(loop for company in '("LispWorks Ltd"
  "Harlequin"
  "Oracle"
  "Rover"
  "Microsoft")
  do
  (sql:insert-records :into [company]
    :av-pairs `(([name] ,company)))))

(sql:create-table [person]
  '(([surname] (varchar 20) not-null)
  ([firstname] (varchar 20) not-null)))

(loop for person in '(("Joe" "Bloggs")
  ("Fred" "Smith")
  ("Rover" "the Dog")
  ("Fido" "the Dog"))
  do (sql:insert-records :into [person]
    :av-pairs
    `(([firstname] ,(car person))
    ([surname] ,(second person)))))

(sql:select [name]
  :from [company]
  :where [= [name]
    [any [select [surname]
      :from [person]]]])

(sql:select [surname]
  :from [person]
  :set-operation [union [select [firstname]
    :from [person]]]))
```

### 23.5.1.4 Calling database functions

An arbitrary function can be included in the SQL using the pseudo operator `sql-function`. The first argument is the function name and the rest are its arguments, for example:

```
(select [sql-function "COS" [age]] :from [EMPLOYEES])
```

```
(insert-records
  :into [atable]
  :attributes '(a b)
  :values
  (list 1 [sql-function "TO_DATE" "02/06/99" "mm/DD/RR"])))
```

Also you can call SQL infix operators using the pseudo operators `sql-boolean-operator` and `sql-operator`.

### 23.5.1.5 Enclosing a SQL expression directly

An SQL expression can simply be enclosed directly in the square bracket syntax, as shown below.

Creating a full query (which can be used as argument to `query`):

```
["SELECT FOO, BAR FROM BAZ"]
-> #<SQL "SELECT FOO, BAR FROM BAZ">
```

Using an non-portable function condition in `:where`:

```
(sql:select [*] :from ["aTable"]
           :where ["non_portable_function() > 89"])
```

### 23.5.1.6 SQL string literals

SQL string literals can be used as arguments to operators, for example with a constant Lisp string:

```
[= [name] "John"]
```

or with a Lisp expression that evaluates to string:

```
(defun find-person-age (name)
  (car (select [age] from [table]
               :where [= [name] name])))
```

where the argument `name` is a string.

However, Microsoft SQL Server (which can be used via ODBC) requires the N syntax for string literal that are not entirely ASCII, or contain characters that are not recognized by the server code page. (The N syntax prefixes the string literal by the character N, for example `N'Greek'`, rather than `'Greek'`.)

Although this syntax is part of the SQL standard, not all SQL backends accept it (in particular, SQLite and Microsoft Access (via ODBC) do not). Thus the

### 23.5 Symbolic SQL syntax

decision whether to use the N syntax needs to be made at run time and requires the SQL backend (which is represented by the database object that `connect` returns). By default, the symbolic SQL syntax does not use the N syntax, but the special pseudo-operator `string` can be used to override this. `string` takes a required argument, which must be a string, and an optional argument, a database (which defaults to `*default-database*`), and produces the appropriate syntax for that database. The example above can be written using `string` like this:

```
(defun find-person-age (name)
  (car (select [age] from [table]
               :where [= [name] [string name]])))
```

The same database must be used for the `string` pseudo-operator and the function/macro that uses the resulting expression. In the example above, the function is `select` and the database not specified at all, so both `string` and `select` will use `*default-database*`. This restriction means that the `string` pseudo-operator cannot be used to generate a pre-existing expression, which is otherwise possible with the symbolic SQL syntax. For example, your code might contain:

```
(defvar *match-name-starting-with-cf* [like [name] "CF%"])
```

which defines `*match-name-starting-with-cf*` at load time, and then use it elsewhere:

```
(defun some-function (arg1 ...)
  ..
  (select [*] :from [table]
          :where *match-name-starting-with-cf*)
  ..
  )
```

But if you use `[string "CF%"]` in the `defvar`, it will try to use the database at load time, which is normally before the database is connected.

You can perform approximately what the `string` pseudo-operator does by using `string-prefix-with-n-if-needed`:

```
(let ((maybe-qualified
        (string-prefix-with-n-if-needed name)))
  (car (select [age] from [table]
               :where [= [name] maybe-qualified])))
```

Another option is to set the variable `*use-n-syntax-for-non-ascii-strings*` to `t` at compile time, which causes all string literals that are not entirely ASCII to be produced with N syntax. That would generate code that will work with almost all SQL backends, but not with SQLite or Microsoft Access (which do not support the N syntax). The advantage is that, if you have a large number of string literals, then you do not have to change them all: you just need to recompile your code with `*use-n-syntax-for-non-ascii-strings*` set to `t`.

### 23.5.2 Programmatic interface

In some cases it is necessary to build SQL-expressions dynamically under program control.

The function `sql-operation` returns the SQL expression for an operator applied to its arguments. It also supports building SQL expressions which contain arbitrary SQL functions using the pseudo operators `sql-function`, `sql-operator` and `sql-boolean-operator`. For examples see `sql-operation`, page 1660.

The function `sql-expression` makes a SQL expression from the given keywords. This is equivalent to the first and third uses of the `[]` syntax as discussed in Section 23.5.1 on page 359.

The function `sql-operator` returns the Lisp symbol for a SQL operator.

The function `sql` makes SQL out of the arguments supplied. Each argument to `sql` is turned into SQL and then the args are concatenated with a single space between each pair. A Lisp string maps to the same characters enclosed between single quotes (this corresponds to a SQL string constant). `nil` maps to "NULL", that is, a SQL null value. Symbols and numbers map to strings. A list maps to a parenthesised, comma-separated expression. A vector maps to a comma-separated expression, which allows the easy generation of SQL lists that require no parentheses such as table lists in select statements.

The rules for the conversion are fully specified in `sql`, page 1642.

### 23.5.2.1 Examples

The following example function, taken from the object-oriented SQL interface layer, makes a SQL query fragment that finds the records corresponding a CLOS object (using the slots as attributes), when built into the *where*-clause of an updating form.

```
(let* ((class (class-of object))
       (key-slots (db-class-keyfields class)))
  (loop
    for key in key-slots
    for slot-name = (slot-definition-name key)
    for slot-type = (db-slot-definition-type key)
    collect
      [= (make-field-name class key)
        (lisp-to-sql-format
          (slot-value object slot-name)
          (if (listp slot-type)
              (car slot-type)
              slot-type))])
  into cols
  finally (apply (sql-operator 'and) cols)))
->
#<SQL-RELATIONAL-EXP "(EMP.EMPNO = 7369)">
```

Here is another example that produces a SQL *select* statement:

```
(sql-operation 'select
  (sql-expression :table 'foo
                  :attribute 'bar)
  (sql-expression :attribute 'baz)
:from (list
        (sql-expression :table 'foo)
        (sql-expression :table 'quux))
:where (sql-operation 'or
            (sql-operation '>
                (sql-expression :attribute 'baz)
            3)
            (sql-operation 'like
                (sql-expression :table 'foo
                                :attribute 'bar)
                "SU%")))
->
#<SQL-QUERY "SELECT FOO.BAR,BAZ FROM FOO,QUUX
 WHERE ((BAZ > 3) OR (FOO.BAR LIKE 'SU%'))">
```

### 23.5.3 Utilities

The function `enable-sql-reader-syntax` switches square bracket syntax on and sets the state so that `restore-sql-reader-syntax-state` restores the syntax again if it is subsequently disabled. The function `disable-sql-reader-syntax` switches square bracket syntax off and sets the state so that `restore-sql-reader-syntax-state` disables the syntax again if it is subsequently enabled.

The functions `locally-enable-sql-reader-syntax` and `locally-disable-sql-reader-syntax` switch square bracket syntax on and off, but do not change the state restored by `restore-sql-reader-syntax-state`. The intended use of these is in a file:

```
#.(locally-enable-sql-reader-syntax)
  <code using [...]>
#.(restore-sql-reader-syntax-state)
```

## 23.6 Working with date fields

This section describes particular issues around using datetime database fields via Common SQL. Note: SQLite does not support date fields at all.

See also “Types of values returned from queries” on page 377 for information specifically about returning datetime values from MySQL.

### 23.6.1 Testing date values

Compare DATE values by formatting the date as a string in a date format that the database can parse. For example:

```
(sql:select * :from [Table] :where [= [Date] "2005-12-25"])
```

Note that it is not possible to lookup date values in the database using numeric values. This is because:

1. Common SQL cannot know that the field will be a date field until the results are returned, and
2. the database probably does not know about Common Lisp universal time.

## 23.6 Working with date fields

To convert between universal time and standard SQL DATE or TIMESTAMP string, you can use the functions `encode-db-standard-date`, `encode-db-standard-timestamp`, `decode-to-db-standard-date` and `decode-to-db-standard-timestamp`. Note that the database may have non-standard date format, in which case you will need to either format the string yourself, or on Oracle tell the database to use the standard format by passing `date-string-format` to `connect`.

### 23.6.2 DATE returned as universal time

By default Common SQL converts DATE values to Common Lisp universal times. Therefore code like this returns Common Lisp universal times (that is, integers) where `MyDate` is a DATE field type:

```
(sql:select [MyDate] :from [MyTable] :where [= [id] 1])
```

#### 23.6.2.1 Timezone of returned DATEs

Common SQL creates universal time values from DATE fields assuming that the database contains times in Coordinated Universal Time (UTC). That is, as if by passing `time-zone 0` to `encode-universal-time`. To decode the values consistently with this encoding, pass `time-zone 0` to `decode-universal-time`.

If the database contains times in a different timezone, then the integer `time-zone` needs to be adjusted by adding an appropriate multiple of 3600 before calling `decode-universal-time`.

### 23.6.3 DATE returned as string

Instead of universal time integers, you can obtain strings formatted by the database by modifying the `MyDate` database identifier, adding `:string` like this:

```
(sql:select [MyDate :string] :from [MyTable] :where [= [id] 1])
```

This avoids the overhead of converting DATEs to universal times and so may improve performance of your application.

See `select`, page 1634 for details.

### 23.6.4 Using universal time format

If the database is only accessed via Common SQL and you want to use the universal time date format, then you might consider using an INTEGER column containing universal time values instead of a DATE column.

## 23.7 SQL I/O recording

It is sometimes convenient to simply monitor the flow of commands to, and results from, a database. A number of functions are provided for this purpose.

The functions operate on two stream collections (*broadcast streams*) — one each for commands and results. They allow the recording to be started and stopped, checked, or recorded on further individual streams. By default, both commands and results recording is printed only to `*standard-output*`.

For details, see the reference pages for `start-sql-recording`, `stop-sql-recording`, `sql-recording-p`, `list-sql-streams`, `sql-stream`, `add-sql-stream` and `delete-sql-stream`.

## 23.8 Error handling in Common SQL

All errors generated by Common SQL are of type `sql-user-error` or `sql-database-error`. You can test for these conditions and their subtypes in your error handlers.

### 23.8.1 SQL condition classes

An `sql-user-error` is an error inside Lisp.

An `sql-database-error` is an error inside the database interface that Lisp uses.

The following are subclasses of `sql-database-error`:

`sql-database-data-error`

An error with the data given. It signifies an error that must be fixed for the code to work.

`sql-timeout-error`

## 23.9 Using MySQL

Signifies an error that is a result of other users using the same database. It means the code can work without change, once the other users stop using the database.

### `sql-connection-error`

An error with the connection to the RDBMS.

The following are subclasses of `sql-connection-error`:

#### `sql-timeout-error`

A timeout with some operation.

#### `sql-fatal-error`

An error which means that the connection is no longer usable.

**Note:** In general, the documentation for the various supported databases make it difficult to decide which error code should be made into which of the above condition class, and we probably get many of these wrong. If you find errors that seem to be signaled with the wrong condition class, please report them to Lisp Support, including the full printout of the condition, and we will fix it.

### 23.8.2 Database error accessors

Three functions are provided which access slots of `sql-database-error`, allowing you to discover more about the actual error that occurred.

`sql-error-error-id` and `sql-error-secondary-error-id` return primary and secondary error identifiers. If you use these, please read the detailed description in `sql-database-error`, page 1643.

`sql-error-database-message` is a string (maybe `nil`) returned by the foreign code.

## 23.9 Using MySQL

This section describes particular issues in Common SQL with MySQL databases.

### 23.9.1 Connection specification

See “Connecting to MySQL” on page 339 for information about MySQL specific extensions for the *connection-spec* passed to `connect`.

### 23.9.2 Case of table names and database names

MySQL is case sensitive on table names and database names when the server is on a Unix machine. MySQL does not automatically change raw names to uppercase as specified by the SQL standard. However, Common SQL is geared towards uppercasing all names, so this may cause some mismatches. In general, Common SQL uppercases strings, and uses symbol names, which are normally uppercase, as-is.

One solution, possible only if you control the naming of tables and databases, is to make them all have the same case. If this is uppercase, that suffices. If it is lowercase, you need to set the variable `lower_case_table_names` in the configuration of the server.

If you cannot make all the names the same case, you have to get the case right. This can be achieved in several ways:

1. Specify tables names using strings, for example:

```
(sql:select [*] :from ["TableNamewithVARIABLEcase"])
```

Note that this does not work in LispWorks 4.4 and previous versions.

2. Pass the Lisp string directly:

```
(sql:select [*] :from "TableNamewithVARIABLEcase")
```

Note that in this case the table name is passed to the database inside double quotes. That works only when the mode of the Common SQL connection contains `ANSI_QUOTES` (which is the default, see “SQL mode” on page 375 for details).

3. Specify table names as escaped symbols:

```
(sql:select [*] :from [|TableNamewithVARIABLEcase|])
```

4. Construct the whole query string and pass it to `query` rather than using `select`:

```
(sql:query "select * from TableNamewithVARIABLEcase")
```

### 23.9.3 Encoding (character sets in MySQL).

You can specify the encoding to be used by passing the `:encoding` argument to `connect`. Common SQL supports various encodings for MySQL as documented in `connect`, page 1533.

The default is to use the default for the particular MySQL installation.

### 23.9.4 SQL mode

Because Common SQL is geared towards ANSI SQL, by default it connects in ANSI mode. If another mode is required, it can be set at connection time.

For example, to make MySQL treat quotes as in ANSI without setting other ANSI features, do:

```
(sql:connect "me/mypassword/mydb"  
             :sql-mode "ANSI_QUOTES")
```

See the description of the `:sql-mode` argument to `connect`, page 1533 for details.

### 23.9.5 Meaning of the `:owner` argument to `select`

In the Common SQL MySQL interface, the value of the `select` keyword argument `:owner` is interpreted to select a database name.

### 23.9.6 Special considerations for iteration functions and macros

This section describes particular issues when fetching multiple records using Common SQL with MySQL databases.

#### 23.9.6.1 Fetching multiple records

The function `map-query` and the macros `do-query`, `simple-do-query` and `loop` with `each record` use internally `mysql-use-query`, which means that the underlying MySQL code brings the data from the server one record at a time. With a small number of records, it may be preferable to bring all the data immediately instead. This can be done by passing the argument `get-all`, as follows:

```
(sql:map-query nil 'print
  "select forname,surname from people"
  :get-all t)

(sql:do-query
  ((forname surname) "select forname,surname from people"
   :get-all t)
  body)

(sql:simple-do-query
  (list "select forname,surname from people"
    :get-all t)
  body)

(loop for (forname surname) being each record
  "select forname,surname from people"
  get-all t
  body)
```

### 23.9.6.2 Aborting queries which fetch many records

In the MySQL interface there is no way to abort a query when part way through it. When any of the iterations above stops before reaching its end, the underlying code retrieves all the records to the end of the query (though without converting them to Lisp objects). If the query found many records, that may be an expensive (that is, time consuming) operation.

It is possible to avoid this inefficiency by passing the argument *not-inside-transaction*. If *not-inside-transaction* is true then when a query is aborted, then LispWorks closes the database connection and reopens it, rather than retrieving all the remaining records.

```
(sql:map-query nil 'print
  "select forname,surname from people"
  :get-all t
  :not-inside-transaction t)
```

Note that this will lose any state associated with the connection, and so *not-inside-transaction* should only be used with care.

### 23.9.7 Table types

By default, `create-table` creates tables of the default type. This behavior can be overridden by the `connect` keyword arguments `:default-table-type`

## 23.9 Using MySQL

and `:default-table-extra-options`, and the `:type` and `:extra-options` keyword arguments to `create-table`.

If `type` is passed to `create-table` or `default-table-type` was passed to `connect`, it is used as the argument to the "keyword" `TYPE` in the SQL statement:

```
create table MyTable (column-specs) TYPE = type-value
```

If `extra-options` is passed to `create-table` or `default-table-extra-options` was passed to `connect`, it is appended in the end of the SQL statement above.

`connect` with `default-table-type` and `create-table` with `type` also accept the keyword argument `:support-transactions`. When `support-transactions` is true, these functions will attempt to make tables that support transactions. It does this by using the type `innodb`.

### 23.9.8 Rollback errors

The default value of the `connect` keyword argument `:signal-rollback-errors` is determined by the value of the `:default-table-type` argument. If `default-table-type` is `:support-transactions` or `"innodb"` or `"bdb"`, then the default value for `:signal-rollback-errors` is `t`, otherwise the default value is `nil`.

### 23.9.9 Types of values returned from queries

Common SQL uses the MySQL mechanism that returns values as strings.

By default, Common SQL converts these strings to the appropriate Lisp type corresponding to the column type (or more accurately, the type of the field in the query) according to Table 23.3

Table 23.3 MySQL type mapping

MySQL column type	Lisp Type	Meaning
All integer types	<code>integer</code>	
Double	<code>double-float</code>	
Single	<code>single-float</code>	

Table 23.3 MySQL type mapping

MySQL column type	Lisp Type	Meaning
Decimal	<code>rational</code>	
All String types	<code>string</code>	
All Binary types	<code>(array (unsigned-byte 8) *)</code>	
Date	<code>integer</code>	Universal time
Datetime	<code>integer</code>	Universal time
Timestamp	<code>integer</code>	Universal time
Time	<code>integer</code>	Number of seconds
Year	<code>integer</code>	Number of years

However, if you specify the result type as `:string`, this eliminates the conversion and the return value is simply the string retrieved by MySQL. For information about specifying the result type for a column (or multiple columns) in a query, see “Querying” on page 346.

Each of the five date-like types (that is, Date, Datetime, Timestamp, Time and Year) can have result type `:date`, `:date-string` or `:datetime-string` with the following effects:

`:date` This result type means a Universal time. This is the default except for Year.

`:date-string` A string with the format that MySQL uses for Date columns.

`:datetime-string` A string with the format that MySQL uses for Datetime columns.

### 23.10 Using Oracle

All the numeric types can have result type `:int`, `:single-float` or `:double-float`, causing the appropriate conversion. No check is made on whether the result is actually useful.

String types can have result type `:binary`, which returns an array.

#### 23.9.10 Autocommit

Common SQL sets `autocommit` to 0 when it opens a MySQL connection.

## 23.10 Using Oracle

This section describes particular issues in Common SQL with Oracle databases, apart from the LOB interface, which is described in “Oracle LOB interface” on page 380.

### 23.10.1 Connection specification

See “Connecting to Oracle” on page 338 for information about Oracle-specific interpretation of the `connection-spec` passed to `connect`.

### 23.10.2 Setting connection parameters

Oracle database connections have prefetch values which you can control via Common SQL. Alternatively you can allow the database default prefetch values to take effect.

You can set the default prefetch values for a connection by passing `:prefetch-rows-number` and `:prefetch-memory` keyword arguments to `connect`. The default value of `prefetch-rows-number` is 100 and the default value of `prefetch-memory` is #x100000 (meaning 1 MB of data).

You can also pass the value `:default` for either of these arguments. This means that Common SQL does not set the default. This is useful if Oracle itself provides a suitable default.

## 23.11 Oracle LOB interface

### 23.11.1 Introduction

The Common SQL Oracle LOB interface allows you to retrieve LOB locators and then perform operations on them. It is also possible to insert new empty LOBs.

#### 23.11.1.1 Retrieving LOB locators

This is done by normal `select` or `query` calls where the *selections* list names one or more columns that are of a LOB type. The LOB types are BLOB, CLOB, NCLOB, BFILE and CFILE.

The returned value is a LOB locator: an opaque Lisp object on which the `ora-lob-*` APIs (that is, those functions with names beginning with "ora-lob-") can be used. This LOB locator contains a pointer to an Oracle descriptor of type OCILobLocator\*. Note that there can be multiple LOB locator objects associated with the same LOB in the server, but a LOB locator uniquely identifies a LOB object.

It is possible to specify that the result object should be a stream either for input or output. Then the resulting stream (which will be of type `lob-stream`) can be used as a normal Lisp stream.

#### 23.11.1.2 Operating on LOB locators

This is done using the `ora-lob-*` functions. Most of these functions map directly to the underlying OCILob\* functions.

Note that when modifying a LOB locator, the corresponding record must be locked. See “Retrieving Lob Locators” on page 381 for details.

#### 23.11.1.3 Inserting empty LOBs

To add a new LOB object to the database, you must insert an empty LOB. The preferred way of doing this is to use the Oracle SQL functions EMPTY\_BLOB and EMPTY\_CLOB, which can be called by using the pseudo operator `sql-function`, like this:

### 23.11 Oracle LOB interface

```
(sql:insert-records :into [mytable]
    :values
        (list "name" [sql-function 'empty_blob]))
```

This code inserts a record with "name" and an empty BLOB. It is also possible to make an empty LOB by calling `ora-lob-create-empty`, and passing the empty LOB as a value to `insert-records` or `update-records`.

#### 23.11.2 Retrieving Lob Locators

When the selections list of a query that is used in `select`, `query`, `do-query`, `map-query`, `simple-do-query` or `loop .... for x being each record` contains a column of a LOB type, the results are LOB locator objects. For example, if the table definition is:

```
create table mytable {
    name varchar(200),
    image blob
}
```

Then doing

```
(sql:select [image] :from [mytable] :flatp t)
```

returns a list of LOB locators.

This example lists the size of the images in the table mytable:

```
(dolist (pair (sql:select [name] [image] :from [mytable]))
    (format t "~a has an image of size ~a~%" 
            (first pair) (sql:ora-lob-get-length (second pair)))
    (sql:ora-lob-free (second pair)))
```

or more efficiently

```
(sql:do-query ((name lob-locator)
                [sql:select [name] [image] :from [mytable]])
                (format t "~a has an image of size ~a~%" 
                        name (sql:ora-lob-get-length lob-locator)))
```

**Note:** The lifetime of the LOB locator objects differs between the functions that return a list of objects (`select` and `query`) and the iterative functions and macros (`do-query`, `simple-do-query`, `loop` and `map-query`). The iteration functions and macros free the LOB locators that they retrieve before proceeding to the next iteration. `select` and `query` do not free the LOB locators. Each

LOB locator stays alive until the application makes an explicit call to `ora-lob-free`, or until the database is closed by a call to `disconnect`.

### 23.11.3 Locking

When the LOB or its contents need to modified, the corresponding record must be locked (Oracle enforces this). The best way to lock a record is to pass `:for-update` when calling `select`. See `select`, page 1634 for details. For example, writing a line in the end of the log file of station number 573:

```
create table logfiles (stationid integer, logfiles clob)
    .. insert records ..

(sql:do-query ((log-stream)
    [select [log :output-stream] :from [logfiles]
     :where [= [stationid] 573] :for-update t])
    (file-position log-stream :end)
    (write-line "Add this line to the log" log-stream)
    (close log-stream) ; forces the output
  )
(sql:commit)
```

Note that any call to `commit` or `rollback` on the same connection removes the lock. If you want to modify the LOB later, you must lock it again. An efficient way to achieve this is to use the special token `ROWID`, which returns the `ROWID` in the database, because this does not involve searching on the server side. For example:

### 23.11 Oracle LOB interface

```
(let ((lobs-list
      (sql:select [lob-field] [rowid] ; get pairs of LOB
                  :from [mytable] ; locators and ROWIDs
                  :where [some-condition])))
    ... do something ...
    ... reach a point when we want to modify one
    ... of the LOBS above and have bound one of the
    ... pairs in the variable pair.
    (sql:select [1]
                :from [mytable] ; retrieve a constant
                :where
                  [= [rowid] (second pair)] ; get the right record
                  :for-update t) ; lock it
    (sql:ora-lob-write-buffer (car pair) ; modify the lob
                               offset
                               amount
                               buffer)
    (sql:commit) ; also unlock everything
  )
```

#### 23.11.4 Retrieving LOB Locators as streams

To retrieve LOB locators as streams, specify the type of retrieved object as `:input-stream` or `:output-stream` in the query. For example:

```
(sql:select [image :input-stream] :from [mytable] :flatp t)
```

returns a list of streams.

For example, to print the name of all images that start with some "magic number", that is a sequence of 4 specific bytes (#xf5 #x12 #x4e #x23):

```
(let ((array (make-array 4 :element-type '(unsigned-byte 8))))
  (sql:do-query ((name lob-stream)
                 [sql:select [name] [image :input-stream]
                           :from [mytable]])
    (when (and (read-sequence array lob-stream) 4)
      (eq (aref array 0) #xf5)
      (eq (aref array 0) #x12)
      (eq (aref array 0) #x4e)
      (eq (aref array 0) #x23))
      (print name))))
```

Closing the stream also frees the LOB object.

When using `:output-stream`, it is important to call `force-output` before trying to commit the changes, because the stream is buffered.

### 23.11.5 Attaching a stream to a LOB locator

It is possible to attach a stream to a LOB locator, passing the LOB locator as a `:lob-locator` argument to `(make-instance 'lob-stream ...)`. The value of the `:direction` argument must be `:input` or `:output`. By default, if the stream is closed the LOB locator is freed, unless the value of the initarg `:free-lob-locator-on-close` is passed as `nil`.

Operations via the stream can be mixed with direct operations on the LOB. However, because of the buffering, accessing the LOB contents will give non-obvious results, as other operations may not see something that was written to the stream because it is still in the stream buffer, or the stream may have already read some contents before they were overwritten. Use `force-output` or `clear-input` before accessing the LOB in other ways to avoid these problems.

It is possible to attach more than one stream to the same LOB locator, in both directions. Apart from the issue of the buffering described above, the streams can be used independently of each other. Note that if you want to close one of the streams and to continue to use the others or the LOB locator itself, you must pass `:free-lob-locator-on-close nil` when you make the stream.

The LOB locator to which a stream is attached can be found by using the reader `lob-stream-lob-locator`.

### 23.11.6 Interactions with foreign calls

You can define your own foreign calls and use them on the underlying OCI descriptors. For this, you need to access the OCI handles using `ora-lob-lob-locator`, and maybe `ora-lob-env-handle` and `ora-lob-svc-ctx-handle`. These accessors return foreign pointers that can be passed to foreign functions in the usual way.

When the foreign functions deal only with the data, rather than with LOB objects, use the functions `ora-lob-read-foreign-buffer`, `ora-lob-write-foreign-buffer` and `ora-lob-get-buffer`.

For example:

### 23.11 Oracle LOB interface

```
;;; You have a C function my_lob_processor
;;; int my_lob_processor(OCILobLocator *lob,
;;;                      OCISvcCtx *Context,
;;;                      int other_arg)

(fli:define-foreign-function my-lob-processor
  ((lob sql:p-oci-lob-locator)
   (env sql:p-oci-svc-ctx)
   (other-arg :int))
  :result-type :int)
```

Assuming you have the LOB locator in the variable *lob*, call the foreign function on it:

```
(my-lob-processor (sql:ora-lob-lob lob)
                  (sql:ora-lob-svc-ctx-handle lob)
                  36)
```

There are three handles in the LOB: the LOB descriptor itself, the environment and the context. The pointer types, the reader and the corresponding C type for each handle are shown in Table 23.4 below.

Table 23.4 Handles in the LOB locator

OCI handle	Reader	Pointer type	C type
LOB descriptor	ora-lob-lob-locator	p-oci-lob-locator or p-oci-file	OCILobLocator*
context	ora-lob-svc-ctx-handle	p-oci-svc-ctx	OCISvcCtx*
environment	ora-lob-env-handle	p-oci-env	OCIEnv*

The pointer type **p-oci-lob-locator** is used for internal LOBs (that is, BLOB, CLOB and NCLOB). The pointer type **p-oci-file** is used for file LOBs (CFILE and BFILE). For functions that take both, the type **p-oci-lob-or-file** is defined as the union of these two types

### 23.11.7 Determining the type of a LOB

The function `ora-lob-internal-lob-p` returns whether it is internal (that is BLOB, CLOB or NCLOB) or not (that is BFILE or CFILE). The function `ora-lob-element-type` returns the LISP element type that best corresponds to the LOB locator. This will be one of (`unsigned-byte 8`) for BLOB and BFILE, or `base-char` or `bmp-char` for CLOB, NCLOB and CFILE, depending on the charset of the LOB object.

It is possible to distinguish between CLOB and NCLOB by looking at the result of `ora-lob-char-set-form`. It returns 2 for NCLOB and 1 for CLOB.

### 23.11.8 Reading and writing from and to LOBs

One way of reading and writing is to use streams as described in the section “Retrieving LOB Locators as streams” on page 383. When large amounts of data are written (read) to (from) the LOB the direct interface may be useful. The direct interface is implemented by `ora-lob-read-foreign-buffer`, `ora-lob-read-buffer`, `ora-lob-write-foreign-buffer`, and `ora-lob-write-buffer`.

All the direct interfaces are more efficient if the buffer that is passed is static. That is always true for the `*-foreign-buffer` functions, but normally not true for Lisp objects. See the documentation for `make-array`, page 680. See also `ora-lob-get-buffer`.

The direct reading and writing methods can be used for "random" access, but they can also be used conveniently for efficient linear access, simply by passing `nil` as the `offset` parameter.

### 23.11.9 The LOB functions

Most of the LOB functions take an `errorp` argument, which is a boolean controlling what happens if an error occurs inside an OCI function. If `errorp` is true, an error is signaled. If `errorp` is false, the function returns an error object (of type `sql-database-error`).

All the LOB functions signal an error if the `lob-locator` argument given is not a LOB locator object as returned by `select` or `query`.

## 23.11 Oracle LOB interface

Many of the functions basically perform a call to the underlying OCI function. When the match is direct, this is mentioned in the function's manual page.

### 23.11.9.1 Querying functions

You can test whether a LOB locator is initialized, open or temporary with `ora-lob-locator-is-init`, `ora-lob-is-open` or `ora-lob-is-temporary`.

The predicate for internal LOBs is `ora-lob-internal-lob-p`.

`ora-lob-element-type` returns a Lisp element type corresponding to the LOB locator as described "Determining the type of a LOB" on page 386.

`ora-lob-lob-locator`, `ora-lob-env-handle` and `ora-lob-svc-ctx-handle` return foreign pointers to the various handles in the LOB mentioned in "Interactions with foreign calls" on page 384. To determine the best value for the size of a buffer use `ora-lob-get-chunk-size`.

`ora-lob-char-set-form` and `ora-lob-char-set-id` query the charset of a *lob-locator*.

The querying functions specifically for file LOBs are `ora-lob-file-exists`, `ora-lob-file-is-open` and `ora-lob-file-get-name`

You can obtain the current length of the LOB with `ora-lob-get-length`.

You can test two LOB locators for whether they point to the same LOB object with `ora-lob-is-equal`.

### 23.11.9.2 LOB management functions

You can create a LOB object with `ora-lob-create-empty`.

You can assign a LOB to another LOB locator with `ora-lob-assign`.

You can free a LOB locator with `ora-lob-free`.

### 23.11.9.3 Modifying LOBs

All the functions mentioned in this section are applicable to internal LOBs only, except `ora-lob-load-from-file`.

Before modifying a LOB, the corresponding record must be locked. See the discussion in “Locking” on page 382.

If you make several modifications to a LOB which has functional or domain indexes, it is useful to wrap several calls of modifying functions in a pair of `ora-lob-open` and `ora-lob-close`. That means that the indexes will be updated once (when `ora-lob-close` is called), which saves work. Note that after a call to `ora-lob-open`, `ora-lob-close` must be called before any call to `commit`.

To append the contents of one LOB to another, use `ora-lob-append`.

You can copy all or part of a LOB into another LOB using `ora-lob-copy`.

`ora-lob-load-from-file` loads the data from a file LOB into an (internal) LOB.

You can erase (that is, fill with the 0 byte or with Space character) all or part of a LOB using `ora-lob-erase`.

You can reduce the size of a LOB using `ora-lob-trim`.

If you need to make multiple updates to a LOB you can optionally create a transaction using `ora-lob-open` and `ora-lob-close` call. This may save work on the server side.

#### 23.11.9.4 File operations

These functions are used to modify the properties of file LOBs.

Open and close the file associated with a file LOB using `ora-lob-file-open` and `ora-lob-file-close`.

You can close all the files associated with a file LOB locator that have been opened through the database connection with `ora-lob-file-close-all`.

You can alter the directory and/or the file name for a file LOB locator by calling `ora-lob-file-set-name`.

#### 23.11.9.5 Direct I/O

The direct I/O functions perform input or output directly on the OCI handle, without the intervening layer of a stream. If you move large amounts of data

### 23.11 Oracle LOB interface

to or from the LOB, and in particular if you pass the data to or from foreign functions, the direct calls can be more efficient, and in some cases also more convenient to use. Note, however, that if you make many small modifications to the data, the `lob-stream` interface may be more efficient.

Note also that the difference in efficiency between the direct calls and the `lob-stream` interface is likely to be quite small compared to the time spent on network traffic.

If you make many modifications to a LOB, you should also consider wrapping the operations in a transaction created by a pair of calls to `ora-lob-open` and `ora-lob-close`.

You can read data from the LOB locator into a Lisp buffer or foreign buffer using `ora-lob-read-buffer` and `ora-lob-read-foreign-buffer` respectively.

Similarly `ora-lob-write-buffer` and `ora-lob-write-foreign-buffer` can be used to write buffer to a LOB.

You can obtain a buffer suitable for efficient I/O with foreign functions via `ora-lob-get-buffer`.

`ora-lob-read-into-plain-file` writes the contents of a LOB into a file.

`ora-lob-write-from-plain-file` writes the contents of a file into a LOB.

#### 23.11.6 Temporary LOBs

You can create a temporary LOB with `ora-lob-create-temporary`.

You can test whether a LOB is temporary with `ora-lob-is-temporary`.

You can free a temporary LOB locator if necessary with `ora-lob-free-temporary`, though temporary LOB locators are freed automatically when the database connection is closed by `disconnect`.

#### 23.11.7 Control of buffering

These functions control the internal buffering by the Oracle client: `ora-lob-enable-buffering`, `ora-lob-disable-buffering`, and `ora-lob-flush-buffer`. They have no interaction with any of the other functions above.

### 23.11.10 Fetching the contents of the LOBs directly

Sometimes it is useful to fetch the contents of a LOB directly. You can do that by specifying the type of the requested value as `:binary` for binary LOBs (BLOB and BFILE) or `:string` for character LOBs (CLOB, NCLOB, and CFILE). When you specify the type in this way, the fetched values are arrays of type `(unsigned-byte 8)` for `:binary` and strings for `:string`. For example:

```
(sql:select [blob_column] :from [a_table])
=>
a list of LOB locators

(sql:select [blob_column :binary] :from [a_table])
=>
a list of arrays
```

## 23.12 Using ODBC

### 23.12.1 Configuring unixODBC

On Unix, configure unixODBC in these files.

For the driver:

```
/etc/odbcinst.ini
```

For the datasource:

```
~/.odbc.ini
```

```
/etc/odbc.ini
```

### 23.12.2 Loading unixODBC

At load time do:

```
(require "odbc")
```

At run time on Unix, Common SQL automatically loads the unixODBC module from the location in the variable `sql::*odbc-foreign-modules*`. In LispWorks for Linux this variable initially has the value `("~/usr/lib/libodbc.so")`. Therefore if, for example, the run time machine unixODBC

## 23.12 Using ODBC

installed in

/usr/local/, at run time do:

```
(setq sql::*odbc-foreign-modules* '("/usr/local/lib/libodbc.so"))
(sql:connect "mydatabase" :database-type :odbc)
```

### 23.12.3 External format for ODBC strings

On Unix, the default external format for ODBC strings is :ascii. On Microsoft Windows it is win32:\*multibyte-code-ef\*.

### 23.12.4 Using non-ASCII strings on Microsoft SQL Server

When passing a SQL expression containing string literals to Microsoft SQL Server (which you can do via ODBC), if a string literal contains characters that the server's code page cannot represent, then the string literal needs to be marked as "Native" by prefixing it with the character 'N' before the opening quote. For example:

```
N'Greek'
```

Code pages always can always represent ASCII characters, but differ in what other characters can represent. The functions `string-needs-n-prefix` and `string-prefix-with-n-if-needed` are provided to check if a string needs prefixing.

Other SQL backends work with all strings regardless of the N syntax, but the syntax is allowed by most of them as well (and is standard SQL). However, SQLite and Microsoft Access (via ODBC) do not recognize the N syntax, and give an error. This means that static SQL expressions, which are generated before knowing which SQL backend is going to be used, cannot reliably use the N syntax. In addition, knowing exactly which strings need the N syntax requires knowledge of the code page in the server, and hence requires the database to be opened already when `string-needs-n-prefix` or `string-prefix-with-n-if-needed` are called.

The syntax described in “Symbolic SQL syntax” on page 358 generates static expressions when possible, and Lisp string values within them are processed independently of any database to produce string literals without the N syntax. This can be overridden by using the `string` pseudo-operator, which is described in “SQL string literals” on page 366, and can decide dynamically

whether to use the N syntax or not. Thus you should use the `string` pseudo-operator in any symbolic SQL syntax that may be used with Microsoft SQL Server and contains SQL string literals (including Lisp expressions that evaluate to strings) to ensure that it works on Microsoft SQL Server for all strings and is also portable.

If you want to work with Microsoft SQL Server and do not require portability to SQLite or Microsoft Access, then you can set `*use-n-syntax-for-non-ascii-strings*` to `t` to always use the N syntax. However, the N prefix changes the type of the string inside Microsoft SQL Server to "Unicode", which has a different collation to non-Unicode strings, so if you need the non-Unicode collation for strings that have codes in the server's code page then this may not be the right approach.

Another approach is to use `prepare-statement` with a bind-variable for the string, which works on all SQL backends without any additional code (because the string is not used as a literal in the SQL expression):

```
(setq *a-prepared-statement*
      (sql:prepare-statement [sql:select [name]
                             :from [sometable]
                             :where [= [nchar_column] [1]]]))
...
(sql:set-prepared-statement-variables *a-prepared-statement*
                                      (list a-non-ascii-string))
(sql:query *a-prepared-statement*)
```

The functions `update-records` and `insert-records` also do not use the values that they get as literals in SQL expressions when modifying a Microsoft SQL Server database, and therefore do not require additional code for the values. However, the `where` expression in `update-records` and the `query` expression in `insert-records` are used directly, so if they contain non-ASCII strings as literals then they will need to be modified for Microsoft SQL Server.

## 23.13 Using SQLite

This section describes particular issues in Common SQL with SQLite databases.

### 23.13.1 Connecting to SQLite

See “Connecting to SQLite.” on page 343 for information about SQLite-specific *connection-spec* and *sqlite-keywords* arguments to `connect`.

### 23.13.2 Types of retrieved fields in queries

By default, when doing queries (`select`, `query`, `map-query`, `do-query`, `simple-do-query`, `loop` with `each record` and `print-query`) the LispWorks checks the data type of each field it reads in each row, and fetches the data accordingly (using the C functions `sqlite3_column_*` like `sqlite3_column_int` in the SQLite3 library). Values of SQLite data types `NULL`, `INTEGER`, `REAL` and `TEXT` are mapped to Lisp objects of type `null`, `integer`, `double-float` and `string` respectively ("mapped" means returned from `select` or `query`, printed in `print-query`, or passed to your code in the other APIs). A value of data type `BLOB` is mapped to an array with element type `(unsigned-byte 8)` containing all of the bytes of the `BLOB`.

You can force the value to a specific type by specifying the type explicitly. This is done by specifying the type with the identifier, either using the symbolic SQL syntax (see “Enclosing database identifiers” on page 359) or using `sql-expression`. For `select` and `query` you can also use the keyword argument `:result-types`.

The types that LispWorks recognizes for SQLite are the common types: `:integer` (alias `:int`), `:string`, `:double-float` and `:binary`. These match the SQLite data types `INTEGER`, `TEXT`, `REAL` and `BLOB` respectively. When these keywords are used, LispWorks asks SQLite for a value of the corresponding data type, and converts it to the matching Lisp object type as above. Note that the value can also be `nil`, if the the value is `null` or cannot be converted to the requested Lisp object type.

Other possible values for the type are:

`:single-float`

LispWorks asks SQLite for a `REAL`, and coerces it to a `single-float`.

<code>nil</code>	Use the default behavior. Useful if you use <code>:result-types</code> and want to force the type of some of the fields but not all of them.
<code>:blob</code>	Returns a handle to the raw data of a BLOB, from which you can read the data using the APIs described in “Reading from blobs using a handle (sqlite-raw-blob) and modifying blobs (sqlite-blob)” on page 394. This allows more flexible access to BLOB values.  <code>:blob</code> cannot be used with <code>select</code> or <code>query</code> .

Note that SQLite does not support any kind of date data type.

When the value that is stored in the database does not match the value that it is asked for, the SQLite library converts the value to the required type, so you always get a value of the correct type, but not necessarily a useful value. See the documentation for SQLite for details: [https://www.sqlite.org/c3ref/column\\_blob.html](https://www.sqlite.org/c3ref/column_blob.html) "Result Values From a Query".

### 23.13.3 Tables containing a uniform type per column

SQLite allows the fields in each row to contain any supported type, rather than being constrained to the type specified for the column in the table definition.

When you connect to a database, you can use the SQLite-specific keyword `:uniform-type-per-column` in *sqlite-keywords* with value `t` to tell LispWorks that all of the values of a column returned by a query have the same data type.

When you do that, for fields where you do not specify the type explicitly, the LispWorks checks the type of the field in the first result row, and then uses it for the rest of the rows.

### 23.13.4 Reading from blobs using a handle (sqlite-raw-blob) and modifying blobs (sqlite-blob)

When the type of a field in a query is specified as `:blob`, the SQLite BLOB is mapped to an object of type `sqlite-raw-blob`. You can then read data from the SQLite BLOB using any the functions `copy-from-sqlite-raw-blob`,

### 23.13 Using SQLite

`replace-from-sqlite-raw-blob` or `sqlite-raw-blob-ref`. The function `sqlite-raw-blob-length` can be used to find the size of the BLOB (in bytes).

The `sqlite-raw-blob` is valid only within the dynamic extent of the function that is called from the Common SQL interface. If you try to read from a `sqlite-raw-blob` outside this dynamic context, an error of type `sql-user-error` will be signaled. You can use `sqlite-raw-blob-valid-p` to check if a blob is valid.

Using `sqlite-raw-blob` makes it more convenient to read the data when a BLOB contains elements larger than bytes, and makes it more efficient when you retrieve large BLOBs (a few kilobytes or more) but need only a small part of the data.

SQLite allows reading and writing of BLOBS (fields with type BLOB or TEXT) directly, which you can do using the `sqlite-blob` interface. The functions `sqlite-open-blob` and `sqlite-close-blob` are used to open and close a BLOB field, or the macro `with-sqlite-blob` can be used to do both. Once you have opened a BLOB, you call `replace-from-sqlite-blob` or `replace-into-sqlite-blob` to copy data to or from it. Note that the `sqlite-blob` is not thread-safe, so you must do all of the operations in a "single thread" context (either all in one thread, or serialized by a lock).

`sqlite-raw-blob` corresponds to the result of the C function `sqlite3_column_blob` (and `sqlite3_column_bytes` to obtain the size).  
`sqlite-blob` corresponds to the C structure `sqlite3_blob`.

#### 23.13.5 Values in Insert and Update.

When modifying a table in SQLite, either directly by using `insert-records` or `update-records`, or by executing a `prepared-statement` statement with bind-variables, the values that are passed are treated as follows:

In a `prepared-statement`, if the variable-type is `:string`, then the value is converted to a string.

The value is passed to the SQLite library as a SQLite data type based on the type of the value as follows:

```
(signed-byte 64)  
INTEGER
```

<code>float</code>	REAL
<code>string</code>	TEXT
<code>null</code>	NULL
Binary array	BLOB
<code>list</code>	See below

A binary array is an array with an integer or float element type. `bmp-string` and `base-string` are also binary arrays in some contexts, but they are treated as strings in this case (`text-string` is not a binary array).

In addition, the value can be a list, which is treated as follows:

- If the first element of the list is a binary array, including `bmp-string` or `base-string`, then the list must be of form `(array)`, `(array start)` or `(array start end)` and the bytes between `start` and `end` in `array` are inserted as a BLOB. If `start` is omitted, it defaults to 0. If `end` is omitted, it defaults to the length of `array`.

Note that `start` and `end` are denoted in elements rather than bytes, so the number of the bytes in the BLOB is  $(\star (- \text{end} \text{start}) \text{bytes-per-element})$ . Note also that, for arrays of more than one byte per element, the contents of the BLOB will depend on the byte order of the host machine.

Apart from allowing insertion of parts of arrays, this syntax also allows you to insert the character codes in a `bmp-string` and `base-string` as a BLOB, by passing the string as a list of one element.

- If the first element of the list is the keyword `:zeroblob`, then the second element is treated as a size, which must be a positive integer smaller than  $2^{31}$ , that is of type `(integer 0 #xfffffff)`. LispWorks inserts a zero blob of this size (using the C function `sqlite3_bind_zeroblob`).

Any value that does not match the description above, including integers out of range and lists that do not match the patterns described, cause an error (of type `sql-user-error`) to be signaled.

### 23.13.6 Accessing ATTACHED databases

ATTACHED databases in SQLite, that is databases that were attached using the SQLite ATTACH statement, are identified by their schema names. You can

### 23.13 Using SQLite

specify the schema name in the "[...]" syntax, for example, if you attach a file called "another-database" as follows:

```
(execute-command "ATTACH another-database as AttachedDB")
```

then you can read the contents of a table SomeTable inside "another-database" using AttachedDB as the "schema" name:

```
(select [*] :from [AttachedDB SomeTable])
```

The keyword **:owner** in Common SQL function specifies the schema to which the table(s) belong, for example, after the ATTACH above, you can obtain the list of tables inside another-database by using:

```
(sql:list-tables :owner "AttachedDB")
```

and use AttachedDB as the "owner" in **sql-expression**:

```
(select [*] :from (sql-expression :owner "AttachedDB"
                     :table "SomeTable"))
```

See [https://www.sqlite.org/lang\\_attach.html](https://www.sqlite.org/lang_attach.html) "ATTACH DATABASE" for details about attaching in SQLite.

# 24

---

# User Defined Streams

## 24.1 Introduction

A number of classes and functions are provided in the `stream` package that allow you to define your own input and output streams. You can use the standard Common Lisp I/O functions on these streams, and you can add methods specialized on your stream classes to provide specific implementations of other I/O functions. Note that some changes have been made to the standard I/O functions to allow for this. For example, `stream-element-type` is now a generic function. See Chapter 33, “The COMMON-LISP Package” for alterations to Common Lisp functions, and Chapter 48, “The STREAM Package” for more details on the API for user defined streams.

## 24.2 An illustrative example of user defined streams

In this chapter an example is provided to illustrate the main features of the `stream` package. In this example a stream class is defined to provide a wrapper for `file-stream` which uses the Unicode Line Separator instead of the usual ASCII CR/LF combination to mark the end of lines in the file. Methods are then defined, specializing on the user defined stream class to ensure that it handles reading from and writing to a file correctly.

### 24.2.1 Defining a new stream class

Streams can be capable of input or output (or both), and may deal with characters or with binary elements. The `stream` package provides a number of stream classes with different capabilities from which user defined streams can inherit. In our example the stream must be capable of input and output, and must read characters. The following code defines our stream class appropriately:

```
(defclass unicode-ls-stream
  (stream:fundamental-character-input-stream
   stream:fundamental-character-output-stream)
  ((file-stream :initform nil
                :initarg :file-stream
                :accessor ls-stream-file-stream)))
```

The new class, `unicode-ls-stream`, has `fundamental-character-input-stream` and `fundamental-character-output-stream` as its superclasses, which means it inherits the relevant default character I/O methods. We shall be overriding some of these with more relevant and efficient implementations later.

Note that we have also provided a `file-stream` slot. When making an instance of `unicode-ls-stream` we can create an instance of a Common Lisp file stream in this slot. This allows us to use the Common Lisp file stream functionality for reading from and writing to a file.

### 24.2.2 Recognizing the stream element type

We know that the stream will read from a file using `file-stream` functionality and that the stream element type will be `character`. The following defines a method on `stream-element-type` to return the correct element type.

```
(defmethod stream-element-type ((stream unicode-ls-stream))
  'character)
```

### 24.2.3 Stream directionality

Streams can be defined for input only, output only, or both. In our example, the `unicode-ls-stream` class needs to be able to read from a file and write to a file, and we therefore defined it to inherit from an input and an output stream class. We could have defined disjoint classes instead, one inheriting

from `fundamental-character-input-stream` and the other from `fundamental-character-output-stream`. This would have allowed us to rely on the default methods for the direction predicates.

However, given that we have defined one bi-directional stream class, we must define our own methods for the direction predicates. To allow this, the Common Lisp predicates `input-stream-p` and `output-stream-p` are implemented as generic functions.

```
(defmethod input-stream-p ((stream unicode-ls-stream))
  (input-stream-p (ls-stream-file-stream stream)))

(defmethod output-stream-p ((stream unicode-ls-stream))
  (output-stream-p (ls-stream-file-stream stream)))
```

The above code allows us to “trampoline” the correct direction predicate functionality from `file-stream`, using the `ls-stream-file-stream` accessor we defined previously.

#### 24.2.4 Stream input

The following method for `stream-read-char` reads a character from the stream. If the character read is a `#\Line-Separator`, then the method returns `#\Newline`, otherwise the character read is returned. `stream-read-char` returns `:eof` at the end of the file.

```
(defmethod stream:stream-read-char ((stream unicode-ls-stream))
  (let ((char (read-char (ls-stream-file-stream stream)
                        nil :eof)))
    (if (eql char #\Line-Separator)
        #\Newline
        char)))
```

There is no need to define a new method for `stream-read-line` as the default method uses `stream-read-char` repeatedly to read a line, and our implementation of `stream-read-char` ensures that this will work.

We also need to make sure that if a `#\Newline` is unread, it is unread as a `#\Line-Separator`. The following method for `stream-unread-char` uses the Common Lisp file stream function `unread-char` to achieve this.

```
(defmethod stream:stream-unread-char ((stream unicode-ls-stream)
                                       char)
  (unread-char (if (eql char #\Newline) #\Line-Separator char)
               (ls-stream-file-stream stream)))
```

Finally, although the default methods for `stream-listen` and `stream-clear-input` would work for our stream, it is faster to use the functions provided by `file-stream`, again using our accessor `ls-stream-file-stream`.

```
(defmethod stream:stream-listen ((stream unicode-ls-stream))
  (listen (ls-stream-file-stream stream)))

(defmethod stream:stream-clear-input ((stream unicode-ls-stream))
  (clear-input (ls-stream-file-stream stream)))
```

### 24.2.5 Stream output

The following method for `stream-write-char` uses `write-char` to write a character to the stream. If the character written to `unicode-ls-stream` is a `#\Newline`, then the method writes a `#\Line-Separator` to the file stream.

```
(defmethod stream:stream-write-char ((stream unicode-ls-stream)
                                       char)
  (write-char (if (eql char #\Newline)
                 #\Line-Separator
                 char)
              (ls-stream-file-stream stream)))
```

The default method for `stream-write-string` calls `stream-write-char` repeatedly to write a string to the stream. However, the following is a more efficient implementation for our stream.

```
(defmethod stream:stream-write-string ((stream unicode-ls-stream)
                                         string &optional (start 0)
                                         (end (length string)))
  (loop with i = start
        until (>= i end)
        do (let* ((newline (position #\Newline
                                      string :start i :end end))
                  (this-end (or newline end)))
            (write-string string (ls-stream-file-stream stream)
                         :start i :end this-end)
            (incf i this-end)
            (when newline
              (stream:stream-terpri stream)
              (incf i)))
        finally (return string)))
```

We do not need to define our own method for `stream-terpri`, as the default uses `stream-write-char`, and therefore works appropriately

To be useful, the `stream-line-column` and `stream-start-line-p` generic functions need to know the number of characters preceding a `#\Line-Separator`. However, since the LispWorks file stream records line position only by `\Newline` characters, this information is not available. Hence we define the two generic functions to return `nil`:

```
(defmethod stream:stream-line-column
  ((stream unicode-ls-stream))
  nil)

(defmethod stream:stream-start-line-p
  ((stream unicode-ls-stream))
  nil)
```

Finally, the methods for `stream-force-output`, `stream-finish-output` and `stream-clear-output` are “trampolined” from the standard `force-output`, `finish-output` and `clear-output` functions.

```
(defmethod stream:stream-force-output ((stream
                                         unicode-ls-stream))
  (force-output (ls-stream-file-stream stream)))

(defmethod stream:stream-finish-output ((stream
                                         unicode-ls-stream))
  (finish-output (ls-stream-file-stream stream)))
```

```
(defmethod stream:stream-clear-output ((stream
                                         unicode-ls-stream))
  (clear-output (ls-stream-file-stream stream)))
```

### 24.2.6 Instantiating the stream

Now that the stream class has been defined, and all the methods relevant to it have been set up, we can create an instance of our user defined stream to test it. The following function takes a filename and optionally a stream direction as its arguments and makes an instance of `unicode-ls-stream`. It ensures that the `file-stream` slot of the stream contains a Common Lisp `file-stream` capable of reading from or writing to a file given by the filename argument.

```
(defun open-unicode-ls-file (filename &key (direction :input))
  (make-instance 'unicode-ls-stream :file-stream
    (open filename
      :direction direction
      :external-format :unicode
      :element-type 'character)))
```

The following macro uses `open-unicode-ls-stream` in a similar manner to the Common Lisp macro `with-open-file`:

```
(defmacro with-open-unicode-ls-file ((var filename
                                         &key (direction :input))
                                         &body body)
  `(let (,(var (open-unicode-ls-file ,filename
                                         :direction ,direction)))
    (unwind-protect
      (progn ,@body)
      (close ,var))))
```

We now have the required functions and macros to test our user defined stream. The following code uses `config.sys` as a source of input to an instance of our stream, and outputs it to the file `unicode-ls.out`, changing all occurrences of `#\Newline` to `#\Line-Separator` in the process.

```
(with-open-unicode-ls-file (ss "C:\\unicode-ls.out"
                               :direction :output)
  (write-line "-- Encoding: Unicode; --" ss)
  (with-open-file (ii "C:\\config.sys") ; Don't edit this file!
    (loop with line = nil
          while (setf line (read-line ii nil nil))
          do (write-line line ss))))
```

After running the above code, if you load the file `C:\\unicode-ls.out` into an editor (for example, a LispWorks editor), you can see the line separator used instead of CR/LF. Most editors do not yet recognize the Unicode Line Separator character yet. In some editors it appears as a blank glyph, whereas in the LispWorks editor it appears as `<2028>`. In LispWorks you can use `Alt+X What Cursor Position` or `Ctrl+X =` to identify the unprintable characters.

You can also use the follow code to print out the contents of the new file line by line.

```
(with-open-unicode-ls-file (ss "C:\\unicode-ls.out")
  (loop while (when-let (line (read-line ss nil nil))
            (write-line line))))
```

# 25

---

# TCP and UDP socket communication and SSL

The interface for using sockets in LispWorks is in the "comm" module, and all the symbols are in the `comm` package, and documented in the "The COMM Package" on page 513.

To use it you need to require the module by

```
(require "comm")
```

## 25.1 Running a server that accepts connections

The function `start-up-server` starts a new thread which:

1. Creates a socket, then
2. Prepares it (that is, binds it to the address and port and does various other settings) and then
3. Waits for connections to it ("accepting connections")

When a connection is made, a programmer-supplied function is called with the new socket. Typically this function creates a stream of type `socket-stream` with this socket, and then uses the stream for communication through the socket using standard Common Lisp I/O functions.

## 25.2 Connecting to a server

The function `open-tcp-stream` connects to a server and returns a stream (of type `socket-stream`). The stream is then used for communication through the socket using the standard Lisp I/O functions.

`connect-to-tcp-server` can also be used, especially if you want to subclass `socket-stream`.

### 25.2.1 Examples

For examples illustrating simple write and read on a socket, see these files in `lib/7-1-0-0/examples`

```
capi/applications/chat.lisp
capi/applications/chat-client.lisp
```

## 25.3 Specifying the target for connecting and binding a socket

In general, each socket is bound to a local socket address, and is communicating with some other socket which has its own socket address. The local binding may be done implicitly by the system, but in many cases (in general, when it is a service) it needs to be bound to specific socket address. When connecting to another socket, or sending using UDP socket, the socket address of the other side is needed.

The socket address is always specified by a *hostspec* and *service*. *hostspec* is also referred to as "address" or "hostname" or "host", and the *service* is sometimes referred to as "port". In particular, the local *hostspec* and local *service* are called *local-address* and *local-port*.

*hostspec* specifies an IP address. It can be one of:

A string naming the host, for example "www.google.com".

Such a string is looked up by the system to find the actual IP address.

A string providing the IP address in standard format.

Example: "204.71.177.5" (IPv4)

Example: "2001:500:2f::f" (IPv6).

An integer specifying IPv4 address in network order.

Example: #xcc47B14B.

An `ipv6-address` object.

The functions `string-ip-address` and `ip-address-string` convert between strings that specify addresses and integers or `ipv6-address` objects. If you need to find the actual address from a string giving the host name, you need to look it up using `get-host-entry`. Normally you do not need to, because all the interface functions do it implicitly.

`service` specifies the port number to use. It can be either an integer, which explicitly specifies the port number, or a string, which is either a sequence of decimal digits specifying the port number or a port name that is looked up to find the port number. For example, for http connections the port number is 80. The function `get-service-entry` can be used to convert between port numbers and names.

When connecting a socket (for example by `open-tcp-stream`), `hostspec` and `service` are required arguments. When binding (for example `start-up-server`), `hostspec` (which is normally passed by the keyword argument `local-address`) can be `nil`, which means use the local host and allow any connections. `service` (which is normally passed by the keyword argument `local-port`) can be specified as 0 or `nil`, both values meaning that the operating system will select some appropriate port number.

If you have a `socket-stream` or a socket, you can find what socket address it is bound to by `socket-stream-address` or `get-socket-address`, and if it is connected, you can find what address it is connected to by `socket-stream-peer-address` or `get-socket-peer-address`.

## 25.4 Information about IP addresses

You can use the function `get-host-entry` to find the address of a domain name or the domain name of an address. It can also used to find multiple addresses and aliases.

You can use `get-socket-address`, `get-socket-peer-address` and `socket-stream-address` and `socket-stream-peer-address` to find the IP address of opened sockets.

You can use `get-default-local-ipv6-address` to find the local default IPv6 address.

You can use `get-ip-default-zone-id` to find the local default zone ID.

## 25.5 Waiting on a socket stream

The function `wait-for-input-streams` and `wait-for-input-streams-returning-first` are a convenient interface for waiting for input from socket streams. The standard I/O functions (`c1:read`, `c1:read-char` and so on) can also wait properly. You can also use `process-wait` and similar functions with `c1:listen` in the `wait-function`, but you will need to use `with-noticed-socket-stream`.

## 25.6 Special considerations

The host machine must be configured properly to handle IPv6 for the Lisp-Works interface to work with IPv6.

It is likely that all new machines can use IPv6.

### 25.6.1 IPv6 on Mac OS X

IPv6 addresses work properly on Mac OS X 10.6.

### 25.6.2 IPv6 on Windows XP

By default IPv6 addresses do not work on Microsoft Windows XP. To make it work on Windows XP, install the interface by executing this command in a console, as an administrator user:

```
netsh interface ipv6 install
```

This should not be needed on later versions of Microsoft Windows. Search for `netsh` on [technet.microsoft.com](http://technet.microsoft.com) for more information.

**Note:** LispWorks 7.0 and later versions do not support Windows XP.

## 25.7 Asynchronous I/O

The Asynchronous I/O API allows you to perform I/O operations that invoke a callback when they are complete, rather than synchronously calling a function that returns a value (like `c1:read-line`). This allows many operations to run in a single thread. When using this API, you have to hold all of the application's state in data structures so that the callback can determine how to proceed.

There are two parts to the API:

- the Wait-State-Collection API controls the overall progress of I/O.
- the Async-I/O-State API deals with individual I/O channels.

### 25.7.1 The wait-state-collection API

A `wait-state-collection` is an object that controls asynchronous I/O via an event loop. Each I/O channel is associated with a wait-state in the collection (see the “The Async-I/O-State API” on page 412 for how to add channels to a collection).

Make a `wait-state-collection` using `make-wait-state-collection`, wait for I/O to occur using `wait-for-wait-state-collection`, process the I/O using `call-wait-state-collection` and close the collection using `close-wait-state-collection`.

The function `loop-processing-wait-state-collection` simplifies processing I/O by repeatedly calling `wait-for-wait-state-collection` and `call-wait-state-collection`. It can be stopped by `wait-state-collection-stop-loop`. The function `create-and-run-wait-state-collection` makes a `wait-state-collection` and a process that runs it (using `loop-processing-wait-state-collection`). In many cases, `create-and-run-wait-state-collection` is the only function that you need to use.

To call a function in the process associated with a `wait-state-collection` you can use `apply-in-wait-state-collection-process` (but see also “Writing callbacks in Asynchronous I/O operations” on page 414).

For the `wait-state-collection` to actually do anything, it must have some “wait-states” associated with it. The primary way of associating “wait-states” with a `wait-state-collection` is to create an `async-io-state` associated

with it, see “The Async-I/O-State API” on page 412 below. The function `accept-tcp-connections-creating-async-io-states` also creates an associated "wait-state", which itself creates an `async-io-state` associated with the `wait-state-collection`. Note that new `async-io-states` can be added (and removed) dynamically to the `wait-state-collection` from any process while it is working.

See

```
(example-edit-file "async-io/driver")
```

### 25.7.2 The Async-I/O-State API

The Async-I/O-State API contains functions to create and close various kinds of asynchronous I/O channels and perform input and output operations on them. Currently "I/O channel" means a socket or a `socket-stream`.

Each channel has an associated `async-io-state` object, which is used to retain information about the channel between calls to the input and output functions. You can store your own information using the `async-io-state-user-info` accessor and give the object a name for debugging purposes using the `async-io-state-name` accessor.

An `async-io-state` is created by any of these functions:

`create-async-io-state`

Takes a socket (an integer) or a `socket-stream` and allows I/O on the socket.

`create-async-io-state-and-connected-tcp-socket`

Takes a socket address to connect to, creates a TCP socket and connects it, and allows I/O on it.

`accept-tcp-connections-creating-async-io-states`

Takes a service and creates a listening socket that accepts connection and create states which allow I/O on the accepted connections.

`create-async-io-state-and-udp-socket`

Creates a UDP socket and allows I/O on it.

**create-async-io-state-and-connected-udp-socket**

Takes a socket address, creates a UDP socket and connect it, and allows I/O on it.

Once an **async-io-state** is created for an object, the object itself should not be used directly for I/O in the same direction (read or write). The **async-io-state** can then be made active by one of **async-io-state-read-buffer**, **async-io-state-write-buffer**, **async-io-state-read-with-checking**, **async-io-state-receive-message**, **async-io-state-send-message** and **async-io-state-send-message-to-address**.

Each **async-io-state** is associated with a **wait-state-collection** when it is created. For the **async-io-state** to be active, the **wait-state-collection** must be active, which means there must be a process calling **wait-for-wait-state-collection** and **call-wait-state-collection**, possibly via **loop-processing-wait-state-collection**.

The functions **async-io-state-read-buffer** and **async-io-state-write-buffer** create an I/O operation that reads or writes a fixed amount of data in a buffer. The operation finishes when the *callback* is called, or when when an *abort-callback* is called (after being set up by **async-io-state-abort**).

The function **async-io-state-read-with-checking** creates an input operation that periodically invokes a *callback* to determine whether enough data has been received, by examining the internal buffer. You can call **async-io-state-discard** to indicate that part of the internal buffer has been processed (for example parsed and converted to some data structure). The operation finishes when **async-io-state-finish** is called inside the *callback*, or when an *abort-callback* is called (after being set up by **async-io-state-abort**).

The function **async-io-state-receive-message** creates an input operation that receives a message (using **recv** or **recvfrom**). The functions **async-io-state-send-message** and **async-io-state-send-message-to-address** create an I/O operation that sends a message (using **send** or **sendto**). These three functions are intended to be used with states created with UDP sockets.

While an input operation is ongoing, you cannot start another input operation with the same direction. While a write operation is ongoing, whether you can start another write operation depends on the keyword argument **:queue-output** which is used when the **async-io-state** is created. If **queue-input** was

`nil` (the default for TCP), then you cannot start another write operation while one is ongoing. If `queue-output` was supplied as non-`nil` (the default for UDP), you can start another write operation, and the operation gets queued and actually starts after all previously queued operations have finished.

When you no longer need the `async-io-state` you must close it by `close-async-io-state`. Normally, that would close the object of the `async-io-state` too. `close-async-io-state` can be told to leave the object alive, so you can do further I/O with it. However, if you have read using `async-io-state`, it may have buffered data which you will need to deal with by `async-io-state-buffered-data-length` and `async-io-state-get-buffered-data` (unless you can just ignore it).

An `async-io-state` can have a *name*, to help identifying it, mainly for debugging. The default names that different functions give help to identify the kind of object that the state has.

See

```
(example-edit-file "async-io/multiplication-table")
(example-edit-file "async-io/print-connection-delay")
(example-edit-file "async-io/udp")
```

### 25.7.3 Writing callbacks in Asynchronous I/O operations

All of the Asynchronous I/O operations take a *callback*, which is called when the operation finished. The callbacks are called inside the same process that processes the `wait-state-collection` (specifically, the process that called `call-wait-state-collection`, potentially via `loop-processing-wait-state-collection`). That means that until the callback returns, no further processing happens on the `wait-state-collection`, and hence on any of the other `async-io-states` that are associated with it. Therefore callbacks need to be reasonably fast and not hang.

In general, the callbacks should be creating the next I/O operations, to ensure that that operations on each state are sequential (see “Asynchronous I/O and multiprocessing” on page 415). If this is a reasonably simple operation you just do it, but if the data for the next operation make take a long time to prepare you probably want to avoid doing it in the context of the callback. Things

that may cause it to take a long time include heavy computation or access to external resources that may cause delays.

A general solution is to send the work to another process, which will do the work and on completion will do the next I/O operation by calling the read/write `async-io-state` function.

Another possible solution is to perform operations that can be fast using one `wait-state-collection`, and perform slow operations on (an)other `wait-state-collection(s)`. This way a slow callback will only impede other slow callbacks. For example you may be accepting connections on the "fast" `wait-state-collection`, but communicate with the accepted connection on a slow `wait-state-collection` (pass `:create-state nil` to `accept-tcp-connections-creating-async-io-states`, and in the callback use `create-async-io-state` with another `wait-state-collection`). You may also decide to do the communication using streams and synchronous I/O (pass `:create-state nil` and in the *callback* use `(make-instance 'socket-stream ...)` and send the result to another process).

#### 25.7.4 Asynchronous I/O and multiprocessing

Processing of the `wait-state-collection` is not thread-safe, and for each collection there must be only one process at any one time calling any of these functions:

- `loop-processing-wait-state-collection`
- `call-wait-state-collection`
- `wait-for-wait-state-collection`
- `close-wait-state-collection`

`wait-state-collection-stop-loop` is thread-safe, and can be called on any thread at any time.

Adding and removing states to/from the collection is thread-safe with respect to the collection, which means that the creation functions like `create-async-io-state` can be called in parallel with any function that access the same collection, including themselves and the processing functions above. The same applies to functions that remove the state from the collection (`close-async-`

`io-state`), though these are not thread-safe with respect to the state (see below).

Note that the functions that create states use other resources which may have their own limitations. Most notably, local ports can be used only once at any time with the same protocol and family, so if you try to bind to a specific local port (by passing `local-port` to any of the functions or non-zero `service` in `accept-tcp-connections-creating-async-io-states`), you have to make sure that you do not do it with a port that is currently in use. (Note that `accept-tcp-connections-creating-async-io-states` may try several times).

The functions that actually do the I/O are not thread-safe with respect to the `state` argument, but are thread-safe with respect to the collection that the state is associated with. That means that they can be called in parallel to any function that accesses the collection that the state is associated with, but cannot be called in parallel to another function that tries to do I/O on the same `state` and `direction`. Moreover, the read functions cannot be called while there is an ongoing read operation, and the write function can be called while another write operation is ongoing only if `queue-output` is non-nil when creating the state. The function `close-async-io-state` also cannot be called in parallel to any of the I/O functions.

Explicitly:

The reading functions `async-io-state-read-buffer`, `async-io-state-read-with-checking` and `async-io-state-receive-message` must not be called on the same `state` in parallel to any of themselves, or in the period between any call to any of themselves and the call to the `callback` in the case of `async-io-state-read-with-checking` or `async-io-state-receive-message`, or the call to `async-io-state-finish` in the case of `async-io-state-read-with-checking`, or `abort-callback`.

If `queue-output` was `nil` when the state was created (TCP default), the writing functions `async-io-state-write-buffer`, `async-io-state-send-message`, and `async-io-state-send-message-to-address` must not be called on the same `state` in parallel to any of themselves, or in the period between any call to any of themselves and the call to the `callback`, or `abort-callback`. If `queue-output` was non-nil when the `state` was created (UDP default), the writing functions can be called in parallel.

`close-async-io-state` must not be called on the same *state* in parallel to any of the reading or writing functions, or between a call to any of them at the end of their operation (the *callback*, `async-io-state-finish`, or the *abort-callback*).

The reading and writing functions are mutually thread-safe, that is any of the reading functions can be called in parallel to any of the writing functions.

The functions `async-io-state-abort` and `async-io-state-abort-and-close` are thread-safe, and be called at any time in parallel to any function.

`async-io-state-get-buffered-data` is not thread-safe, and must not be called in parallel to any other function that may modify the *state*.

`async-io-state-finish` and `async-io-state-discard` are not thread-safe, but can only be called inside the callback of `async-io-state-read-with-checking`, which will be always in the same process. The accessors of `async-io-state` are thread-safe.

In general, it is intended that you will cope with these thread-safe restrictions of I/O functions by calling them from the callbacks of the previous I/O operation, thus guaranteeing that the previous I/O operation finished. For example, if you need to write several buffers to a socket, you can call `async-io-state-write-buffer` with the first buffer, and with a callback that calls `async-io-state-write-buffer` with the next buffer. A natural place to put the information where to get the next buffer is the *user-info* of the `async-io-state`, which can be accessed using `async-io-state-user-info`. For example, assume you have an `async-io-state`, a list of buffers to send, and also on completion you want to call a function `finished` on some object:

```
(defun my-send-buffers (state buffers object)
  (setf (async-io-state-user-info state)
        (cons buffers object))
  (my-state-send-next-buffer state))

(defun my-state-send-next-buffer (state)
  (let ((info (async-io-state-user-info state)))
    (if-let (buffer (pop (car info)))
        (async-io-state-write-buffer
         state buffer
         #'(lambda (state buffer length)
             (declare (ignore buffer length))
             (my-state-send-next-buffer state)))
    (finished (cdr info)))))
```

In a real application the *user-info* is likely to be a more complex object.

If you make the *state* with *queue-output t*, you can simply write all the buffers in one go:

```
(defun my-send-buffers (state buffers object)
  (setf (async-io-state-user-info state) object)
  (loop for cons on buffers
        do
        (async-io-state-write-buffer
         state (car cons)
         :callback
         (if (cdr cons) ; if there are more buffers
             #'(lambda (state buffer length)
                 (declare (ignore buffer length))
                 (finished
                  (async-io-state-user-info state))))))
  ))))
```

## 25.8 Using SSL

The SSL interface allows you to use Secure Socket Layer (SSL) with Lisp objects of type `socket-stream` and `async-io-state`.

The interface is based on the OpenSSL code, and most of it is simply an FLI interface to OpenSSL functions. The main LispWorks specific code is the way OpenSSL is integrated with `socket-stream` and `async-io-state`.

The SSL interface is part of the "`comm`" module, so to load it you evaluate

```
(require "comm")
```

**Note:** In this section we assume that the current package uses the `comm` package. That is, `comm` package symbols may not be qualified explicitly.

### 25.8.1 Obtaining and installing the OpenSSL library

At the time of writing, OpenSSL is available as shown in Table 25.1:

Table 25.1 OpenSSL availability

Operating System	Availability of OpenSSL
Linux	Installed by default on most 32-bit and 64-bit distributions

Table 25.1 OpenSSL availability

Operating System	Availability of OpenSSL
Windows	32-bit and 64-bit libraries are available at <a href="http://www.slproweb.com/products/Win32OpenSSL.html">www.slproweb.com/products/Win32OpenSSL.html</a>
Mac OS X	32-bit and 64-bit libraries are installed by default.
FreeBSD	Installed by default and available via ports or pkg.
AIX	Installed by default
x86/x64 Solaris	Installed by default
SPARC Solaris	Installed by default on Solaris 10. For other versions, see the freeware from Sun at <a href="http://sunfreeware.com">sunfreeware.com</a> for both 32-bit and 64-bit.

### 25.8.1.1 Installing the OpenSSL library on Solaris

After installing (with pkgadd) you need to put the shared libraries `libcrypto.so` and `libssl.so` on the loader path. By default these are installed in `/usr/local/ssl/lib`.

To add the libraries to the loader path, either

- Add `/usr/local/ssl/lib` to the environment variable `LD_LIBRARY_PATH`, or
- Create links from `/usr/lib`.

### 25.8.1.2 How LispWorks locates the OpenSSL libraries

Since OpenSSL is not a standard on all machines yet, the location of the library or libraries varies. By default, `ensure-ssl` loads libraries as shown in Table 25.2, page 420.

Table 25.2 How LispWorks locates the OpenSSL libraries

Operating System	Libraries
Linux	<code>-lssl</code>
Windows	<code>libeay32.dll</code> <code>libssl32.dll</code>
FreeBSD	<code>-lcrypto -lssl</code>
Solaris	<code>-lssl</code>
AIX	<code>-lssl</code>
Mac OS X	<code>-lssl</code>
Others	<code>nil</code>

On machines where the path is unknown or is incorrect, you must set the path by calling `set-ssl-library-path`, or by passing the path as the *library-path* argument to `ensure-ssl`. In particular, if you want to use the Windows OpenSSL 1.1 libraries from the page that is mentioned in the table “OpenSSL availability” on page 418, then the library names have changed and you will have to set the path. With the download from that page from September 2017, the names need to be:

```
64-bit      ("libssl-1_1-x64.dll"
              "libcrypto-1_1-x64.dll")
32-bit      ("libssl-1_1.dll"
              "libcrypto-1_1.dll")
```

### 25.8.2 Creating a stream with SSL

There are three ways to make a `socket-stream` with SSL processing:

- Call `(make-instance 'socket-stream :ssl-ctx ...)`
- Call `open-tcp-stream` with the `:ssl-ctx` keyword.
- Call `attach-ssl` on a `socket-stream`.

These calls implicitly load the OpenSSL library and seed the Pseudo Random Number Generator (PRNG).

For example:

```
(open-tcp-stream some-url 443 :ssl-ctx t)
```

### 25.8.3 Using Asynchronous I/O with SSL

There are three ways to make an `async-io-state` with SSL processing:

- Call `create-async-io-state-and-connected-tcp-socket` with the `:ssl-ctx` keyword.
- Call `accept-tcp-connections-creating-async-io-states` with the `:ssl-ctx` keyword.
- Call `async-io-state-attach-ssl` on an `async-io-state`.

These calls implicitly load the OpenSSL library and seed the Pseudo Random Number Generator (PRNG).

### 25.8.4 Keyword arguments for use with SSL

The keyword arguments `:ssl-ctx`, `:ssl-side`, `:ctx-configure-callback`, `:ssl-configure-callback` and `:handshake-timeout` can be passed to create and configure socket streams and `async-io-states` with SSL processing. The various interface calls for creating and configuring SSL streams and

async-io-states accept these keyword arguments as shown in Table 25.3, page 422.

Table 25.3 SSL configuration keywords

Keyword and Interface call	:ssl-ctx	:ssl-side	:ctx-configure-callback	:ssl-configure-callback	:handshake-timeout
<b>socket-stream make-instance</b>	Yes	Yes	Yes	Yes	Yes
<b>open-tcp-stream</b>	Yes	No	Yes	Yes	Yes
<b>attach-ssl</b>	Yes	Yes	Yes	Yes	Yes
<b>make-ssl-ctx</b>	Yes	Yes	No	No	Yes
<b>accept-tcp-connections-creating-async-io-states</b>	Yes	Yes	Yes	Yes	Yes
<b>create-async-io-state-and-connected-tcp-socket</b>	Yes	No	Yes	Yes	Yes
<b>async-io-state-attach-ssl</b>	Yes	Yes	Yes	Yes	Yes

(**make-instance 'socket-stream ...**) and **open-tcp-stream**, when **ssl-ctx** is non-nil, call **attach-ssl** and pass it all the arguments. **accept-tcp-connections-creating-async-io-states** and **create-async-io-state-and-connected-tcp-socket** when **ssl-ctx** is non-nil attach the ssl similar to the way **async-io-state-attach-ssl** does.

`:ssl-ctx` specifies that SSL should be used, and also specifies the SSL\_CTX object to use. See the OpenSSL manual entry for `SSL_CTX_new` for details of making a SSL\_CTX. The value of `ssl-ctx` can be:

A symbol

Together with `ssl-side`, this symbol specifies which protocol to use. `ssl-ctx` can be one of:

- 1) `t` or `:default`, meaning use the default. Currently this is the same as `:v23`.
- 2) One of `:v2`, `:v3`, `:v23` or `:tls-v1`. These are mapped to the `SSLv2_*`, `SSLv3_*`, `SSLv23_*`, `TLSv1_*` methods.

LispWorks makes a new SSL\_CTX object and uses it and frees it when the stream or state is closed. The interface calls also make an SSL object, uses it and frees it when the stream or state is closed.

A foreign pointer of type `ssl-ctx-pointer`

This corresponds to the C type `SSL_CTX*`. This is used and is not freed when the stream is closed. The interface calls also make an SSL object, use it and free it when the stream is closed. The foreign pointer maybe a result of a call to `make-ssl-ctx`, but it can also be a result of your code, provided that it points to a valid SSL\_CTX and has the type `ssl-ctx-pointer`.

A foreign pointer of type `ssl-pointer`

This corresponds to the C type `SSL*`. This specifies the SSL to use in the interface calls. This may be a result of a call to `ssl-new`, but can also be a result of your code, provided that it points to a valid SSL object and has the type `ssl-ctx-pointer`. The SSL is used and is not freed when the stream is closed.

When you pass a `ssl-ctx-pointer` or a `ssl-pointer` foreign pointer, these must have already been set up correctly and you are responsible for freeing them when they are no longer required.

`:ssl-side` specifies which side the stream is. The value `ssl-side` can be one of `:client`, `:server` or `:both`. `open-tcp-stream` and `create-async-io-state-and-connected-tcp-socket` do not take this keyword and always use `:client`. For the other calls this argument defaults to `:server`. The value of `ssl-side` is used in three cases:

- When a new SSL\_CTX object is created, it is used to select the method:  
`:client => *_client_method`  
`:server => *_server_method`  
`:both => *_method`
- When `ssl-ctx` is of type `ssl-ctx-pointer`, it checks that the side of `ssl-ctx` and `ssl-side` are not conflicting. If one is `:client` and the other is `:server`, they conflict and an error is signaled.
- When a new SSL object is created, when `ssl-side` is either `:client` or `:server`, LispWorks calls `ssl-set-connect-state` or `ssl-set-accept-state` respectively.

When a new SSL object is created, `ssl-side` is `:client` and `handshake-timeout` is greater than 0, a handshake is performed immediately.

If `ssl-ctx` is of type `ssl-pointer` then `ssl-side` is ignored.

`:ctx-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-ctx-pointer`. This is called immediately after a new SSL\_CTX is created. If the value of `ssl-ctx` is not a symbol, `ctx-configure-callback` is ignored.

`:ssl-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-pointer`. This is called immediately after a new SSL is created. If the value of `ssl-ctx` is a `ssl-pointer`, `ssl-configure-callback` is ignored.

When a handshake is performed immediately (`ssl-side` is `:client` and `ssl-ctx` is not a `ssl-ctx-pointer`), `handshake-timeout` specifies the time in seconds to wait for the handshake to complete. If `handshake-timeout` is `nil` (the default) then it waits forever. If the handshake fails or times out, it is an error situation: for the synchronous interface (stream) an error is signaled, and for the asynchronous interface the callback is called with an error indicator (see the spe-

cific functions for details). Note that `handshake-timeout 0` (or negative) prevents the handshake.

In typical usage, you will create few `ssl-ctx-pointer` objects (maybe only one), configure them as appropriate for your application and the machine that it runs on, and then use one of these as `ssl-ctx` in all of your calls. If some connections need special configuration, you will use `ssl-configure-callback` to configure the `ssl-pointer` of this connection. Sometimes when you open a connection as a client it may be sufficient to pass a symbol for `ssl-ctx`. Passing an `ssl-pointer` as `ssl-ctx` is for special cases.

### 25.8.5 Attaching SSL to an existing socket

You can attach SSL to an existing `socket-stream` by calling `attach-ssl` on the stream. The `socket-stream` SSL keyword arguments are processed by `attach-ssl` as described in “Keyword arguments for use with SSL” on page 421.

Detach SSL from a `socket-stream` and shut down the SSL with `detach-ssl`.

For full descriptions see `attach-ssl`, page 554 and `detach-ssl`, page 575.

You can attach SSL to an existing `async-io-state` by calling `async-io-state-attach-ssl` on the state, and detach it using `async-io-state-detach-ssl`.

Notes:

After an object (stream or state) has been detached, you can attach SSL to it again.

Detaching frees any automatically generated SSL objects in the same way that closing a stream or state does.

The SSL objects are attached to the `socket-stream` or `async-io-state`, rather than to the socket. Therefore if you want to move a socket to another object then you need to attach it again.

For example, if you have attached SSL to an `async-io-state` and then want to change to synchronous communication, you need to close the `async-io-state` by `close-async-io-state` with `keep-alive true` (effectively detach the

SSL), and then call `make-instance` with `socket-stream` with the socket plus `SSL-CTX` and any other necessary arguments.

To move the other way, from synchronous to asynchronous, use `replace-socket-stream-socket` with `socket nil` to disconnect the socket from the stream (which effectively calls `detach-ssl`), call `create-async-io-state` with the socket, and then call `async-io-state-attach-ssl` on the new `async-io-state`.

### 25.8.6 OpenSSL interface

The configuration interface contains mostly FLI function definitions that map directly to OpenSSL calls. See below for a list of those provided.

There are also some functions to make common cases simpler. These are `read-dhparams`, `pem-read`, `set-ssl-ctx-options`, `set-ssl-ctx-password-callback`, and `set-ssl-ctx-dh`.

#### 25.8.6.1 OpenSSL constants

The Lisp constants `SSL_FILETYPE_ASN1` and `SSL_FILETYPE_PEM` representing file types are provided.

#### 25.8.6.2 Naming conventions for direct OpenSSL calls

This section describes the mapping between OpenSSL function names and the corresponding Lisp names.

#### 25.8.6.3 Mapping C names to Lisp names

For functions that map directly to OpenSSL calls, the convention is to create the LISP name from the C name by replacing underscores by hyphens.

#### 25.8.6.4 Mapping Lisp names to C names

To find the C name from the LISP function name:

1. the hyphens need to be replaced by underscores, and
2. the initial SSL or SSL\_CTX has to be in uppercase, and

3. the rest has to be lowercase, except that
4. the following phrases are cased specially, like this: "RSAPrivateKey", "DSH", "ASN1", "CA", "PrivateKey"

### 25.8.7 Direct calls to OpenSSL

The following functions map directly to the OpenSSL functions. Check the OpenSSL documentation for details.

Where an OpenSSL function takes an `SSL*` or `SSL_CTX*`, the Lisp function's argument must be a foreign pointer of type `ssl-pointer`, `ssl-ctx-pointer` or `ssl-cipher-pointer`. Where an OpenSSL function takes a `char*` or `int`, the Lisp function's argument must be a string or integer. Where an OpenSSL function takes other kinds of pointers, the Lisp function's argument must be a foreign pointer. The return values are integers or foreign pointers unless stated otherwise.

If an error occurs in one of these functions, an error code is returned. They do not signal any Common Lisp conditions and so you should check the return value carefully.

Table 25.4 Direct calls to OpenSSL

Lisp function	Return values
<code>ssl-add-client-ca</code>	
<code>ssl-cipher-get-bits</code>	First value is number of bits the cipher actually uses. Second value is number of bits the algorithm of the cipher can use (which may be higher).
<code>ssl-cipher-get-name</code>	string. e.g. "DHE-RSA-AES256-SHA"
<code>ssl-cipher-get-version</code>	string. e.g. "TLSv1/SSLv3"
<code>ssl-clear-num-renegotiations</code>	

Table 25.4 Direct calls to OpenSSL

<code>ssl-use-rsaprivatekey-file</code>	
<code>ssl-use-privatekey-file</code>	

If you need OpenSSL functionality that is not provided here, you can define your own foreign functions via the LispWorks Foreign Language Interface.

If you do this, an important point to note is that on Microsoft Windows, the `:calling-convention` must be `:cdecl` (it defaults to `:stdcall`). If using OpenSSL suddenly causes mysterious crashes, the *calling-convention* in your foreign function definitions is the first thing to check.

### 25.8.8 Using SSL objects directly

The C objects SSL and SSL\_CTX are represented in LispWorks by foreign pointers with type `ssl-pointer` and `ssl-ctx-pointer`, which correspond to the C types SSL\* and SSL\_CTX\*. These foreign types should be used for any foreign function that takes or returns these C types, and must be used when passing a foreign pointer as the value of the `:ssl-ctx` argument.

Making SSL objects is a way of getting access to them to perform configuration, but, especially in the case of the SSL\_CTX, it is a useful way to avoid repeated calls to the configuration routines which may be time consuming. For example, if we have defined a function `configure-a-ctx`, and we want to read once every 60 seconds from some URL, we can write:

```
(loop (with-open-stream
          (str (comm:open-tcp-stream some-url 443 :ssl-ctx t
                                      :ctx-configure-callback
                                      'configure-a-ctx))
            (read-something str))
      (sleep 60))
```

This will cause `configure-a-ctx` to be called each time. If it is expensive, we can call it only once by changing the code to:

```
(let ((ctx (comm:make-ssl-ctx :ssl-side :client)))
  (configure-a-ctx ctx)
  (loop (with-open-stream
          (str (comm:open-tcp-stream some-url 443 :ssl-ctx ctx))
          (read-something str))
        (sleep 60))
  (comm:destroy-ssl-ctx ctx))
```

The SSL objects could be made either by `make-ssl-ctx` or `ssl-new` or by user code that calls the C functions `SSL_CTX_new` and `SSL_new`. `destroy-ssl-ctx` frees the `SSL_CTX` object. To free an SSL object you would call `destroy-ssl`. See the manual entries for full descriptions of these functions.

Alternatively, the SSL objects can be obtained from a `socket-stream` by calling `socket-stream-ssl` or `socket-stream-ctx` and from an `async-io-state` by calling `async-io-state-ssl` or `async-io-state-ssl1`. You can also find the `ssl-side` value that was passed to the interface call that created the SSL objects by calling `socket-stream-ssl-side` or `async-io-state-ssl-side`.

### 25.8.9 Initialization

All the functions that make a `SSL_CTX` first call `ensure-ssl`, so normally you do not need to initialize the library. If your code makes a `SSL_CTX` itself (that is, not by calling any of the LispWorks interface functions), it needs to initialize the library first. Normally that should be done by an explicit call to `ensure-ssl`, which loads the SSL library and calls `SSL_library_init` and `SSL_load_error_strings`, and also does some LispWorks specific initializations. If your code must do the initialization, `ensure-ssl` should still be called with the argument `:already-done t`, which tells it that the library is already loaded and initialized.

### 25.8.10 Errors in SSL

If there are errors inside SSL, LispWorks will signal an error of type `ssl-condition`, which is a subclass of `socket-error`.

The condition can be one of the types `ssl-x509-lookup`, `ssl-closed`, `ssl-error` and `ssl-failure`. See the manual pages for details of these condition classes.

### 25.8.11 Examples of using the socket stream SSL interface

See the example files in:

```
(example-edit-file "ssl/")
```

## 25.9 Socket streams with Java sockets and SSL on Android

Socket streams can now be implemented on top of Java Objects, instead of native sockets. The main purpose of this is to allow using SSL in LispWorks for Android Runtime, because OpenSSL is not available on Android. It may also be useful where you have a Java socket from some source and want to communicate through it using a Lisp stream.

The function `switch-open-tcp-stream-with-ssl-to-java` is called automatically before delivery for Android by `deliver-to-android-project`. That causes `open-tcp-stream`, when it is called with `ssl-ctx` non-nil, to use Java sockets instead of operating system sockets.

The function `open-tcp-stream-using-java` can be used to force using a Java socket.

You can also explicitly create a stream using Java sockets by passing a Java socket to `(make-instance 'comm:socket-stream ...)` or by setting the socket in an existing stream using `(setf comm:socket-stream-socket)` or `replace-socket-stream-socket`.

Socket streams with Java sockets are limited, mainly because `cl:listen` cannot be used reliably with them. Specifically, when `cl:listen` returns `t` it is guaranteed that reading will not hang, but when `cl:listen` returns `nil` it does not mean that there is nothing to read. They also do not have a zero timeout: the shortest timeout is 1 millisecond. That means that it is impossible to check whether reading from the stream will hang. The best that you can do is to set the `read-timeout` to a short time, and then try to read.

There is also no write timeout.

The Asynchronous I/O interface and the server side (`start-up-server`) do not work at the moment with Java sockets. If you want to create a service with Java sockets, you will need to implement the listening part using Java methods. Once a socket is accepted, you can pass it to `(make-instance 'comm:socket-stream ...)` to do the actual communication.

When using Java sockets, the SSL configuration arguments `ctx-configure-call-back` and `ssl-configure-call-back`, as well as the `write-timeout` and `ipv6`, are ignored. The `ssl-ctx` is ignored when passed to `c1:make-instance`, and when passed to `open-tcp-stream` or `open-tcp-stream-using-java` it is interpreted as a boolean, specifying whether to use SSL or not. The only way to configure the socket, and more importantly the SSL settings, is by passing a socket factory (a Java object of class `javax.net.SocketFactory`) to `open-tcp-stream-using-java`. The application needs to set up and configure this factory using Java methods. By default, `open-tcp-stream` and `open-tcp-stream-using-java` use the default factory (which they get by the method "`getDefault`" on `javax.net.SocketFactory` or `javax.net.ssl.SSLSocketFactory`). Thus configuring the default factories affects what they do.

`c1:listen` is unreliable because the only way to check whether there is input on a Java socket is to use the Java method "`available`" on the input stream of the Java socket (that is, the result of the method "`getInputStream`"). The "`available`" method is documented as unreliable, and experimentally it is indeed unreliable on SSL sockets (on plain sockets it seems to work properly). If you know that in the implementation that you use the method "`available`" on an input stream of a socket is reliable, then you can trust `c1:listen` on socket streams with Java sockets.

Using Java sockets requires the LispWorks Java interface running Java Virtual Machine (JVM). On Android there is always a running JVM. On other architectures the JVM must be initialized by `init-java-interface`. To load the LispWorks Java interface, do

```
(require "java-interface")
```

When using Java sockets and SSL, the default behavior is to verify the host-name (not done on the ordinary sockets). To do that it relies on classes from `httpclient` from `apache.org`, so `httpclient` must be in the class path for using Java sockets with SSL. `httpclient` is always available on Android. See `open-tcp-stream-using-java` for details of the verification process.

### 25.9.1 Android-specific points

On Android, the OpenSSL library is not available, so if the module "comm" was loaded, `deliver-to-android-project` switches to using Java sockets

for SSL streams. These streams have problems with `c1:listen`, discussed above. In principle, if you can find OpenSSL library for Android you can switch it back by calling `switch-open-tcp-stream-with-ssl-to-java` with `nil`, and use SSL in the usual way. You need to use `set-ssl-library-path` to tell the system where to find the library.

Android does not allow doing socket operations on the GUI threads (since Honeycomb SDK), and doing such operations would give a `java-exception` error with exception `NetworkOnMainThreadException`. That applies to `socket-stream` where the socket is a Java socket. However, it is always a bad idea to do socket operations on the GUI thread, so you should not do socket operations in the GUI thread with ordinary sockets either.

# 26

# Internationalization: characters, strings and encodings

## 26.1 Introduction

LispWorks uses Unicode internally in its representation of character objects. All Unicode characters can be represented in strings, though 8-bit and 16-bit strings are also provided for efficiency when characters beyond the Latin-1 range (up to code `#xffff`) or the BMP (Basic Multilingual Plane, up to code `#xffffffff`) respectively are not needed.

Character and string data can be input and output in various encodings (external formats).

## 26.2 Unicode support

Character implementation in LispWorks covers the full range of the Unicode standard.

`cl:char-code-limit` is `#x110000`, which covers exactly the Unicode range. The surrogate code points (codes `#xd800` to `#xdffff`) are illegal as character codes.

`cl:code-char` accepts integers from 0 below `cl:char-code-limit`. Other values cause an error. For codes in the surrogate range it returns `nil`. Reading characters from streams and converting characters from foreign strings can generate characters in all the range (depending on the external-format used),

and can never generate character objects corresponding to surrogate code points.

`text-string` and `simple-text-string` take 32 bits per character and can store the full range of Unicode characters.

`simple-char` is now a synonym for `c1:character`, and is deprecated.

16-bit characters and 16-bit strings are implemented by types `bmp-char` and `bmp-string` and `simple-bmp-string` (BMP is Basic Multilingual Plane, the first plane (0 - #xffff) of Unicode). You may want to use `bmp-string` to minimize memory usage if you have an application with many 16-bit strings. That will work provided all the characters you ever use have codes less than `#x10000`. If all of the codes are below 256, you can use `base-string` instead.

**Note:** Character bits and font attributes are not supported. To deal with bits, use Gesture Spec objects (see `make-gesture-spec` and `coerce-to-gesture-spec`).

## 26.3 Character and String types

### 26.3.1 Character types

LispWorks supports all the characters in the Unicode range `[0, #x10ffff]`, excluding the surrogate range `[#xd800, #xdfff]`. Note that character objects corresponding to surrogate code points may be produced by some APIs in LispWorks, but not by the interfaces that you should normally use to generate characters and strings in Common Lisp (that is `c1:code-char`, reading from a stream, converting from a foreign string, loading and storing from or to strings).

The following subtypes of character are defined:

<code>base-char</code>	Characters with <code>c1:char-code</code> less than <code>base-char-code-limit</code> (256).
<code>bmp-char</code>	Characters with <code>c1:char-code</code> less than <code>#x10000</code> (BMP stands for Basic Multilingual Plane in Unicode).
<code>character</code>	All characters.

### 26.3.2 Compatibility notes

In LispWorks 6.1 and earlier versions, characters with codes up to #x10000 are supported, and surrogate code points are allowed.

`bmp-char` was new in LispWorks 7.0, and matches the range of characters in LispWorks 6.1 and earlier versions, except that surrogate code points are no longer valid.

In LispWorks 6.1 and earlier versions there is `simple-char` which is now a synonym for `c1:character`. Using `c1:character` is preferable and portable.

In LispWorks 6.1 and earlier versions character bits attributes are supported, and also some characters represent keyboard gestures. These are no longer supported.

### 26.3.3 Character Syntax

All simple characters have names that consist of `u+` followed by the code of the character in hexadecimal, for example `#\U+764F` is `(code-char #x764F)`.

The hexadecimal number must be 4-6 characters, for example `#\U+a0` is illegal. Use `#\U+00a0` instead.

Additionally, Latin-1 characters have names derived from the ISO10646 name, for example:

```
(char-name (code-char 190))
=>
"Vulgar-Fraction-Three-Quarters"
```

Names are also provided for space characters:

```
(name-char "Ideographic-Space")
=>
#\Ideographic-Space
```

Note that surrogate characters, that is the inclusive range `[#xd800, #xdfff]` are not acceptable, and trying to read such a character, for example `#\U+d835`, produces an error.

### 26.3.4 Compatibility notes

In LispWorks 6.1 and earlier versions you can specify bits in character names. This is illegal in LispWorks 7.0 and later.

In LispWorks 6.1 and earlier versions character codes are limited to less than `#x10000`, and surrogate code points are allowed.

### 26.3.5 String types

String types are supplied which are capable of holding each of the character types mentioned above. The following string types are defined:

`base-string` holds any `base-char`.

`bmp-string` holds any `bmp-char`.

`text-string` holds any `cl:character` (see “Character types” on page 436).

**Compatibility note:** `bmp-string` was new in 7.0. In LispWorks 6.1 and earlier versions there is `augmented-string`, this is now a synonym for `text-string` and is deprecated.

In LispWorks 6.1 and earlier versions, `text-string` could hold characters with codes less than `#x10000`.

The types above include non-simple strings - those which are displaced, adjustable or with a fill-pointer.

The Common Lisp type `string` itself is dependent on the value of `*default-character-element-type*` according to the rules for string construction described in “String Construction” on page 441. For example:

```

CL-USER 1 > (set-default-character-element-type 'base-char)
BASE-CHAR

CL-USER 2 > (coerce (list #\Ideographic-Space) 'string)

Error: #\Ideographic-Space is not of type BASE-CHAR.
1 (abort) Return to level 0.
2 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or :? for
other options.

CL-USER 3 : 1 > :a

CL-USER 4 > (set-default-character-element-type 'character)
CHARACTER

CL-USER 5 > (coerce (list #\Ideographic-Space) 'string)
" "

```

The following types are subtypes of `cl:simple-string`. Note that in the names of the string types, 'simple' refers to the string object and does not mean that the string's elements are `simple-chars`.

<code>simple-base-string</code>	holds any <code>base-char</code> .
<code>simple-bmp-string</code>	holds any <code>bmp-char</code> .
<code>simple-text-string</code>	holds any <code>cl:character</code> .

The Common Lisp type `simple-string` itself is dependent on the value of `*default-character-element-type*` according to the rules for string construction described in "String Construction" on page 441.

### 26.3.5.1 String types at run time

The type `string` (and hence `simple-string`) is defined by ANSI Common Lisp to be a union of all the character array types. This makes a call like

```
(coerce s 'simple-string)
```

ambiguous because it needs to select a concrete type (such as `simple-base-string` or `simple-text-string`).

When LispWorks is running with `*default-character-element-type*` set to `base-char`, it expects that you will want strings with element type `base-char`, so functions like `coerce` treat references to `simple-string` as if they were `(simple-array base-char (*))`.

If you call `set-default-character-element-type` with a larger character type, then `simple-string` becomes a union of the array types that are sub-types of that character type.

### 26.3.5.2 String types at compile time

The compiler always does type inferencing for `simple-string` as if `*default-character-element-type*` was set to `character`.

For example, when you declare something to be of type `simple-string`, the compiler will never treat it as `simple-base-string`. Therefore calls like

```
(schar (the simple-string x) 0)
```

will work whether `x` is a `simple-base-string`, `simple-bmp-string` or `simple-text-string`.

## 26.4 String accessors

`schar` works on any simple string object. However, for efficient string access when a simple string type is known, the following specialized accessors are provided:

<code>sbchar</code>	for <code>simple-base-string</code> .
<code>stchar</code>	for <code>simple-text-string</code> .

For `simple-bmp-string` there is no explicit accessor, but you can get the optimized access by declaring it as `simple-bmp-string`, and do the access using `cl:schar`.

You can also use declarations to optimize the access to `simple-base-string` and `simple-text-string`. In the case of `simple-base-string`, that means using only Common Lisp symbols, so it is fully portable.

## 26.5 String Construction

LispWorks constructs strings of a suitable type where sufficient information is available. Failing that, strings are constructed of type according to the value of `*default-character-element-type*`.

### 26.5.1 Default string construction

If the value of `*default-character-element-type*` is `base-char` then:

```
(make-string 3)
```

returns a `simple-base-string` and

```
(coerce sequence 'simple-string)
```

attempts to construct a `simple-base-string`. This will signal an error if any element of `sequence` is not a `base-char`.

If the value of `*default-character-element-type*` is `cl:character` then

```
(make-string 3)
```

returns a `simple-text-string` and

```
(coerce sequence 'simple-string)
```

attempts to construct a `simple-text-string`. This will signal an error if any element of `sequence` is not a `cl:character`.

Other string constructors also take their default from `*default-character-element-type*`. For instance, `with-output-to-string` and `make-string-output-stream` will construct a stream with element type determined by this variable and generate a string of the same element type.

Also the string reader will always construct a string of type determined by `*default-character-element-type*`, unless it sees a character of a larger type, in which case a suitable string is constructed. For example:

```
CL-USER 1 > (set-default-character-element-type 'character)
CHARACTER
```

```
CL-USER 2 > (type-of "ABC")
SIMPLE-TEXT-STRING
```

**Compatibility note:** In LispWorks 6.0 and earlier versions, the string reader would not always obey `*default-character-element-type*`, due to a bug.

### 26.5.2 String construction with known type

The parameter `*default-character-element-type*` merely provides the default behavior. If enough information is supplied, then a string of suitable type is constructed. For instance, the form:

```
(make-string 3 :initial-element #\Ideographic-Space)
```

constructs a string of a type that can hold its elements, regardless of the value of `*default-character-element-type*`.

Likewise, `format nil`, `princ-to-string`, `prin1-to-string` and `write-to-string` will return a string whose element type can hold all characters that are written.

Functions that have a sequence type specifier as an argument, such as `concatenate`, use it as described in “String types” on page 438.

### 26.5.3 Controlling string construction

The initial value of `*default-character-element-type*` is `base-char`, to avoid programs that only require 8-bit strings needlessly creating larger string objects. If your application uses Unicode characters beyond the Latin-1 range (characters of type `extended-char`) then you should consider which of the following two approaches to use:

- Ensure that all strings which may hold `extended-chars` are constructed explicitly with the appropriate type. This is the conservative approach, allowing you to avoid allocation of 16-bit strings where these are not required. Note that you can use the specialized accessors such as `stchar` for strings of type `simple-text-string`.
- Change the default so that by default 16-bit strings are allocated. Do this by:

```
(set-default-character-element-type 'cl:character)
```

Bear in mind that this is a global setting which affects default string construction for the entire system. It could be called from a user interface, depending on whether the user needs to handle `extended-chars`.

**Note:** Do not attempt to bind or set directly the variable `*default-character-element-type*`. Instead, call `set-default-character-element-type`.

#### 26.5.4 String construction on Windows systems

When LispWorks for Windows starts up on a OS with a non-Latin-1 code page, it calls

```
(set-default-character-element-type 'cl:character)
```

so that by default, newly constructed strings can contain the data likely to be returned from the OS or user input.

If you know your string only needs to contain 8-bit data, then you can create it explicitly with element type `base-char`.

Conversely if you know that a string may need to contain 16-bit data even on a Latin-1 code page system, then you should create it explicitly with element type `bmp-char` (or `cl:character` if 32-bit data is needed).

## 26.6 External Formats

External formats are two-way translations from Lisp's internal encoding to an external encoding. They can be used in file I/O, and in passing and receiving string data in foreign function calls.

An external format is named in LispWorks by an *external format specification* (*ef-spec*). An ef-spec is a symbol naming the external format, or a list with such a name as its first element followed by parameter/value pairs.

LispWorks has a number of predefined external formats:

`win32:code-page`

The Windows code page with identifier given by the `:id` parameter. Implemented only on Windows.

`:latin-1` ISO8859-1.

`:latin-1-terminal`

As Latin-1, except that if a non-Latin-1 character is output, it is written as <xxxx> where xxxx is the hexadecimal character code and does not signal error.

<b>:latin-1-safe</b>	As Latin-1, except that if a non-Latin-1 character is output, it is written as ? and does not signal error.
<b>:macos-roman</b>	The Mac OS Roman encoding.
<b>:ascii</b>	ASCII.
<b>:unicode</b>	<b>:utf-16</b> with default native byte order. See “16-bit External formats guide” on page 445 for details and variants.  <b>Compatibility note:</b> In LispWorks 6.1 and earlier versions, <b>:unicode</b> encodes 16-bit characters reading.
<b>:utf-8</b>	The UTF-8 encoding of Unicode.
<b>:utf-16</b>	The UTF-16 encoding of Unicode with big-endian byte order. See “16-bit External formats guide” on page 445 for details and variants.
<b>:utf-32</b>	The UTF-32 encoding of Unicode with big-endian byte order.  <b>Note:</b> There is a <b>:utf-32</b> external format corresponding to each of the <b>:utf-16</b> variants.
<b>:bmp</b>	Reads and writes 16-bit characters with native byte order. See “16-bit External formats guide” on page 445 for details and variants.
<b>:jis</b>	JIS. The encoding data is read from a file <code>uni2jis</code> and is pre-built into LispWorks.  <b>Note:</b> <code>uni2jis</code> is provided by way of documentation in the directory <code>lib/7-1-0-0/etc/</code> . It is also used at run time by the function <code>cl:char-name</code> .
<b>:euc-jp</b>	EUC-JP. The encoding data is read from a file <code>uni2jis</code> and is pre-built into LispWorks.
<b>:sjis</b>	Shift JIS.
<b>:windows-cp936</b>	

Windows code page 936. The encoding data is read from a file `windows-936-2000.ucm` and is pre-built into LispWorks.

**Note:** `windows-936-2000.ucm` is provided by way of documentation in the directory `lib/7-1-0-0/etc/`. It is not read at run time.

`:gbk` A synonym for `:windows-cp936`.

`:koi8-r` The KOI8-R (RFC 1489) encoding.

## 26.7 16-bit External formats guide

### 26.7.1 Unicode

In LispWorks 6.1 and earlier versions the external format `:unicode` is actually "raw UCS-2", that is reading and writing only 16-bit characters (including character objects corresponding to surrogate code points). The `:unicode` format now maps to `:utf-16` with the native endianness (by default). This interprets surrogate code points (`#xd800` to `#xdffff`) differently: the old `:unicode` would read these as if they are actual characters, while `:utf-16` and hence the new `:unicode` will try to interpret them as encoding supplementary characters (codes `#x10000` to `#x10ffff`). The latter behavior is probably what you need, so in most cases there is no need to replace usage of `:unicode`. There is no external format which interprets surrogate code points as characters now, but you can use any of the `:bmp` formats with `:use-replacement t` to read 16-bit characters without giving an error, although this does not exactly match the input, because surrogate code points are translated by the replacement character. The only format that can read anything without any loss is `:latin-1`.

Note that `:unicode` differs from `:utf-16` by the default byte order that it uses: `:utf-16` defaults to big-endian (matching the Unicode standard), while `:unicode` defaults to the native byte order.

## 26.7.2 UTF-16

There are now several UTF-16 external formats. There are more than one because UTF-16 is actually two different encodings: UTF-16 big-endian and UTF-16 little-endian.

`:utf-16-native` and `:utf-16-reversed` are the actual implementation formats. They implement UTF-16 with the native byte order (`:utf-16-native`) or the reversed byte order (`:utf-16-reversed`)

`:utf-16be` and `:utf-16le` implement the big-endian (`:utf-16be`) and little-endian (`:utf-16le`) UTF-16. The system maps these formats to `:utf-16-native` or `:utf-16-reversed` as appropriate, depending on the byte order of the computer.

`:utf-16` implements the UTF-16 standard, defaulting to UTF-16BE unless there is a BOM (Byte Order Mark).

In general, you will need to decide which of these to use depending on the circumstances.

## 26.7.3 BMP

There are now a few BMP external formats, which read and write only 16-bit characters (characters in the range `0` to `#xffff`, excluding the surrogate range `#xd800` to `#xdffff`).

`:bmp-native` and `:bmp-reversed` are the actual implementation formats. They implement reading 16-bit characters with the native byte order (`:bmp-native`) or the reversed byte order (`:bmp-reversed`). These formats never read supplementary characters. When they encounter a surrogate code point, they either signal an error or replace it by the replacement character, depending on the parameter `:use-replacement`.

`:bmp` implements 16-bit character reading and writing, defaulting to the native one.

**Notes:** In LispWorks 6.1 and earlier versions, the `:unicode` external format is similar to `:bmp` now, but handles surrogate code points as if they represent

characters. In LispWorks 7.0 and later `:unicode` maps to `:utf-16`, and there is no external format that reads surrogate code points as characters.

## 26.8 External Formats and File Streams

The `:external-format` argument of `open` and related functions should be an ef-spec, where the name can be `:default`. The symbol `:default` is the default value.

If you know the format of the data when doing file I/O, you should definitely specify *external-format* explicitly, in the ef-spec syntax described in this section.

### 26.8.1 Complete external format ef-specs

An ef-spec is "complete" if and only if the name is not `:default` and the parameters include `:eol-style`.

All external formats have an `:eol-style` parameter. If *eol-style* is not explicit in an ef-spec a default is used. The allowed values are

- `:lf` This is the default on non-Windows systems, meaning that lines are terminated by Linefeed.
- `:crlf` This is the default on Windows, meaning that lines are terminated by Carriage-Return followed by Linefeed.
- `:cr` Lines are terminated by Carriage-Return.

### 26.8.2 Using complete external formats

If `open` or `with-open-file` gets a complete `:external-format` argument then, it is used as is. For example, this form opens an ASCII linefeed-terminated stream:

```
(with-open-file (ss "C:/temp/ascii-lf"
                     :direction :output
                     :external-format
                     '(:ascii :eol-style :lf))
  (stream-external-format ss))
=>
(:ASCII :EOL-STYLE :LF)
```

If you know the encoding of a file you are opening, then you should pass the appropriate `:external-format` argument.

### 26.8.3 Guessing the external format

If `open` or `with-open-file` gets a non-complete `:external-format` argument `ef-spec` then the system decides which external format to use by calling the function `guess-external-format`.

The default behavior of `guess-external-format` is as follows:

1. When `ef-spec`'s name is `:default`, this finds a match based on the file-name; or (if that fails), looks in the Emacs-style (-\*) attribute line for an option called `ENCODING` or `EXTERNAL-FORMAT` or `CODING`; or (if that fails), chooses from amongst likely encodings by analysing the bytes near the start of the file, or (if that fails) uses a default encoding. Otherwise `ef-spec`'s name is assumed to name an encoding and this encoding is used.
2. When `ef-spec` does not include the `:eol-style` parameter, it then also analyzes the start of the file for byte patterns indicating the end-of-line style, and uses a default end-of-line style if no such pattern is found.

The file in this example was written by a Windows program which writes the Byte Order Mark at the start of the file, indicating that it is Unicode encoded. The routine in step 1 above detects this:

```
(set-default-character-element-type 'character)
=>
CHARACTER

(with-open-file (ss "C:/temp/unicode-notepad.txt")
  (stream-external-format ss))
=>
(:UNICODE :LITTLE-ENDIAN T :EOL-STYLE :CRLF)
```

The behavior of `guess-external-format` is configurable via the variables `*file-encoding-detection-algorithm*` and `*file-eol-style-detection-algorithm*`. See the manual pages for details.

### 26.8.3.1 Example of using UTF-8 by default

To change the default for all file access via `open`, `compile-file` and so on, you can modify the value of `*file-encoding-detection-algorithm*`.

For example given the following definition:

```
(defun utf-8-file-encoding (pathname ef-spec buffer length)
  (declare (ignore pathname buffer length))
  (system:merge-ef-specs ef-spec :utf-8))
```

then this makes it use UTF-8 as a fallback:

```
(setq system:*file-encoding-detection-algorithm*
      (substitute 'utf-8-file-encoding
                   'system:locale-file-encoding
                   system:*file-encoding-detection-algorithm*))
```

and this forces it to always use UTF-8:

```
(setq system:*file-encoding-detection-algorithm*
      '(utf-8-file-encoding))
```

### 26.8.3.2 Example of using UTF-8 if possible

The example in “Example of using UTF-8 by default” on page 449 will use UTF-8 even if the file is known to contain bytes that cannot be in this encoding. As an alternative way to use UTF-8 when possible, you can modify the value of `*specific-valid-file-encodings*`.

For example:

```
(pushnew :utf-8 system:*specific-valid-file-encodings*)
```

### 26.8.4 External formats and stream-element-type

The `:element-type` argument in `open` and `with-open-file` defaults to the value of `*default-character-element-type*`.

If `element-type` is not `:default`, checks are made to ensure that the resulting stream’s `stream-element-type` is compatible with its external format:

1. If `direction` is `:input` or `:io`, the `element-type` argument must be a supertype of the type of characters produced by the external format.

2. If *direction* is :output or :io, the *element-type* argument must be a subtype of the type of characters accepted by the external format

If the *element-type* argument does not satisfy these requirements, an error is signaled.

If *element-type* is :default the system chooses the `stream-element-type` on the basis of the external format.

### 26.8.5 External formats and the LispWorks Editor

The LispWorks Editor uses `open` with `:element-type :default` to read and write files. On reading a file, the external format is remembered and used when saving the file. On writing a Unicode (UTF-16) file, the Byte Order Mark is written.

It is possible to insert characters in the Editor (for example by pasting clipboard text) which are not supported by the chosen external format. This will lead to errors on attempt to save the buffer. You can handle this by setting the external format appropriately.

See the *LispWorks Editor User Guide* for more details.

### 26.8.6 Byte Order Mark

The Unicode Byte Order Mark (BOM) is treated as whitespace in the default readtable. This allows the Lisp reader to read a 16-bit (UTF-16 or BMP encoded) file regardless of whether the BOM is present. See “16-bit External formats guide” on page 445 for more information.

Some editors including Microsoft Notepad and the LispWorks editor write the BOM when writing a file with 16-bit (UTF-16 or BMP) encoding.

## 26.9 External Formats and the Foreign Language Interface

External formats can be used to pass and receive string data via the FLI. See the section on string types in the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

## 26.10 Unicode character and string functions

This section lists functions which compare characters and strings similarly to `cl:char-equal`, `cl:string-greaterp` and so on, but which use Unicode's simple case folding rules.

There are also predicates for properties of characters in Unicode's "general category", corresponding to `cl:alpha-char-p`, `cl:both-case-p` and so on.

### 26.10.1 Unicode case insensitive character comparison

The functions `unicode-char-equal`, `unicode-char-not-equal`, `unicode-char-lessp`, `unicode-char-not-lessp`, `unicode-char-greaterp` and `unicode-char-not-greaterp` compare characters similarly to `cl:char-equal` etc, but using Unicode's simple case folding rules.

### 26.10.2 Unicode case insensitive string comparison

The functions `unicode-string-equal`, `unicode-string-not-equal`, `unicode-string-lessp`, `unicode-string-not-lessp`, `unicode-string-greaterp` and `unicode-string-not-greaterp` compare strings similarly to `cl:string-equal` etc, but using Unicode's simple case folding rules.

### 26.10.3 Unicode character predicates

The predicates `unicode-alphanumeric-p`, `unicode-alpha-char-p`, `unicode-lower-case-p`, `unicode-upper-case-p` and `unicode-both-case-p` test for properties of a character in Unicode's "general category".

# LispWorks' Operating Environment

This chapter describes the interfaces which provide information about the environment in which LispWorks is running. This includes the operating system, the file system, the physical location of the LispWorks executable, and the arguments it was passed on startup.

## 27.1 The Operating System

The Common Lisp function `software-type` returns a generic name for the Operating System. The Common Lisp function `software-version` returns information about the version of the Operating System.

In particular `software-type` cannot be used to distinguish between different versions of Windows, whereas `software-version` allows you to identify variants such as Windows Vista, Windows 7, Windows 8, Windows 10 and so on. See the manual pages for details.

## 27.2 Site Name

The Common Lisp functions `short-site-name` and `long-site-name` can be configured using `setf`:

```
(setf (long-site-name) "LispWorks Ltd"  
      (short-site-name) "LW")
```

## 27.3 The Lisp Image

The function `lisp-image-name` returns the namestring of the full path of the LispWorks executable or dynamic library (DLL). For example, the directory of the image can be found using:

```
(pathname-location (lisp-image-name))
```

To create a new executable or DLL, typically after loading patches, modules and application code, use `save-image` or `deliver`.

**Note:** Microsoft Windows supports Long and Short forms of paths. You may need to convert a namestring using `long-namestring` or `short-namestring`.

## 27.4 The Command Line

The command line used to run LispWorks can be found using the variable `*line-arguments-list*`. The value is a list of strings containing the executable name followed by any other command line arguments, in the order they were passed.

For example, if your application needs to behave differently when passed an argument `-foo`, use the following test:

```
(member "-foo" sys:*line-arguments-list* :test 'string=)
```

### 27.4.1 Command Line Arguments

The following command line options are supported by the system.

**-build** *build-script*

Typically this is used for the purpose of building another image.

*build-script* can name a file to be loaded on startup. This file will be the build script which loads your code and calls `save-image` or `deliver`. LispWorks quits after loading the file. If an error is signaled while loading the file, a backtrace is displayed and LispWorks quits.

*build-script* can also be `-`, a single minus sign. Passing `-build -` causes LispWorks to read and execute a build script from stdin. This is useful if you want to embed a build script within a shell script that runs LispWorks, for example:

```
lispworks-7-1-0-x86-linux -build - <<END
(write-line "This is the build script.")
END
```

Note that this technique using `<<END` does not work on Microsoft Windows.

An image run with `-build` runs itself, and not the default saved session if you created one. See “Saved sessions” on page 182 for information on saved sessions.

`-build` calls `load-all-patches` automatically. There is no harm if your build script also calls `load-all-patches`.

**-environment** Start the LispWorks IDE development environment automatically, even in an image saved with (`save-image ... :environment nil`)

**-eval form** Evaluates the Lisp form *form* before loading initialization files.

If *form* requires multiprocessing, then change it to push a process specification onto `*initial-processes*`. This will delay evaluation until multiprocessing has started, either by the `-multiprocessing` command line options or because LispWorks was saved to start multiprocessing.

**-env** A synonym for `-environment`.

**-display display**

Sets the X display to use when starting a LispWorks GUI on X Windows.

**-IIOPHost host**

Controls the host name in placed in IORs. See *Developing Component Software with CORBA* for details.

**-IIOPnumeric**

IORs contain a host name which is the numeric IP address obtained by reverse lookup of the machine name. See *Developing Component Software with CORBA* for details.

**-init *init-file*** *init-file* names a file to be loaded on startup after *siteinit-file*.

The file is user's own LispWorks initialization file, containing code that by default is loaded when LispWorks is started. It is useful for loading initializations that should not be done for all users.

Initially the default is to load the file "`~/.lispworks`" where ~ expands to the user's home directory as described in "Configuration and initialization files" on page 178.

Your default initialization file can be set in the LispWorks IDE. See "Setting Preferences" in the *LispWorks IDE User Guide* for details.

If *init-file* is not found, an error is signaled. To suppress loading of a user initialization file, pass **-init -**.

**-load *file*** Loads the file *file* before loading initialization files.

**-lw-no-redirection**

Makes the supplied image run itself, and not the default saved session if you created one. See "Saved sessions" on page 182 for information on saved sessions.

**-multiprocessing**

Initializes multiprocessing on startup. See Chapter 19, "Multiprocessing".

**-no-restart-function**

Suppresses the execution of a restart function on startup. Restart functions can be supplied when saving an image to automatically invoke application code. This argument suppresses that behavior. See `save-image`, page 1001.

**-ORBport *orbport***

*orbport* specifies a port number for the LispWorks ORB. The special value 0 allows the system to pick a port.

**--relocate-image *BaseAddress***

Causes the image to relocate at *BaseAddress* on supported platforms, as described in “Startup relocation” on page 459. This can be useful on a system where libraries are mapped in address space that LispWorks would otherwise use as it grows. If the image is saved, then on restart without `--relocate-image`, it will locate itself automatically at *BaseAddress*.

**Compatibility note:** In LispWorks 5.0 and earlier versions, to be effective, `--relocate-image` must be the first argument on the LispWorks command line. This restriction does not apply in LispWorks 7.1.

**--reserve-size *ReserveSize***

Specifies the reserve size on supported platforms, as described in “Startup relocation” on page 459.

**-siteinit *siteinit-file***

*siteinit-file* names a file to be loaded on startup. The file is the LispWorks site initialization file, containing code that by default is loaded when LispWorks is started by any user in that installation. The default is to load the file that is the result of evaluating

`(sys:lispworks-file "config/siteinit.lisp")`.

If *siteinit-file* is not found, an error is signaled. To suppress loading of a site initialization file, pass `-siteinit -`.

### 27.4.2 Accessing environment variables

Use `environment-variable` get and set the value of an environment variable in the environment table of the OS process that called LispWorks.

To remove FOO from the environment table do:

```
(setf (lw:environment-variable "FOO") nil)
```

## 27.5 Address Space and Image Size

There are two factors that affect the maximum size of the Lisp image: the size of real memory, and the layout of memory. On most platforms you can relocate LispWorks to avoid clashes with other software as described in “Startup relocation” on page 459.

### 27.5.1 Size of real memory

If LispWorks becomes significantly larger than the size of the real memory, then paging will be the main activity and LispWorks will not function effectively.

### 27.5.2 Layout of memory

This is Operating System-dependent:

On Solaris, 32-bit LispWorks is mapped at `#x10000000`. In principle it can grow to almost `#x80000000` (the libraries are at higher addresses).

For the other platforms and for 64-bit LispWorks, see the discussion in “Startup relocation” on page 459.

### 27.5.3 Reporting current allocation

The simplest way to see the current Lisp allocation is to call `(room t)`.

To obtain values representing the current total allocation, call `room-values`.

## 27.6 Startup relocation

On startup, LispWorks normally maps its heap at the address where it was mapped when the image was saved. It maps more memory close to this when needed. This may cause memory clashes with other software, but such clashes may be avoided by relocating LispWorks.

32-bit LispWorks is relocatable on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris, FreeBSD and AIX. 64-bit LispWorks is relocatable on all supported platforms. The discussion in this section is applicable to all relocatable implementations.

On Microsoft Windows and Macintosh, LispWorks detects memory clashes and avoids them automatically. On these platforms there is no need to explicitly relocate LispWorks. The other relocatable implementations - LispWorks (32-bit) for Linux, LispWorks (64-bit) for Linux, LispWorks (32-bit) for FreeBSD, LispWorks (64-bit) for FreeBSD, LispWorks (32-bit) for x86/x64 Solaris, LispWorks (64-bit) for x86/x64 Solaris, LispWorks (64-bit) for SPARC/Solaris, LispWorks (32-bit) for AIX and LispWorks (64-bit) for AIX - cannot safely detect memory clashes. Relocation may therefore be useful in these implementations.

### 27.6.1 How to relocate LispWorks

Relocate LispWorks by passing two parameters: the base address and the reserve amount. Both are optional. The interpretation of these parameters is very different between 64-bit LispWorks and 32-bit LispWorks.

To relocate a LispWorks executable, pass one or both of these command line arguments:

**--relocate-image *BaseAddress***

The base address, interpreted as a hexadecimal number  
by calling `strtol(BaseAddress, NULL, 16)`)

**--reserve-size *ReserveSize***

The reserve size, interpreted as a hexadecimal number  
by calling `strtol(ReserveSize, NULL, 16)`)

On all relocatable platforms, a LispWorks dynamic library or Windows DLL can be relocated by calling `InitLispWorks` with second and/or third argument non-zero.

On non-Windows platforms, you can add the appropriate call to `InitLispWorks` in wrappers written in C and added to the dynamic library by passing *dll-added-files* to `save-image` or `deliver`. There is no such option in LispWorks for Windows.

The startup relocation takes some time, normally less than 0.1 seconds on a modern machine. If the relocation address is fixed and known, this startup overhead can be eliminated by relocating the image before calling `save-image` or `deliver`.

### 27.6.2 Startup relocation of 32-bit LispWorks

32-bit LispWorks on x86 platforms maps its heap in one continuous block, and then grows upwards from the top. When it reaches a region that it cannot use, it can skip it. On Windows and Macintosh this skipping is safe, because LispWorks can safely detect regions of memory that it cannot use. On other x86 platforms, both the initial mapping and the further growth cannot safely detect when they overwrite some other code.

`BaseAddress` (passed on command line with `--relocate-image` or as the second argument to `InitLispWorks`) tells LispWorks where to map the heap. On Windows and Macintosh, if the address is already used the heap will be mapped elsewhere. On other platforms, the mapping always works, and may destroy what is already mapped at that address.

`ReserveSize` (passed on command line with `--reserve-size` or as the third argument to `InitLispWorks`) tells LispWorks how much additional memory to reserve. Reservation is properly supported on Windows and Macintosh, though the actual reserved size can be smaller if it fails to reserve as much as was requested. On platforms that do not support reservation (that is, not Windows or Macintosh), the reservation is done by using `mmap` with protection `PROT_NONE`.

For a description of the memory layout on each platform, see “Memory layout” on page 140.

### 27.6.3 Startup relocation of 64-bit LispWorks

The size of address space that 64-bit LispWorks can use is limited by the size of internal tables to a "span" of  $2^{44}$  (16TB). The span always starts at 0.

Inside this span LispWorks can use any address. However, to avoid clashes with other software, it uses memory only in some defined range.

Startup relocation means changing this range. `BaseAddress` (passed on command line with `--relocate-image` or as the second argument to `InitLispWorks`, rounded up to  $2^{28}$ ) is the start of the range. `ReserveSize` (passed on command line with `--reserve-size` or as the third argument to `InitLispWorks`) is the size of the range. The default of the size of the range is  $2^{40}$ .

If the entire heap is within the new range, nothing else is done. If some part of the heap is outside the new range, the heap is relocated.

The range in each 64-bit LispWorks implementation starts at `#x4000000000` (256 GB).

#### 27.6.3.1 Linux

On old Linux systems LispWorks (64-bit) for Linux has range 192 GB, ending at `#x7000000000`, because old Linux systems cannot map above `#x8000000000` and put the dynamic libraries just below that limit (at least in some configurations). Since LispWorks uses the address space sparsely, it will run out of memory with less virtual memory, probably around 150 GB to 160 GB. If more memory is required, the range can be extended downwards, and possibly some distance upwards too. If other software uses memory in the range from `#x4000000000` to `#x7000000000`, LispWorks should be relocated (potentially just by decreasing the range) to avoid memory clashes.

Modern Linux systems have a much larger address space and the default size of the LispWorks range is `#x4000000000` (4TB).

#### 27.6.3.2 SPARC Solaris

In LispWorks (64-bit) for SPARC Solaris the default range is 768 GB, ending at `#x1000000000`. If other software uses memory in this range, the range for LispWorks should be decreased to avoid memory clashes.

### 27.6.3.3 Windows, Macintosh and AIX

In LispWorks (64-bit) for Windows, LispWorks (64-bit) for Macintosh and LispWorks (64-bit) for AIX the size of the range is `#x3c0000000000` (3.75TB). Since these platforms properly support reservation, there should not be any reason to change the range. The only time when this is needed is when other software insists on using some address in this range and does not relocate automatically.

## 27.7 Calling external programs

You can call an external program using `call-system`, `call-system-showing-output` and `open-pipe`.

You can call C programs using the FLI. See the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

On Microsoft Windows a COM/Automation interface is provided. See the *LispWorks COM/Automation User Guide and Reference Manual*. There is also a DDE interface - see Chapter 22, “Dynamic Data Exchange”.

On Mac OS X an Objective-C API is provided. See the *LispWorks Objective-C and Cocoa Interface User Guide and Reference Manual*.

### 27.7.1 Interpreting the exit status

`call-system` returns the exit status of the process it created, and potentially a signal number. Similarly `pipe-exit-status` can query the exit status and signal number associated with a process that was created by `open-pipe`.

On Unix-like systems when using a string as the command with a typical shell, the exit status is the exit status of the command that is executed. If it is an actual executable (rather than a built-in command) it is the exit status of the process that invoked by this executable. That is not always reliable. In a typical shell you can precede the last command by the word `exec` to cause the shell to replace itself by the executable, and then the return value is guaranteed to be from the executable. On Microsoft Windows and when not using string as a command, there is only one process and the exit status is the exit status of this process.

On Unix-like systems, on normal exit the exit status is the argument that was passed to the C function `exit` (or `_exit`) or the value returned from the main function, and the signal number is `nil`. To interpret the normal exit status you need to know what the process does. Normally 0 means success. If the process exited as a result of a signal then the second return value gives the number of the signal.

On Windows, the exit status is either the argument to `ExitProcess` or `TerminateProcess`, the return value of `main` or `WinMain`, or an exception value.

## 27.8 Snapshot debugging of startup errors

When an error occurs during initialization (for example, because of code in an initialization file) and the image is configured to start the LispWorks IDE, by default it catches the error, starts the IDE and displays the error in a snapshot debugger.

You should note that because this is a snapshot, you cannot actually continue or abort or return from a frame. The snapshot debugger is simply a tool to help debugging the error.

The behavior is controlled by the variable `*debug-initialization-errors-in-snap-shot*`.

## 27.9 System message log

The system message log is used by the system to produce messages that indicate that something is not as expected, where this is not an error. You can manipulate the log with `set-system-message-log`.

## 27.10 Exit status

You can return a process exit status to the Operating System when LispWorks or a delivered LispWorks application quits.

Do this by passing a `status` value to the function `quit`. For example:

```
(quit :status 42)
```

## 27.11 Creating a new executable with code preloaded

There are two ways to create a new executable with your code preloaded.

- To write a copy of the currently running image to disk, use `save-image`, page 1001. The saved image requires a development license key to run.
- To create a runtime image, removing unused code to make the image smaller, call `deliver`. For more details see the *LispWorks Delivery User Guide*.

For example of how to use `save-image`, see the section "Saving and testing the configured image" in the *LispWorks Release Notes and Installation Guide*.

See "Code signing in saved images" on page 181 for information about code signing your new executable.

## 27.12 User Preferences

LispWorks provides an API for setting and querying persistent per-user settings in a platform-dependent registry.

### 27.12.1 Location of persistent settings

On Microsoft Windows the preferences are stored in the HKEY\_CURRENT\_USER branch of the Windows registry. (LispWorks also offers a general Windows registry API, described in "Accessing the Windows registry" on page 468.)

On non-Windows the preferences are stored in subdirectories of the user's home directory.

To implement preferences for your LispWorks application, you will need to define a registry path using (`setf product-registry-path`) and read it using `product-registry-path`.

### 27.12.2 Accessing persistent settings

Get and set preferences under the product path at run time with `user-preference` and (`setf user-preference`).

### 27.12.3 Example using user preferences

Define a registry path:

```
(setf (sys:product-registry-path :deep-thought)
      ('("Software" "My Company" "Deep Thought")))
```

Store a preference for the current user:

```
(setf (user-preference "Answers"
                        "Ultimate Question"
                        :product :deep-thought)
      42)
```

Retrieve a preference for the current user, potentially in a subsequent session:

```
(user-preference "Answers" "Ultimate Question"
                :product :deep-thought)
```

## 27.13 File system interface

### 27.13.1 Fast access to files in a directory

`fast-directory-files` gives a faster way to access files than `directory`, especially in situations when you need to filter based on simple features such as size and access time, or filter based on the name in a more complex way than `directory` can.

Instead of creating a list of pathnames and returning it, `fast-directory-files` traverses the files and calls a callback function on each file with its name and an opaque handle, which is referred to as *fdf-handle*. From this handle, you can retrieve the size, last-access time and last-modify time, and query whether the file is a directory, whether it is a link (for platforms other than Windows), and whether it is writable. The implementation makes the access to the *fdf-handle* much faster than doing the same by calling `directory` and then calling `cl:file-write-date` and similar functions on the result.

When the callback returns non-nil, `fast-directory-files` collects the file-name, otherwise it ignores it. Hence the callback can be used both as a filter and to actually do some work. In many cases, the callback will always return nil, and the call will be used just to map the callback on the file for the "side-effects" of the callback.

`fast-directory-files` is restricted to one directory level, that is it cannot deal with wild directories.

## 27.14 Special locations in the file system

This section describes interfaces allowing you to identify and access various special locations in the file system.

### 27.14.1 The home directory

This section describes the implementation of the Common Lisp function `cl:user-homedir-pathname`.

On Unix-based systems, the home directory is looked up using the C function `getpwuid`.

On Microsoft Windows systems, `cl:user-homedir-pathname` uses the environment to construct its result. It uses the values of the environment variables HOMEDRIVE and HOMEPATH, if both are defined. If at least one of environment variables HOMEDRIVE and HOMEPATH is not defined, then a pathname `#P"C:/users/login-name"` is returned. These environment variables should be correctly set before LispWorks starts. However it is possible to change the values in Lisp using

```
(setf environment-variable)
```

On Android `cl:user-homedir-pathname` returns the result of calling `"android.os.Environment.getExternalStoragePublicDirectory"` with the value of `android.os.Environment.DIRECTORY_DOCUMENTS`.

### 27.14.2 Special Folders

On Microsoft Windows, Mac OS X and Android there are various special folders used for application data and user data. Here are some examples of the folder for application data which is shared between all users.

Windows 10, Windows 8, Windows 7 and Windows Vista

`C:\ProgramData`

Windows XP (now unsupported)

```
C:\Documents and Settings\All Users.WIN-
DOWS\Application Data
```

Mac OS X

```
/Library/Application Support
```

Android

The result of calling `getExternalFilesDir` on the application context with `null`.

The locations and folder names can differ between versions of the operating system, therefore it is useful to have a system-independent way to get the path at run time. The function `get-folder-path` can be used to retrieve the path to special folders. Directory pathnames corresponding to each of the examples above can be obtained by calling:

```
(sys:get-folder-path :common-appdata)
```

Here is another example of differences between operating systems. On Windows 7 and Windows Vista:

```
(sys:get-folder-path :my-documents)
=>
#P"C:/Users/dubya/Documents/"
```

On Mac OS X:

```
(sys:get-folder-path :my-documents)
=>
#P"/u/ldisk/dubya/Documents/"
```

See `get-folder-path` for more details.

On Microsoft Windows there is a profile folder for each user. You can find the profile path for the current user with the function `get-user-profile-directory`.

### 27.14.3 Temp files

A "temp file" is a file in the "temp directory" which is guaranteed to be new. Its name contains a random element.

Create a temp file by calling either of the functions `open-temp-file` and `create-temp-file`. For example:

On Microsoft Windows:

```
(create-temp-file :prefix "LW")
=>
#P"C:/DOCUME~1/dubya/LOCALS~1/Temp/LW383vwVfZN.tmp"
```

On Linux:

```
(create-temp-file :prefix "LW")
=>
#P"/tmp/LWladokNa.tmp"
```

The function `set-temp-directory` allows you to set the "temp directory", that is the default directory used for temp files.

## 27.15 Accessing the Windows registry

There is an API for accessing the registry on Microsoft Windows. It is available only in LispWorks for Windows. All of its symbols are in the `win32` package.

Create and delete keys with the functions `create-registry-key` and `delete-registry-key`. Open a key for reading and/or writing with `open-registry-key` and close it with `close-registry-key`, or wrap your registry operation inside the macro `with-registry-key`.

Query the registry with `registry-key-exists-p`, `enum-registry-value`, `collect-registry-values`, `collect-registry-subkeys`, `query-registry-key-info`, `query-registry-value`, and `registry-value`. Write to the registry with `set-registry-value` or `(setf registry-value)`.

For example, this function returns the name, progid and filename for each of the installed ActiveX controls:

```
(defun collect-control-names (&key insertable
                                (max-name-size 256)
                                (max-names most-positive-fixnum) )
  (win32:collect-registry-subkeys
   "CLSID"
   :root :root
   :max-name-size max-name-size
   :max-names max-names
   :value-function
   #'(lambda (hKeyClsid ClassidName)
       (win32:with-registry-key
        (hkeyX ClassidName :root hKeyClsid :errorp nil)
        (when (and
                (win32:registry-key-exists-p "Control"
                                              :root hkeyX)
                (if insertable
                    (win32:registry-key-exists-p "Insertable"
                                                  :root hkeyX)
                    t))
        (when-let
            (progid (win32:query-registry-value "ProgID" nil
                                                 :root hkeyX
                                                 :errorp nil))
            (values
             (list
              (win32:query-registry-value nil nil
                                         :root hkeyX)
              progid
              (win32:query-registry-value "InprocServer32" nil
                                         :root hkeyX
                                         :errorp nil)))
        t))))))
```

## 27.16 Pathname comparison on Mac OS X

Comparing pathnames using `equal` and `equalp` is case-sensitive on the Macintosh. This can lead to occasional unexpected mismatch of pathnames, because the HFS+ filesystem is usually case-insensitive (some Macintosh file systems are case-sensitive).

# 28

---

## Miscellaneous Utilities

This chapter describes miscellaneous functionality which does not belong in other chapters.

### 28.1 Object addresses and memory

In general, you cannot rely on the addresses of Lisp objects, because the Garbage Collector moves objects. The functions described in this section are intended for debugging only.

You can find the current address of a Lisp object as an integer by `object-address`. You can get the pointer of an object (current address plus any tagging) by `object-pointer`. This is what is normally used when printing objects unreadably. You can find which object is currently at some address by using `pointer-from-address`.

You can find the size of a heap object by using `find-object-size`. However, many Lisp objects are made of multiple heap objects, and typically the "root" heap object (the one that the Lisp pointer points to) is relatively small, so for these objects `find-object-size` returns a meaningless value. It is actually useful only for vectors that are simple (not with fill pointer or adjustable or displaced) and structures. It also gives meaningful values for integers, floats and conses.

## 28.2 Optimized integer arithmetic and integer vector access

This section describes ways to perform certain operations as efficiently as possible, including vector access and raw 32-bit arithmetic. Additionally in 64-bit LispWorks, raw 64-bit arithmetic is possible.

### 28.2.1 Typed aref vectors

You can make vectors of certain element types which allow the most efficient access possible when compiled with suitable optimize qualities.

To do this:

1. Make a vector with `make-typed-aref-vector`.
2. Access the vector using `typed-aref` and `(setf typed-aref)` with a `type` argument of `double-float`, `float`, `single-float`, `int32`, `(unsigned-byte n)` or `(signed-byte n)` where  $n = 8, 16$  or  $32$ .  
Additionally, in 64-bit LispWorks the types `(unsigned-byte 64)` and `(signed-byte 64)` are supported.
3. Compile the access with `safety 0` (and for float types, `float 0`) and a constant `type`.

See `typed-aref` for more details and examples.

Efficient access to foreign arrays is also available. See `fli:foreign-typed-aref` in the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

### 28.2.2 Fast 32-bit arithmetic

The INT32 API provides a way to perform optimal raw 32-bit arithmetic. Note that, unlike Lisp integer types, this is modulo  $2^{32}$  like the C `int` type.

The INT32 symbols are all in the `system` package.

The Lisp type `int32` reads 32 bits of memory, like `(signed-byte 32)`, but the data is in `int32` format for use with the INT32 API.

### 28.2.2.1 Optimized and unoptimized INT32 code

When optimized correctly, the intermediate `int32` objects are not constructed.

In unoptimized code, sequences of operations like

```
(sys:int32+ (sys:int32- a b) (sys:int32- c d))
```

will generate intermediate `int32` objects for the results of the subtraction, but the compiler can optimize these away because it knows that the function `int32+` consumes `int32` objects.

**Note:** the INT32 API is not designed to optimize `sys:int32` objects passed as arguments.

### 28.2.2.2 The INT32 API

The INT32 API contains the type `int32`, a vector type `simple-int32-vector` and accessor, functions to convert `int32` to and from integer, some constant `int32` values, and a full range of operators for mod  $2^{32}$  arithmetic.

You can find all these by evaluating

```
(apropos "INT32" "SYSTEM" t)
```

For details for each, see the entries starting with `int32` in Chapter 49, “The SYSTEM Package”.

### 28.2.2.3 INT32 Optimization

The optimization works safely but without boxing when possible. You need

```
(optimize (float 0))
```

to get the optimization. This `float` level affects whether INT32 operations are optimized. This declaration must be placed at the start of a function (not on an inner `let` or `locally` form).

In this example the `safety` level assures a second optimization in `fli:foreign-typed-aref`:

```
(defun incf-signed-byte-32 (ptr index)
  (declare (optimize (safety 0) (float 0))
           (type fixnum index))
  (setf (fli:foreign-typed-aref 'sys:int32 ptr index)
        (sys:int32-1+ (fli:foreign-typed-aref 'sys:int32
                                              ptr index)))
  ;; return ptr, since otherwise the int32 would
  ;; need to be boxed to return it
  ptr)
```

### 28.2.3 Fast 64-bit arithmetic

The INT64 API provides a way to perform optimal raw 64-bit arithmetic. Note that, unlike Lisp integer types, this is modulo  $2^{64}$  like the C `long long` or `int64` types.

The INT64 symbols are all in the `system` package.

The Lisp type `int64` reads 64 bits of memory, like `(signed-byte 64)`, but the data is in `int64` format for use with the INT64 API.

#### 28.2.3.1 Optimized and unoptimized INT64 code

When optimized correctly, the intermediate `int64` objects are not constructed.

In unoptimized code, sequences of operations like

```
(sys:int64+ (sys:int64- a b) (sys:int64- c d))
```

will generate intermediate `int64` objects for the results of the subtraction, but the compiler can optimize these away because it knows that the function `int64+` consumes `int64` objects.

**Note:** the INT64 API is not designed to optimize `sys:int64` objects passed as arguments.

#### 28.2.3.2 The INT64 API

The INT64 API contains the type `int64`, a vector type `simple-int64-vector` and accessor, functions to convert `int64` to and from integer, some constant `int64` values, and a full range of operators for mod  $2^{64}$  arithmetic.

You can find all these by evaluating

```
(apropos "INT64" "SYSTEM" t)
```

For details for each, see the entries starting with `int64` in Chapter 49, “The SYSTEM Package”.

### 28.2.3.3 INT64 Optimization

INT64 optimization occurs only in 64-bit LispWorks. The INT64 API is not optimized in 32-bit LispWorks.

The optimization works safely but without boxing when possible. You need

```
(optimize (float 0))
```

to get the optimization. This `float` level affects whether INT64 operations are optimized. This declaration must be placed at the start of a function (not on an inner `let` or `locally` form).

In this example the `safety` level assures a second optimization in `fli:foreign-typed-aref`:

```
(defun incf-signed-byte-64 (ptr index)
  (declare (optimize (safety 0) (float 0))
           (type fixnum index))
  (setf (fli:foreign-typed-aref 'sys:int64 ptr index)
        (sys:int64-1+ (fli:foreign-typed-aref 'sys:int64
                                              ptr index)))
  ;; return ptr, since otherwise the int64 would
  ;; need to be boxed to return it
  ptr)
```

### 28.2.4 Integer vector access

`octet-ref` and `base-char-ref` (and their setters) are provided to allow efficient access to simple vectors of element type (`unsigned-byte 8`) or `base-char` (that is, `simple-base-strings`) in the same code.

Other vector types are accepted, but for these specific string and binary vector types `octet-ref` and `base-char-ref` match what `aref` and `(setf aref)` do except that they always take and return the same value/result type, and they are also more efficient than `aref`.

Use `octet-ref` and `base-char-ref` according to whether you work with elements of type `integer` or `base-char`.

## 28.3 Transferring large amounts of data

You can write Lisp data in a binary format to a file using `dump-forms-to-file` or `with-output-to-fasl-file` with `dump-form`. The file can then be loaded by `load-data-file`.

This allows you to transfer large amounts of data without using the Lisp printer and reader, which is much more efficient and robust.

## 28.4 Rings

Ring objects can be used to hold Lisp objects (elements) and provide stack-like behavior. Each ring is limited to a maximum number of elements and can be rotated. You can control the insertion point where elements get added and removed, and iterate across the elements.

For more information about rings, start at `make-ring`.

## 28.5 Conditional throw and checking for catch in the dynamic environment

In some situations it may be useful to check whether there is a specific catch in the dynamic scope, and throw if there is such a catch. The function `find-throw-tag` and the macro `throw-if-tag-found` can be used in these circumstances.

## 28.6 Checking for a dynamic binding

Use `symbol-dynamically-bound-p` to test whether a symbol is dynamically bound in the current environment.

# 29

---

## 64-bit LispWorks

This chapter summarizes the technical differences between 64-bit LispWorks and 32-bit LispWorks. Both are ANSI Common Lisp implementations and support the same language extensions and libraries, so in many ways they behave the same. However the programmer should be aware of the differences mentioned here.

### 29.1 Introduction

64-bit LispWorks has a larger address space, subject to physical memory. The maximum heap sizes are shown in Table 29.1.

You can make larger arrays and the `fixnum` type is much larger than in 32-bit LispWorks. The values of various Common Lisp architectural constants reflect this, as shown in Table 29.2.

Other differences in 64-bit LispWorks are noted in the remaining sections of this chapter.

## 29.2 Heap size

In principle 64-bit LispWorks can grow to almost 16 TB but it is intentionally limited to a defined range in order to avoid clashes with other software as shown in Table 29.1.

Table 29.1 Default range for 64-bit LispWorks heap

Platform	Default range	Notes
Intel-based Macintosh	#x4000000000 to #x4000000000 (3.75 TB)	
PowerPC Macintosh	#x4000000000 to #x4000000000 (3.75 TB)	
old Linux	#x4000000000 to #x7000000000 (192 GB)	Effective limit around 160 GB.
modern Linux	#x4000000000 to #x4400000000 (4 TB)	
Windows	#x4000000000 to #x4000000000 (3.75 TB)	
Solaris	#x4000000000 to #x100000000000 (768 GB)	

In contrast, 32-bit LispWorks has a maximum heap size of 1.5-3.0 GB depending on platform.

Normally 64-bit LispWorks for Linux automatically adjusts its default heap size on startup according to whether it runs on "old Linux" or "new Linux". On old systems, LispWorks sets the end of its range to `x7000000000`. On new systems, it sets the end to `#x4400000000`, thus giving a range of 4 TB. However, if the size is given explicitly by command line argument `--reserve-size` or `InitLispWorks` in a dynamic library, then this overrides the automatic adjustment.

LispWorks is relocatable on all supported platforms as described in "Startup relocation of 32-bit LispWorks" on page 460 and "Startup relocation of 64-bit LispWorks" on page 461.

## 29.3 Architectural constants

Common Lisp constants have the values shown in Table 29.2

Table 29.2 Architectural constants

Constant	32-bit LispWorks	64-bit LispWorks
<code>most-positive-fixnum</code>	$2^{29} - 1$	$2^{60} - 1$
<code>array-dimension-limit</code>	67108337 (almost $2^{26}$ )	$2^{29} - 1$
<code>array-total-size-limit</code>	$2^{26}$	$2^{29} - 1$

**Note:** In 32-bit LispWorks 5.0, `array-total-size-limit` is  $2^{29} - 1$ , which is wrong.

## 29.4 Speed

64-bit LispWorks is generally faster than 32-bit LispWorks.

We would be interested to see comparative performance data from your application if it runs on both 32-bit and 64-bit LispWorks.

## 29.5 Memory Management and cl:room

Memory layout and the garbage collector (GC) differ significantly between the two implementations.

For the details see “Memory Management in 32-bit LispWorks” on page 135 and “Memory Management in 64-bit LispWorks” on page 146.

The output of `room` differs between 64-bit and 32-bit LispWorks.

## 29.6 Greater allocation expected in 64-bit LispWorks

In 64-bit LispWorks pointers are 8 bytes, whereas in 32-bit LispWorks pointers are 4 bytes. Since many objects contain pointers, most programs will allocate more in 64-bit LispWorks, typically at least 50% or more.

A program containing mostly strings would not show this difference, since strings are more comparable in size between the two implementations.

You can use `find-object-size` to find the size of an object.

## 29.7 Float types

In 64-bit LispWorks `single-floats` are immediate objects, and `short-float` is the same type as `single-float`.

In 32-bit LispWorks `single-floats` are boxed objects, and `short-float` is disjoint from other float types.

## 29.8 External libraries

Third party libraries loaded into 64-bit LispWorks must be 64-bit. Availability of a suitable library is therefore a possible issue when porting your LispWorks application to 64-bit.

Third party libraries loaded into 32-bit LispWorks must be 32-bit.

# 30

---

## Self-contained examples

This chapter enumerates the set of examples in the LispWorks library relevant to the content of this manual. Each example file contains complete, self-contained code and detailed comments, which include one or more entry points near the start of the file which you can run to start the program.

To run the example code:

1. Open the file in the Editor tool in the LispWorks IDE. Evaluating the call to `example-edit-file` shown below will achieve this.
2. Compile the example code, by `Ctrl+Shift+B`.
3. Place the cursor at the end of the entry point form and press `Ctrl+X Ctrl+E` to run it.
4. Read the comment at the top of the file, which may contain further instructions on how to interact with the example.

### 30.1 COMM examples

#### 30.1.1 SSL examples

This section lists the example files illustrating the use of SSL in socket streams, described in detail in “Using SSL” on page 418:

```
(example-edit-file "ssl/ssl-server")
(example-edit-file "ssl/ssl-client")
(example-edit-file "ssl/ssl-certificates")
```

### 30.1.2 Asynchronous I/O examples

This section lists the example files illustrating the Asynchronous I/O API, described in detail in “Asynchronous I/O” on page 411:

```
(example-edit-file "async-io/driver")
(example-edit-file "async-io/multiplication-table")
(example-edit-file "async-io/print-connection-delay")
(example-edit-file "ssl/async-io-client")
(example-edit-file "async-io/udp")
```

## 30.2 Streams examples

```
(example-edit-file "streams/buffered-stream")
```

## 30.3 DDE examples

This section lists the example files illustrating Dynamic Data Exchange (DDE) on Microsoft Windows, described in detail in “Dynamic Data Exchange” on page 321:

```
(example-edit-file "dde/lispworks-ide")
(example-edit-file "dde/server-dispatching")
(example-edit-file "dde/server-dispatching-client")
```

## 30.4 Parser generator examples

```
(example-edit-file "parser-generator/expression-parser")
```

## 30.5 Examples for save-image in a Mac OS X application

## bundle

This section lists the example files illustrating how you can create an application bundle while saving an image on Mac OS X. See “Saving a LispWorks image” on page 179 for details of the process:

```
(example-edit-file "configuration/macos-application-bundle")
(example-edit-file "configuration/save-macos-application")
```

**Note:** These examples are provided as a starting point for programmers who need to modify their own bundle-creation code. LispWorks for Macintosh has documented functions `create-macos-application-bundle` and `save-image-with-bundle` which you should use unless you need different functionality.

## 30.6 Miscellaneous examples

A minimal example of parsing XML:

```
(example-edit-file "misc/xml-parser")
```

Code for using ASDF in the LispWorks IDE, described in more detail in “Using ASDF” on page 311:

```
(example-edit-file "misc/asdf-integration")
```

# 31

---

## The CLOS Package

This chapter describes the LispWorks extensions to CLOS, the Common Lisp Object System.

The LispWorks Meta Object Protocol mostly conforms to chapters 5 & 6 of AMOP. Manual pages for symbols with different functionality from AMOP are in this chapter, and the differences are discussed in Chapter 18, “The Metaobject Protocol”.

		<i>Function</i>
Summary		Breaks to the debugger when a new instance of a class is accessed. Note that this function is deprecated.
Package		<code>clos</code>
Signature		<code>break-new-instances-on-access <i>class-designator</i> &amp;key <i>read</i> <i>write</i> <i>slot-names</i> <i>when</i> <i>process</i> <i>trace-output</i> <i>entrycond</i> <i>eval-before</i> <i>before</i> <i>backtrace</i> =&gt; <i>t</i></code>
Arguments		<i>class-designator</i> The class to trap.
Values		Returns <i>t</i> .

Description	Causes a break when new instances of the class given by <i>class-designator</i> are accessed, according to the keyword arguments.
	The keyword arguments control which type of access cause a break and are interpreted as described for <code>trace-on-access</code> .
	<b>Note:</b> this function is deprecated. You should now call <code>trace-new-instances-on-access</code> with <code>:break t</code> instead.
See also	<code>trace-new-instances-on-access</code>

	<i>Function</i>
<b>break-on-access</b>	
Summary	Breaks to the debugger when an instance of a class is accessed. Note that this function is deprecated.
Package	<code>clos</code>
Signature	<code>break-on-access instance &amp;key read write slot-names when process trace-output entrycond eval-before before backtrace =&gt; t</code>
Arguments	<code>instance</code> A CLOS instance.
Values	Returns <code>t</code> .
Description	A useful debugging function which causes access to <i>instance</i> to break to the debugger. Accesses include calls to <code>slot-value</code> and also accessor functions defined by the class of <i>instance</i> . Other instances of the same class are unaffected.  The keyword arguments control which type of access cause a break and are interpreted as described for <code>trace-on-access</code> .  You can remove the break by calling <code>unbreak-on-access</code> .  A common use of this function is to find where a slot is being changed in a complex program.

**Note:** this function is deprecated. You should now call `trace-on-access` with `:break t` instead.

See also [trace-on-access](#)

## class-extra-initargs

## *Generic Function*

Summary	Extends the valid initialization arguments of a class.	
Package	clos	
Signature	<code>class-extra-initargs prototype =&gt; initargs</code>	
Arguments	<code>prototype</code>	A class prototype.
Values	<code>initargs</code>	A list of additional initialization arguments.
Description	<p>The generic function <code>class-extra-initargs</code> lets you extend the set of valid initialization arguments for a class and its subclasses. <code>initargs</code> should be a list of symbols. Each symbol becomes a valid initarg for the class. By default in a non-delivered LispWorks image, <code>make-instance</code> and other CLOS initializations (see <code>set-clos-initarg-checking</code>) check that initargs passed to them are valid.</p> <p>The extra initargs are used for <code>make-instance</code>, <code>reinitialize-instance</code>, <code>update-instance-for-redefined-class</code> and <code>update-instance-for-different-class</code>.</p>	
Notes	<p><code>class-extra-initargs</code> is useful only in complex cases. In most cases other ways of extending the set of valid initargs are simpler and clearer, such as the <code>:extra-initargs</code> class option, described in <code>defclass</code>.</p>	
Example	<p>In this session an illegal initarg <code>:my-keyword</code> is passed, causing <code>make-instance</code> to signal an error.</p>	

Then `:my-keyword` is added as an extra initarg, after which `make-instance` accepts it.

```
CL-USER 38 > (defclass my-class () ((a :initform nil)))
#<STANDARD-CLASS MY-CLASS 113AAA2F>

CL-USER 39 > (make-instance 'my-class :my-keyword 8)

Error: MAKE-INSTANCE is called with unknown keyword
:MY-KEYWORD among the arguments (MY-CLASS :MY-KEYWORD
8) {no keywords allowed}
  1 (continue) Ignore the keyword :MY-KEYWORD
  2 (abort) Return to level 0.
  3 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 40 : 1 > :a

CL-USER 41 > (defmethod clos:class-extra-initargs

## compute-class-potential-initargs

## Generic Function

Summary      Computes the valid initargs of a class.

Package      `clos`

Signature      `compute-class-potential-initargs class => initargs`

Arguments	<i>class</i>	A class.
Values	<i>initargs</i>	A list of symbols, or <code>t</code> .
Description	<p>The generic function <code>compute-class-potential-initargs</code> is called to compute the initialization arguments of a class. This set of valid initargs is used by <code>make-instance</code> when its arguments are checked.</p> <p><i>class</i> is the class passed to <code>make-instance</code>. That is, <code>compute-class-potential-initargs</code> specializes on the metaclass.</p> <p><i>initargs</i> is either a list of valid initargs, or <code>t</code> meaning that any initialization argument is allowed.</p> <p>There is a supplied method on <code>t</code>, which returns <code>nil</code>.</p> <p>The other supplied method is on <code>standard-class</code>. This consults the Relevant Methods, which are the applicable methods of <code>make-instance</code>, <code>allocate-instance</code>, <code>initialize-instance</code> and <code>shared-initialize</code>. If any of the Relevant Methods have a lambda list containing <code>&amp;allow-other-keys</code> then <i>initargs</i> is <code>t</code>. Otherwise <i>initargs</i> is a list containing:</p> <ul style="list-style-type: none"> <li>• all the <code>&amp;key</code> arguments from Relevant Method lambda lists, and</li> <li>• the initargs of the slots of <i>class</i> and its superclasses, and</li> <li>• any extra initargs specified via the class option <code>:extra-initargs</code> (see <code>defclass</code> for details of this), and</li> <li>• any extra initargs returned by <code>class-extra-initargs</code>.</li> </ul> <p>The list <i>initargs</i> contains no duplicates, and the result of <code>compute-class-potential-initargs</code> is cached so that it is not recomputed unless one of the Relevant Methods, the class or its class precedence list is altered.</p>	

See also      `class-extra-initargs`  
`make-instance`  
`set-clos-initarg-checking`

## **compute-discriminating-function**                          *Generic Function*

Summary      Returns the discriminating function.

Package      `clos`

Signature      `compute-discriminating-function gf => result`

Arguments      `gf`                          A generic function.

Values      `result`                          A function.

Description      The generic function `compute-discriminating-function` returns the discriminator as specified in AMOP.

However, there are two discrepancies with the AMOP behavior:

- The discriminating function does not `compute-applicable-methods-using-classes`, since this is not implemented.
- `add-method` does not call `compute-discriminating-function`. Instead, it is called when the generic function is called. This is more efficient than calling `compute-discriminating-function` each time `add-method` is called.

## **compute-effective-method-function-from-classes**                          *Generic Function*

Summary      Returns the effective method function.

Package      `clos`

Signature	<code>compute-effective-method-function-from-classes gf classes =&gt; em-function</code>	
Arguments	<i>gf</i>	A generic function.
	<i>classes</i>	A list of class metaobjects.
Values	<i>em-function</i>	A function or <code>nil</code> .
Description	<p>The generic function <code>compute-effective-method-function-from-classes</code> is called by LispWorks to compute the effective method function when <i>gf</i> is called with required argument types specified by <i>classes</i>. If <i>em-function</i> is <code>nil</code>, then <code>no-applicable-method</code> is called. Otherwise, <i>em-function</i> may be cached by the generic function and is called with the arguments supplied to the generic function.</p> <p>The default method for <code>compute-effective-method-function-from-classes</code> implements the standard generic function behavior of finding the applicable methods and using the method combination to construct a function that calls them.</p> <p>In order for <code>compute-effective-method-function-from-classes</code> to be called and the result cached, there must be methods specializing on the "interesting" arguments. For the standard behavior, this is trivially true, but if you want to implement other behavior then you need to define dummy methods even if they are never called.</p>	
Example	<p>A "computed" generic function that returns a value based on a form chosen from the classes of the arguments rather than the methods. Note the dummy method which is specialized on null.</p>	

```

(defclass computed-generic-function (standard-generic-
function)
  ((computer :initarg :computer
             :accessor computed-generic-function-
computer))
  (:metaclass funcallable-standard-class))

(defmethod clos:compute-effective-method-function-from-
classes
  ((gf computed-generic-function)
   classes)
  (apply (computed-generic-function-computer gf) gf
classes))

(defmacro define-computed-generic-function (name
lambda-list

specializers
                           &body body)
  `(dspec:def (define-computed-generic-function ,name)
     (defgeneric ,name ,lambda-list
       (:generic-function-class computed-generic-
function)
       (:method ,(loop for arg in lambda-list
                      collect
                      (if (member arg specializers)
                          `,(arg null)
                          arg))))
     (setf (computed-generic-function-computer #' ,name)
           #'(lambda (,name ,@(loop for arg in lambda-
list
                           collect
                           (if (member arg
specializers)
                               arg
                               (gensym)))) ,@body))
          ',name))

(define-computed-generic-function aaaa (x y) (x)
  (let ((something (compute-something aaaa x)))
    #'(lambda (x y)
        (declare (ignore y))
        (format nil "Something for ~a is ~a" x
something)))

(defun compute-something (gf class)

```

```
(format nil "~a--a"
        (generic-function-name gf)
        (class-name class)))
```

## copy-standard-object

*Function*

Summary	Creates a new copy of a CLOS object.	
Package	<code>clos</code>	
Signature	<code>copy-standard-object source =&gt; target</code>	
Arguments	<code>source</code> A <b>standard-object</b> , but not a <b>funcallable-standard-object</b> .	
Values	<code>target</code> A <b>standard-object</b> , but not a <b>funcallable-standard-object</b> .	
Description	<p>The function <code>copy-standard-object</code> creates a new copy of the CLOS object <code>source</code>. <code>source</code> must be of type <b>standard-object</b>, excluding <b>funcallable-standard-object</b> and its subclasses, in particular it cannot be of type <b>generic-function</b>. The copying is shallow, that is only the actual values are copied, as if by</p>	

```
(dolist (slot instance-slots)
        (setf (slot-value target slot)
              (slot-value source slot)))
```

assuming no definition that affects what `slot-value` and `(setf slot-value)` do. However, `copy-standard-object` bypasses the `slot-value` mechanism and is much faster.

`copy-standard-object` should be used on instances of user-defined classes which do not inherit from system-defined

classes (other than `standard-object`). If *source* is an instance of a system-defined class (or a subclass of a system-defined class) then *target* cannot be used as a functional object, but its slot values can be read safely. That may be useful for debugging.

See also      `replace-standard-object`

## `funcallable-standard-object` *Class*

Package      `clos`

Superclasses    `function`  
`standard-object`

Subclasses     `generic-function`

Description     The metaclass `funcallable-standard-object` provides the default `:direct-superclasses` for instances of `funcallable-standard-class` and its subclasses.

`funcallable-standard-object` is implemented as described in AMOP except for a different order in the class precedence list.

In AMOP the class precedence list is

```
(funcallable-standard-object standard-object
function t)
```

whereas in LispWorks the class precedence list is

```
(funcallable-standard-object function
standard-object t)
```

LispWorks is like this to be compliant with the rules in the ANSI Common Lisp Standard.

The AMOP class precedence list implies a class precedence for `generic-function` which violates the last sentence in

ANSI Common Lisp 4.2.2 Type Relationships. See [www.lisp-works.com/reference/HyperSpec/Body/04\\_bb.htm](http://www.lisp-works.com/reference/HyperSpec/Body/04_bb.htm).

## process-a-class-option

### *Generic Function*

Summary	Describes how the value of a class option is parsed.	
Package	<code>clos</code>	
Signature	<code>process-a-class-option metaclass option value =&gt; initargs</code>	
Arguments	<code>metaclass</code>	The metaclass of the class being parsed.
	<code>option</code>	The <code>defclass</code> option name.
	<code>value</code>	The tail of the <code>defclass</code> option form.
Values	<code>initargs</code>	A plist of initargs describing the option.
Description	<p>The generic function <code>process-a-class-option</code> describes how the value of a class option is parsed. It is called at <code>defclass</code> macroexpansion time. By default LispWorks parses class options as defined in AMOP, but you need to supply a method if you need class options with different behavior.</p> <p><code>initargs</code> should be a plist of class initargs and values. These are added to any other initargs for the class.</p>	
Example	<pre>(defclass m1 (standard-class)   ((title :initarg :title)))</pre>	
	For single-valued, evaluated title option, add a method like this:	

```
(defmethod clos:process-a-class-option
  ((class m1)
   (name (eql :title))
   value)
  (unless (and value (null (cdr value)))
    (error "m1 :title must have a single value."))
  (list name (car value)))

(defclass my-titled-class ()
  ()
  (:metaclass m1)
  (:title "Initial Title"))
```

If the value is not to be evaluated, the method would look like this:

```
(defmethod clos:process-a-class-option
  ((class m1)
   (name (eql :title))
   value)
  (unless (and value (null (cdr value)))
    (error "m1 :title must have a single value."))
  `,(name ',value))
```

Now suppose we want an option whose value is a list of titles:

```
(defclass m2 (standard-class)
  ((titles-list :initarg :list-of-possible-titles)))
```

If the titles are to be evaluated, add a method like this:

```
(defmethod clos:process-a-class-option
  ((class m2)
   (name (eql :list-of-possible-titles))
   value)
  (list name `(list ,@value)))
```

Or, if the titles should not be evaluated, add a method like this:

```

(defmethod clos:process-a-class-option
  ((class m2)
   (name (eql :list-of-possible-titles))
   value)
  (list name `',value))

(defclass my-multi-titled-class ()
  ()
  (:metaclass m2)
  (:list-of-possible-titles
   "Initial Title 1"
   "Initial Title 2"))

```

See also      **defclass**  
**process-a-slot-option**

## process-a-slot-option

## *Generic Function*

Summary      Describes how a **defclass** slot option is parsed.

Package      **clos**

Signature      **process-a-slot-option metaclass option value already-processed-other-options slot => processed-options**

Arguments      *metaclass*      The metaclass of the class being parsed.

*option*      The slot option name.

*value*      The value of the slot option.

*already-processed-other-options*

                A plist of initargs for non-standard options  
that have been processed already.

*slot*      The whole slot description.

Values      *processed-options*

                A plist of initargs.

Description	<p>The generic function <code>process-a-slot-option</code> describes how the value of a slot option is parsed. It is called at <code>defclass</code> macroexpansion time. By default LispWorks parses slot options as defined in AMOP, but you need to supply a method if you need slot options with different behavior.</p> <p><i>processed-options</i> should be a plist of slot initargs and values containing those from <i>already-processed-other-options</i> together with initargs for <i>option</i> as required. These are added to any other initargs for the slot.</p>
-------------	---

Example	<pre>(defclass extended-class (standard-class) ())  (defmethod clos:process-a-slot-option     ((class extended-class) option value      already-processed-options slot)   (if (eq option :extended-slot)       (list* :extended-slot              value              already-processed-options)       (call-next-method)))  (defclass extended-direct-slot-definition     (clos:standard-direct-slot-definition)   ((extended-slot :initarg :extended-slot :initform     nil)))  (defmethod clos:direct-slot-definition-class     ((x extended-class) &amp;rest initargs)   'extended-direct-slot-definition)  (defclass test ()   ((regular :initform 3)    (extended :extended-slot t :initform 4))   (:metaclass extended-class))</pre>
---------	--

To add a slot option `:special-reader` whose value is a non-evaluated symbol naming a reader:

```
(defmethod clos:process-a-slot-option
  ((class my-metaclass) option value
   already-processed-options slot)
  (if (and (eq option :special-reader)
            (symbolp value))
      (list* :special-reader
             `',(value already-processed-options)
             (call-next-method)))
  )
```

To allow repeated :special-reader options which are combined into a list:

```
(defmethod clos:process-a-slot-option
  ((class my-metaclass) option value
   already-processed-options slot)
  (if (and (eq option :special-reader) (symbolp value))
      (let ((existing (getf
                       already-processed-options
                       :special-reader)))
        (if existing ; this is a quoted list of symbols
            (progn
              (setf (cdr (last (cadr existing))) (list
value)))
              already-processed-options)
            (list* :special-reader
                   `'(),value)
                   already-processed-options)))
      (call-next-method)))
  )
```

See also      **defclass**  
**process-a-class-option**

## replace-standard-object *Function*

Summary      Replaces the values in a CLOS object's slots by the values of slots from another object.

Package      **clos**

Signature      **replace-standard-object target source => target**

Arguments	<i>source, target</i>	A <b>standard-object</b> , but not a <b>funcallable-standard-object</b> .
Description		<p>The function <b>replace-standard-object</b> replaces the values in the slots of the CLOS object <i>target</i> by the values of slots from the CLOS object <i>source</i>.</p> <p>Only slots with allocation type <b>:instance</b> are copied from <i>source</i> to <i>target</i>.</p> <p><i>source</i> and <i>target</i> must be of type <b>standard-object</b>, excluding <b>funcallable-standard-object</b> and its subclasses, in particular they cannot be of type <b>generic-function</b>. Moreover both must be of the same class, that is:</p> <pre>(eq (class-of target) (class-of source)) =&gt; t</pre> <p>The replacement is shallow, that is only the actual values are copied, as if by</p> <pre>(dolist (slot instance-slots)   (setf (slot-value target slot)         (slot-value source slot)))</pre> <p>assuming no definition that affects what <b>slot-value</b> and <b>(setf slot-value)</b> do. However, <b>replace-standard-object</b> bypasses the <b>slot-value</b> mechanism and is much faster.</p> <p><b>replace-standard-object</b> should be used on instances of user-defined classes which do not inherit from system-defined classes (other than <b>standard-object</b>). It should never be used on instances of system-defined classes and their subclasses.</p>
See also		<b>copy-standard-object</b>

	<i>Function</i>
Summary	Switches initarg checking on or off in <code>make-instance</code> , <code>reinitialize-instance</code> , <code>change-class</code> and so on.
Package	<code>clos</code>
Signature	<code>set-clos-initarg-checking on =&gt; on</code>
Arguments	<code>on</code> A generalized boolean.
Description	<p>The function <code>set-clos-initarg-checking</code> provides control over whether CLOS checks initialization arguments.</p> <p>Initializations affected include:</p> <ul style="list-style-type: none"> <li>• Calls to <code>make-instance</code></li> <li>• Calls to <code>reinitialize-instance</code></li> <li>• Calls to <code>change-class</code></li> <li>• <code>call-next-method</code> to <code>update-instance-for-redefined-class</code> with extra keywords.</li> </ul> <p>Calling <code>set-clos-initarg-checking</code> with a true value of <code>on</code> causes the above initializations to check their initargs. This is the initial state of LispWorks.</p> <p>Initarg checking is switched off globally and dynamically by</p> <pre>(set-clos-initarg-checking nil)</pre>
Notes	<ol style="list-style-type: none"> <li>1. The effect of calling <code>set-clos-initarg-checking</code> can be overridden in a runtime by the <code>deliver</code> keyword argument <code>:clos-initarg-checking</code>. See the <i>LispWorks Delivery User Guide</i> for details.</li> <li>2. <code>set-clos-initarg-checking</code> supersedes <code>set-make-instance-argument-checking</code>.</li> </ol>
See also	<code>class-extra-initargs</code> <code>compute-class-potential-initargs</code>

```
deliver
make-instance
```

## **set-make-instance-argument-checking** *Function*

Summary	Switches CLOS initarg checking on or off. This function is deprecated.	
Package	<b>clos</b>	
Signature	<b>set-make-instance-initarg-checking</b> <i>on</i> => <i>on</i>	
Arguments	<i>on</i>	A boolean.
Description	The deprecated function <b>set-make-instance-initarg-checking</b> switches CLOS initarg checking on or off.	
Notes	<b>set-make-instance-initarg-checking</b> is deprecated. It is an alias for <b>set-clos-initarg-checking</b> .	
Compatibility notes	<ol style="list-style-type: none"> <li>1. In LispWorks 6.1 and later versions <b>set-make-instance-initarg-checking</b> affects CLOS initializations other than <b>make-instance</b>. For clarity, you should now use <b>set-clos-initarg-checking</b> instead.</li> <li>2. In LispWorks 6.0 <b>set-make-instance-initarg-checking</b> affects only <b>make-instance</b>.</li> </ol>	
See also	<b>set-clos-initarg-checking</b>	

## **slot-boundp-using-class** *Generic Function*

Summary	Implements <b>slot-boundp</b> .
Package	<b>clos</b>

Signature	<code>slot-boundp-using-class <i>class object slot-name</i> =&gt; <i>result</i></code>	
Arguments	<i>class</i>	A class metaobject, the class of <i>object</i> .
	<i>object</i>	An object.
	<i>slot-name</i>	A slot name.
Values	<i>result</i>	A boolean.
Description	<p>The generic function <code>slot-boundp-using-class</code> implements the behavior of the <code>slot-boundp</code> function.</p> <p>The implementation is as described in AMOP, except that the third argument is the slot name, and not a slot definition metaobject. The primary methods specialize on <code>t</code> for this argument.</p>	
See also	<a href="#"><code>slot-makunbound-using-class</code></a> <a href="#"><code>slot-value-using-class</code></a>	

## **slot-makunbound-using-class** *Generic Function*

Summary	Implements <code>slot-makunbound</code> .	
Package	<code>clos</code>	
Signature	<code>slot-makunbound-using-class <i>class object slot-name</i> =&gt; <i>object</i></code>	
Arguments	<i>class</i>	A class metaobject, the class of <i>object</i> .
	<i>object</i>	An object.
	<i>slot-name</i>	A slot name.
Values	<i>object</i>	The <i>object</i> argument.
Description	<p>The generic function <code>slot-makunbound-using-class</code> implements the behavior of the <code>slot-makunbound</code> function.</p>	

The implementation is as described in AMOP, except that the third argument is the slot name, and not a slot definition metaobject. The primary methods specialize on `t` for this argument.

See also      `slot-boundp-using-class`  
                  `slot-value-using-class`

## **slot-value-using-class** *Generic Function*

Summary	Implements <code>slot-value</code> .	
Package	<code>clos</code>	
Signature	<code>slot-value-using-class class object slot-name =&gt; value</code> <code>(setf slot-value-using-class) value class object slot-name</code> <code>=&gt; value</code>	
Arguments	<code>class</code>	A class metaobject, the class of <i>object</i> .
	<code>object</code>	An object.
	<code>slot-name</code>	A slot name.
Values	<code>value</code>	The value of the slot named by <i>slot-name</i> .
Description	<p>The generic function <code>slot-value-using-class</code> implements the behavior of the <code>slot-value</code> function.</p> <p>The implementation is as described in AMOP, except that the third argument is the slot name, and not a slot definition metaobject. The primary methods specialize on <code>t</code> for this argument.</p> <p><b>Note:</b> by default, standard slot accessors are optimized to not call <code>slot-value-using-class</code>. This can be overridden with the <code>:optimize-slot-access</code> class option. See <code>defclass</code> for details.</p>

`slot-boundp-using-class`  
`slot-makunbound-using-class`

## trace-new-instances-on-access *Function*

Summary Traces new instances of a given class, based on access modes.

Package `clos`

Signature `trace-new-instances-on-access class-designator`  
`&key read write slot-names break when process trace-output`  
`entrycond eval-before before backtrace => t`

Arguments `class-designator` The class to trace.

Values Returns `t`.

Description Causes new instances of the class given by `class-designator` to be traced for the access modes given by `read`, `write` and `slot-names`.

The keyword arguments control which type of access are traced, and provide preconditions for tracing, code to run before access, and how to print any trace output. They are interpreted as described for `trace-on-access`.

This function, when used with the `:break` keyword, replaces the deprecated function `break-new-instances-on-access`.

Example `(trace-new-instances-on-access 'capi:display-pane :slot-names nil)`

Suppose you have a bug whereby the slot `bar` of an instance of your class `foo` is incorrectly being set to a negative integer value. You could cause entry into the debugger at the point where the slot is set incorrectly by evaluating this form:

```
(clos:trace-new-instances-on-access
  'foo
  :slot-names '(bar)
  :read nil
  :when '(and (integerp (car *traced-arglist*))
              (< (car *traced-arglist*) 0)))
  :break t)
```

and running your program.

**break-new-instances-on-access**  
**untrace-new-instances-on-access**  
**trace-on-access**

## trace-on-access *Function*

Summary	Invokes the trace facilities when an instance of a class is accessed.	
Package	clos	
Signature	<b>trace-on-access</b> <i>instance</i> & <b>key</b> <i>read</i> <i>write</i> <i>slot-names</i> <i>break</i> <i>when</i> <i>process</i> <i>trace-output</i> <i>entrycond</i> <i>eval-before</i> <i>before</i> <i>backtrace</i> => <i>t</i>	
Arguments	<i>instance</i>	A CLOS instance.
	<i>read</i>	A generalized boolean.
	<i>write</i>	A generalized boolean.
	<i>slot-names</i>	A list of symbols, or t.
	<i>break</i>	A generalized boolean.
	<i>when</i>	A form.
	<i>process</i>	A form.
	<i>trace-output</i>	A form.
	<i>entrycond</i>	A form.
	<i>eval-before</i>	A list of forms.

<i>before</i>	A list of forms.
<i>backtrace</i>	A keyword, <code>t</code> or <code>nil</code> .
Values	Returns <code>t</code> .
Description	<p>A useful debugging function which causes access to <i>instance</i> to invoke the trace facilities. Accesses include calls to <code>slot-value</code> and accessor functions defined by the class of <i>instance</i>.</p> <p>The keyword arguments control which type of access are traced, and provide preconditions for tracing, code to run before access, and how to print any trace output. They are similar to those supported by the <code>trace</code> macro (but note that these CLOS symbols are functions, so the keyword values are evaluated immediately, unlike in <code>trace</code>).</p> <p><i>read</i> controls whether reading slots is traced. The default is <code>t</code>.</p> <p><i>write</i> controls whether writing slots is traced. The default is <code>t</code>.</p> <p><i>slot-names</i> controls which slots to trace access for. It can be a list of symbols which are the slot-names. The default value, <code>t</code>, means trace access to all slots.</p> <p><i>break</i> controls whether the debugger is entered when a traced slot in <i>instance</i> is accessed. When <code>nil</code>, the debugger is not invoked and messages are printed to <code>*trace-output*</code>. The default value is <code>nil</code>.</p> <p><i>when</i> is evaluated during slot access to determine whether any tracing should occur. The default value is <code>t</code>.</p> <p><i>process</i> is evaluated during slot access to determine whether any tracing should occur in the current process. The form should evaluate to either <code>nil</code> (meaning trace in all processes), a string naming the process in which tracing should occur (see <code>process-name</code>, <code>find-process-from-name</code>), or a list of strings naming the processes in which tracing should occur. The default value is <code>nil</code>.</p>

*trace-output* is evaluated during slot access to determine the stream on which to print tracing messages. If this is `nil` then the value of `*trace-output*` is used. The default value is `nil`.

*entrycond* is evaluated during slot access to determine whether the default tracing messages should be printed.

*eval-before* is a list of forms which are evaluated during slot access.

*before* is a list of forms which are evaluated during slot access. The first value returned by each form is printed.

*backtrace* controls what kind of backtrace to print. If this is `nil` then no backtrace is printed, and this is the default value. Otherwise it can be any of the following values:

- `:quick` Like the `:bq` debugger command.
- `t` Like the `:b` debugger command.
- `:verbose` Like the `:b :verbose` debugger command.
- `:bug-form` Like the `:bug-form` debugger command.

Other instances of the same class are unaffected and you can remove the trace by calling `untrace-on-access`.

The variable `*traced-arglist*` is bound to a list of arguments for the slot access during evaluation of the options above, that is (*instance slot-name*) when reading a slot and (*new-value instance slot-name*) when writing a slot.

A common use of this function is to find where a slot is being changed in a complex program.

This function, when called with `:break t`, replaces the deprecated function `break-on-access`.

`break-on-access`

## **unbreak-new-instances-on-access** *Function*

Summary	Removes the trapping installed by <code>break-new-instances-on-access</code> . Note that this function is deprecated.
Package	<code>clos</code>
Signature	<code>unbreak-new-instances-on-access class-designator =&gt; t</code>
Arguments	<code>class-designator</code> The class whose trap you want to remove.
Values	Returns <code>t</code> .
Description	Removes the trapping installed by <code>break-new-instances-on-access</code> . Note that this function is deprecated. You should now use <code>untrace-new-instances-on-access</code> instead.
See also	<code>untrace-new-instances-on-access</code>

## **unbreak-on-access** *Function*

Summary	Removes the trapping installed by <code>break-on-access</code> . Note that this function is deprecated.
Package	<code>clos</code>
Signature	<code>unbreak-on-access instance</code>
Arguments	<code>instance</code> A class instance
Values	Returns <code>t</code> .
Description	Removes any break installed on <code>instance</code> by <code>break-on-access</code> . See <code>untrace-on-access</code> for details.
	<b>Note:</b> this function is deprecated. You should now use <code>untrace-on-access</code> instead.

See also      **untrace-on-access**

### **untrace-new-instances-on-access**                          *Function*

Summary      Removes the tracing installed by **trace-new-instances-on-access**.

Package      **clos**

Signature      **untrace-new-instances-on-access** *class-designator* => t

Arguments      *class-designator*    The class whose trap you want to remove.

Values      Returns t.

Description      Removes the tracing installed by **trace-new-instances-on-access**.

See also      **trace-new-instances-on-access**  
**untrace-on-access**

### **untrace-on-access**                          *Function*

Summary      Removes the tracing installed by **trace-on-access**.

Package      **clos**

Signature      **untrace-on-access** *instance* => t

Arguments      *instance*                A class instance

Values      Returns t.

Description      Removes any trace installed on *instance* by **trace-on-access**.

See also      **trace-on-access**  
                 **untrace-new-instances-on-access**

## The COMM Package

This chapter provides reference entries for the functions in the `comm` package.

The `comm` package provides the TCP/IP interface. TCP/IP sockets can be used to communicate between processes and machines and the mechanism allows LispWorks to connect to or implement a server. It also allows using Secure Sockets Layer (SSL) processing in the socket.

The `comm` package also provides the Asynchronous I/O API including UDP sockets as described in “Asynchronous I/O” on page 411.

An overview of this functionality is in Chapter 25, “TCP and UDP socket communication and SSL”.

Before the interface can be used the module “`comm`” must be loaded using

```
(require "comm")
```

<code>accept-tcp-connections-creating-async-io-states</code>	<i>Function</i>
--	-----------------

Summary	Starts accepting TCP connections to a port within a <code>wait-state-collection</code> .
---------	--

Package	<code>comm</code>
---------	-------------------

Signature	<pre>accept-tcp-connections-creating-async-io-states collection service connection-function &amp;key init-function init-timeout backlog address nodelay keepalive ipv6 create-state name queue- output handle-name user-info ssl-ctx ssl-side ctx-configure-callback ssl-configure-callback handshake-timeout ssl-error-callback =&gt; accepting-handle</pre>
Arguments	<p><i>collection</i>      A <code>wait-state-collection</code>.</p> <p><i>service</i>        An integer, a string or <code>nil</code>.</p> <p><i>connection-function</i></p> <p>                    A function designator.</p> <p><i>init-function</i>    <code>nil</code> or a function designator.</p> <p><i>init-timeout</i>     <code>nil</code> or a non-negative real number.</p> <p><i>backlog</i>        <code>nil</code> or a positive integer.</p> <p><i>address</i>        An integer, an <code>ipv6-address</code> object, a string or <code>nil</code>.</p> <p><i>nodelay</i>        A generalized boolean.</p> <p><i>keepalive</i>      A generalized boolean.</p> <p><i>ipv6</i>            The keyword <code>:any</code>, <code>nil</code>, <code>t</code> or the keyword <code>:both</code>.</p> <p><i>create-state</i>    A boolean.</p> <p><i>queue-output</i>    A boolean.</p> <p><i>name</i>            A Lisp object.</p> <p><i>handle-name</i>    A Lisp object.</p> <p><i>user-info</i>       A Lisp object.</p> <p><i>ssl-side</i>       One of the keywords <code>:client</code>, <code>:server</code> or <code>:both</code>.</p> <p><i>ssl-ctx</i>        A symbol or a foreign pointer.</p>

*ctx-configure-callback*

A function designator or `nil`. The default value is `nil`.

*ssl-configure-callback*

A function designator or `nil`. The default value is `nil`.

*handshake-timeout*

A `real` or `nil` (the default).

*ssl-error-callback*

A function designator..

Values      *accepting-handle* An `accepting-handle` object.

Description    The function `accept-tcp-connections-creating-async-io-states` starts accepting TCP connections to the port service within the `wait-state-collection` collection.

*service* is interpreted as described in “Specifying the target for connecting and binding a socket” on page 408.

Each time a connection is made, *connection-function* is called with two arguments: *accepting-handle* and (by default) a new `async-io-state` for the connected socket. The function typically calls `async-io-state-read-buffer`, `async-io-state-write-buffer` or `async-io-state-read-with-checking` to start performing I/O. The keyword `:create-state` can be used to tell `accept-tcp-connections-creating-async-io-states` not to create the state and instead pass the socket itself. This is useful when you want to do the I/O “somewhere else”, either by creating a `socket-stream` and using ordinary read/write functions on it, or using a different `wait-state-collection`. The default value of *create-state* is `t`.

If *init-function* is non-nil, it is called after the listening socket has been bound to the service. *init-function* should take one argument: *socket*. *socket* is the socket used by the server, which can be used to determine the bound port number by calling `get-socket-address`.

If the port number specified by *service* is already in use, then `accept-tcp-connections-creating-async-io-states` periodically tries to bind to the port number for up to 1 minute (or *init-timeout* seconds if this is non-nil).

*queue-output* controls what happens if you try to perform a write operation on any of the states that `accept-tcp-connections-creating-async-io-states` creates while another write operation is in progress on the same state. When *queue-output* is `nil`, such an operation will cause an error. When *queue-output* is non-nil, the second write operation is queued and actually executed later. The default value of *queue-output* is `nil`.

The result *accepting-handle* is an object of type `accepting-handle`, which is the same object that will be passed to the *connection-function*. It can be used to stop accepting and closing the socket by `close-accepting-handle`, and also retrieving the socket.

*handle-name* and *user-info* are stored in the `accepting-handle` object. The *user-info* is not touched in any way by the system, and it is intended for you to pass information to the *connection-function*. *handle-name* is used when printing the handle, but is not accessed otherwise.

When *ssl-ctx* is non-nil, `accept-tcp-connections-creating-async-io-states` always creates an `async-io-state` (ignoring *create-state*), and attaches SSL to it. *ssl-side*, *ssl-ctx*, *ctx-configure-callback*, *ssl-configure-callback* and *handshake-timeout* are interpreted as described in “Keyword arguments for use with SSL” on page 421.

`ssl-error-callback` defaults to `error`. It is called when there is any error while attaching SSL to the new socket. Such errors can be either the result of an error in the configuration functions, or (more commonly) an error during the SSL handshake. `ssl-error-callback` is called from the thread of the `wait-state-collection` that was passed to `accept-tcp-connections-creating-async-io-states`. The socket is discarded before `Sssl-error-callback` is called.

For details of `backlog`, `address`, `nodelay`, `keepalive` and `ipv6`, see `start-up-server`.

The default value of `nodelay` is `t`.

The default value of `ipv6` is `:any`.

The default value of `name` is a string "Listening".

**Notes** `accept-tcp-connections-creating-async-io-states` binds the socket synchronously, that is when it returns successfully the socket is already bound. However, if it already started accepting connections. If you need to access the socket after binding and before starting to accept connections, use the `init-function` argument.

**See also** `create-async-io-state`  
`create-async-io-state-and-connected-tcp-socket`  
“The Async-I/O-State API” on page 412  
`accepting-handle`  
`accepting-handle-local-port`  
`close-accepting-handle`

	<i>Type</i>
<b>accepting-handle</b>	
<b>Summary</b>	The type of object returned by <code>accept-tcp-connections-creating-async-io-states</code> .
<b>Package</b>	<code>comm</code>

Signature	<code>accepting-handle</code>
Description	<p><code>accepting-handle</code> is the type of the object that is returned by <code>accept-tcp-connections-creating-async-io-states</code> and is passed as the first argument to the <i>connection-function</i> of <code>accept-tcp-connections-creating-async-io-states</code>.</p> <p>The handle contains the collection with which it is associated, the underlying socket, and the <i>user-info</i> and <i>handle-name</i> that were passed to <code>accept-tcp-connections-creating-async-io-states</code>.</p>
See also	<code>accept-tcp-connections-creating-async-io-states</code> <code>close-accepting-handle</code> <code>accepting-handle-socket</code> <code>accepting-handle-collection</code> <code>accepting-handle-local-port</code> <code>accepting-handle-user-info</code> <code>accepting-handle-name</code>

	<i>Function</i>
Summary	Returns the collection associated with an accepting handle.
Package	<code>comm</code>
Signature	<code>accepting-handle-collection accepting-handle =&gt; result</code>
Arguments	<code>accepting-handle</code> An <code>accepting-handle</code> .
Values	<code>result</code> A collection or <code>nil</code> .
Description	The function <code>accepting-handle-collection</code> returns the collection associated with <code>accepting-handle</code> .

*accepting-handle* has to be an accepting handle, currently that means the result of `accept-tcp-connections-creating-async-io-states`.

*result* is the collection that was supplied to `accept-tcp-connections-creating-async-io-states`, but for a closed handle *result* is `nil`.

See also      `accepting-handle`  
                 `accept-tcp-connections-creating-async-io-states`

## **accepting-handle-name** *Function*

Summary      Returns the name associated with an accepting handle.

Package      `comm`

Signature      `accepting-handle-name accepting-handle => name`

Arguments      *accepting-handle* An `accepting-handle`.

Values      *name*      A Lisp object.

Description      The function `accepting-handle-name` returns the name associated with the accepting handle *accepting-handle*, which is the *handle-name* argument to `accept-tcp-connections-creating-async-io-states`.

This name is used when printing the handle, so its printed representation should be reasonably short. Otherwise it is not restricted.

See also      `accepting-handle`  
                 `accept-tcp-connections-creating-async-io-states`

## **accepting-handle-local-port** *Function*

Summary	Returns the local port number to which the socket in an <b>accepting-handle</b> was bound.	
Package	<b>comm</b>	
Signature	<b>accepting-handle-local-port</b> <i>accepting-handle</i> => <i>port-number</i>	
Arguments	<i>accepting-handle</i> An object of type <b>accepting-handle</b> .	
Values	<i>port-number</i>	An integer.
Description	The function <b>accepting-handle-local-port</b> returns the local port number to which the socket in the <b>accepting-handle</b> <i>accepting-handle</i> was bound.	
See also	<a href="#"><b>accepting-handle</b></a> <a href="#"><b>accept-tcp-connections-creating-async-io-states</b></a>	

## **accepting-handle-socket** *Function*

Summary	Returns the socket associated with an accepting handle.	
Package	<b>comm</b>	
Signature	<b>accepting-handle-socket</b> <i>accepting-handle</i> => <i>result</i>	
Arguments	<i>accepting-handle</i> An <b>accepting-handle</b> .	
Values	<i>result</i>	A socket or <b>nil</b> .
Description	The function <b>accepting-handle-socket</b> returns the socket associated with <i>accepting-handle</i> .	

*accepting-handle* has to be an accepting handle, currently that means the result of `accept-tcp-connections-creating-async-io-states`.

*result* is the socket that was created by `accept-tcp-connections-creating-async-io-states`, but for a closed handle *result* is `nil`.

Notes	The socket "belongs" to the handle, and cannot be used for communication by other code. You can use accessors like <code>get-socket-address</code> on it.
See also	<code>accepting-handle</code> <code>accept-tcp-connections-creating-async-io-states</code>

## **accepting-handle-user-info** *Function*

Summary	Returns the <i>user-info</i> associated with an accepting handle.	
Package	<code>comm</code>	
Signature	<code>accepting-handle-user-info accepting-handle =&gt; result</code>	
Arguments	<i>accepting-handle</i> An <code>accepting-handle</code> .	
Values	<i>result</i>	A Lisp object.
Description	<p>The function <code>accepting-handle-user-info</code> returns the <i>user-info</i> associated with the handle <i>accepting-handle</i>, which is the <i>user-info</i> argument to <code>accept-tcp-connections-creating-async-io-states</code>.</p> <p>The system does nothing with the <i>user-info</i>, and its purpose is to allow you to pass information to the <i>connection-function</i> of <code>accept-tcp-connections-creating-async-io-states</code>.</p>	

See also      **accepting-handle**  
**accept-tcp-connections-creating-async-io-states**

## apply-in-wait-state-collection-process                          *Function*

Summary	Applies a function in the process that is associated with a <b>wait-state-collection</b> .							
Package	<b>comm</b>							
Signature	<b>apply-in-wait-state-collection-process</b> <i>collection</i> <i>function</i> <i>&amp;rest args</i>							
Arguments	<table> <tr> <td><i>collection</i></td><td>A <b>wait-state-collection</b>.</td></tr> <tr> <td><i>function</i></td><td>A function designator.</td></tr> <tr> <td><i>args</i></td><td>Lisp objects.</td></tr> </table>		<i>collection</i>	A <b>wait-state-collection</b> .	<i>function</i>	A function designator.	<i>args</i>	Lisp objects.
<i>collection</i>	A <b>wait-state-collection</b> .							
<i>function</i>	A function designator.							
<i>args</i>	Lisp objects.							
Description	<p>The function <b>apply-in-wait-state-collection-process</b> applies <i>function</i> to the arguments <i>args</i> in the process that is associated with <i>collection</i>.</p> <p>A process is associated with <i>collection</i> when it calls <b>wait-for-wait-state-collection</b>, typically from <b>loop-processing-wait-state-collection</b>. Normally only one process will do this for each individual <b>wait-state-collection</b>.</p> <p><b>apply-in-wait-state-collection-process</b> is asynchronous. It sends an appropriate message to the process or <i>collection</i>, and returns immediately, even if it is called from that process. The application happens at an undefined time inside the scope of call to <b>call-wait-state-collection</b> for <i>collection</i>.</p> <p>There is no documented return value.</p>

wait-state-collection
```

## async-io-state

## *System Class*

**Summary** A class of objects that can be used to perform asynchronous I/O.

## Package comm

Description Instances of the system class `async-io-state` can be used to perform asynchronous I/O.

See also [async-io-state-collection](#)  
[async-io-state-max-read](#)  
[async-io-state-name](#)  
[async-io-state-object](#)  
[async-io-state-old-length](#)  
[async-io-state-read-status](#)  
[async-io-state-read-timeout](#)  
[async-io-state-write-status](#)  
[async-io-state-write-timeout](#)  
[async-io-state-user-info](#)  
“The Async-I/O-State API” on page 10

## async-io-state-abort

## *Function*

**Summary** Stops I/O and callbacks on an `async-io-state` and calls an abort callback.

## Package comm

**Signature**      **async-io-state-abort** **async-io-state** **abort-callback** &  
optional  
**direction**

Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
	<code>abort-callback</code>	A function designator.
	<code>direction</code>	One of the keywords <code>:input</code> , <code>:output</code> and <code>:io</code> .
Values	None.	
Description	<p>The function <code>async-io-state-abort</code> stops further I/O and calls to any callbacks for direction <code>direction</code> in <code>async-io-state</code> and asynchronously calls <code>abort-callback</code> with the same arguments that the callback for a running operation would be called, except when <code>direction</code> is <code>:io</code>, when the callback is called with the state only.</p> <p>The default value of <code>direction</code> is <code>:input</code>.</p> <p>If by the time <code>abort-callback</code> is called there is no active operation, then <code>abort-callback</code> is called with <code>async-io-state</code> and <code>nil</code> for the other arguments.</p> <p>If <code>async-io-state-abort</code> is called while a callback is running, its effect is delayed until the callback returns.</p> <p><code>abort-callback</code> can do what the other callbacks can do. In particular, it can reuse <code>async-io-state</code>, and when it aborts <code>async-io-state-read-with-checking</code> it can decide how much of the buffered data to discard by calling <code>async-io-state-discard</code>.</p>	
Notes	<p>Due to the asynchronous delay between the time that <code>async-io-state-abort</code> is called and the time that <code>abort-callback</code> is called, the callback of the operation may have already been called, so if the <code>abort-callback</code> does anything except closing <code>async-io-state</code> it will normally have to check the state's <code>async-io-state-read-status</code>.</p>	
See also	<p><code>async-io-state-abort-and-close</code>  “The Async-I/O-State API” on page 412</p>	

	<i>Function</i>
Summary	Aborts any I/O on an <code>async-io-state</code> , closes it and optionally calls a callback.
Package	<code>comm</code>
Signature	<code>async-io-state-abort-and-close async-io-state &amp;key close-callback keep-alive-p</code>
Arguments	<p><code>async-io-state</code> An <code>async-io-state</code>.</p> <p><code>keep-alive-p</code> A generalized boolean.</p> <p><code>close-callback</code> A function designator for a function of one argument, or <code>nil</code>.</p>
Values	None.
Description	<p>The function <code>async-io-state-abort-and-close</code> aborts any I/O on <code>async-io-state</code>, closes it and optionally calls the <code>close-callback</code>.</p> <p><code>async-io-state-abort-and-close</code> first aborts any I/O operation that is in progress, and then closes the state (using <code>close-async-io-state</code>).</p> <p>The value of <code>keep-alive-p</code> is passed to <code>close-async-io-state</code>.</p> <p>If <code>close-callback</code> is non-nil, it should be a function taking one argument. It is called with the state as its argument after the state is closed.</p> <p><code>async-io-state-abort-and-close</code> is asynchronous. The state is known to be closed only when the <code>close-callback</code> is called.</p> <p>See <code>close-async-io-state</code> about accessing the state after it is closed.</p>

See also      **async-io-state-abort**  
**close-async-io-state**  
“[The Async-I/O-State API](#)” on page 412

## async-io-state-address                          *Function*

Summary      Returns the local address and port number for an **async-io-state** that has a socket.

Package      **comm**

Signature     **async-io-state-address** **async-io-state** => **address**, **port**

Arguments    **async-io-state**    An **async-io-state**.

Values        **address**        An integer or an **ipv6-address** object.  
**port**        An integer.

Description    The function **async-io-state-address** returns the local address and port number for **async-io-state** if it has a socket (currently all states).  
**address** is the local host address of the socket in the state.  
**port** is the local port number of the socket in the state.

See also     **async-io-state-peer-address**  
**get-socket-address**  
“[The Async-I/O-State API](#)” on page 412

## async-io-state-attach-ssl                          *Function*

Summary      Attaches SSL to an **async-io-state** that contains a TCP socket.

Package      **comm**

Signature	<code>async-io-state-attach-ssl</code> <code>async-io-state callback &amp;key ssl-side</code> <code>ssl-ctx</code> <code>ctx-configure-callback</code> <code>ssl-configure-callback</code>
Arguments	<p><code>async-io-state</code> An <code>async-io-state</code>.</p> <p><code>callback</code> A function designator for a function with two arguments.</p> <p><code>ssl-side</code> One of the keywords <code>:client</code>, <code>:server</code> or <code>:both</code>.</p> <p><code>ssl-ctx</code> A symbol or a foreign pointer.</p> <p><code>ctx-configure-callback</code></p> <p>A function designator or <code>nil</code>. The default value is <code>nil</code>.</p> <p><code>ssl-configure-callback</code></p> <p>A function designator or <code>nil</code>. The default value is <code>nil</code>.</p> <p><code>handshake-timeout</code></p> <p>A <code>real</code> or <code>nil</code> (the default).</p>
Values	None
Description	<p>The function <code>async-io-state-attach-ssl</code> attaches SSL to <code>async-io-state</code>, which must contain a TCP socket, typically the result of <code>create-async-io-state</code> or a state created by <code>accept-tcp-connections-creating-async-io-states</code>. <code>async-io-state</code> must not have SSL attached to it already.</p> <p><code>ssl-side</code>, <code>ssl-ctx</code>, <code>ctx-configure-callback</code>, <code>ssl-configure-callback</code> and <code>handshake-timeout</code> are interpreted as described in “Keyword arguments for use with SSL” on page 421. <code>ssl-ctx</code> defaults to <code>t</code> and <code>ssl-side</code> defaults to <code>:server</code>.</p> <p>When SSL has been attached successfully or otherwise, <code>callback</code> is called with two arguments: <code>async-io-state</code> and an error-indicator. The error-indicator is <code>nil</code> when successful, other-</p>

wise it is a list of a format control-string and args, suitable for applying to `format`. When the error-indicator is non-nil, `async-io-state` is not attached to SSL.

`async-io-state-attach-ssl` must not be called when there is any other operation on `async-io-state` and new operations on `async-io-state` must not be started until `callback` has been called.

Notes	<code>create-async-io-state-and-connected-tcp-socket</code> and <code>accept-tcp-connections-creating-async-io-states</code> can attach SSL themselves, and in most cases that is the best way to do it. <code>async-io-state-attach-ssl</code> allows the attachment to be done later.
See also	<code>create-async-io-state-and-connected-tcp-socket</code> <code>accept-tcp-connections-creating-async-io-states</code> <code>async-io-state-detach-ssl</code> “Using Asynchronous I/O with SSL” on page 421

	<i>Function</i>
Summary	Returns the length of the buffered data in an <code>async-io-state</code> .
Package	<code>comm</code>
Signature	<code>async-io-state-buffered-data-length</code> <code>async-io-state</code> => <code>length</code>
Arguments	<code>async-io-state</code> An <code>async-io-state</code> .
Values	<code>length</code> A non-negative integer.
Description	The function <code>async-io-state-buffered-data-length</code> returns the length of the buffered data in <code>async-io-state</code> .

See also      **async-io-state-get-buffered-data**  
                “The Async-I/O-State API” on page 412

## async-io-state-ctx

*Function*

Summary      Accesses the **SSL\_CTX** attached to an **async-io-state**.

Package      **comm**

Signature     **async-io-state-ctx** **async-io-state** => **ssl-ctx-pointer**

Arguments    **async-io-state**    An **async-io-state**.

Values        **ssl-ctx-pointer**   A foreign pointer of type **ssl-ctx-pointer**,  
                 or **nil**.

Description     The function **async-io-state-ctx** accesses the **SSL\_CTX**  
                that is attached to the **async-io-state** **async-io-state**.  
  
                It returns **nil** if SSL is not attached.

See also      **async-io-state**  
                  **ssl-ctx-pointer**

## async-io-state-detach-ssl

*Function*

Summary      Detaches SSL to an **async-io-state** that contains a TCP  
                socket.

Package      **comm**

Signature    **async-io-state-detach-ssl** **async-io-state** **callback**

Arguments    **async-io-state**    An **async-io-state**.

	<i>callback</i>	A function designator for a function with one argument.
Values	None	
Description		The function <code>async-io-state-detach-ssl</code> detaches SSL from <code>async-io-state</code> . Subsequent communications through <code>async-io-state</code> will be without SSL.  When SSL has been detached, <i>callback</i> is called with <code>async-io-state</code> .  If <code>async-io-state</code> did not have SSL attached then <code>async-io-state-detach-ssl</code> has no effect.  <code>async-io-state-detach-ssl</code> must not be called when there is any other operation on <code>async-io-state</code> , and new operations on <code>async-io-state</code> must not be started until <i>callback</i> has been called.
Notes		There is no need to call <code>async-io-state-detach-ssl</code> before <code>close-async-io-state</code> because that also detaches SSL.
See also		<code>async-io-state-attach-ssl</code> <code>close-async-io-state</code> “Using Asynchronous I/O with SSL” on page 421

	<b>Function</b>
Summary	Returns the <code>wait-state-collection</code> of an <code>async-io-state</code> .
Package	<code>comm</code>
Signature	<code>async-io-state-collection async-io-state -&gt; collection</code>
Arguments	<code>async-io-state</code> An <code>async-io-state</code> .

Values	<i>collection</i>	A <b>wait-state-collection</b> .
Description	The function <b>async-io-state-collection</b> returns the <b>wait-state-collection</b> associated with <b>async-io-state</b> .	
See also	<b>async-io-state</b> <b>wait-state-collection</b> “The Async-I/O-State API” on page 412	

## **async-io-state-discard** *Function*

Summary	Discards some bytes from the internal buffer in an <b>async-io-state</b> .	
Package	<b>comm</b>	
Signature	<b>async-io-state-discard</b> <b>async-io-state</b> <b>discard</b> => <b>unread-buffer-length</b>	
Arguments	<b>async-io-state</b>	An <b>async-io-state</b> .
	<b>discard</b>	A positive integer.
Values	<b>unread-buffer-length</b> A non-negative integer.	
Description	<p>The function <b>async-io-state-discard</b> discards the first <i>discard</i> bytes from the internal buffer in <b>async-io-state</b>. The rest of the buffer is preserved for future reading.</p> <p><b>async-io-state-discard</b> must only be called inside the scope of the <i>callback</i> of <b>async-io-state-read-with-checking</b>. Once <b>async-io-state-discard</b> has been called, the <i>callback</i> must not access the buffer again.</p> <p>The return value <b>unread-buffer-length</b> is the remaining number of bytes in the buffer.</p>

                 “The Async-I/O-State API” on page 412

	<i>Function</i>				
Summary	Stops the current read operation in an <b>async-io-state</b> .				
Package	<b>comm</b>				
Signature	<b>async-io-state-finish</b> <i>async-io-state</i> &optional <i>discard</i> => <i>unread-buffer-length</i>				
Arguments	<table border="0"> <tr> <td><i>async-io-state</i></td><td>An <b>async-io-state</b>.</td></tr> <tr> <td><i>discard</i></td><td>A positive integer or <b>nil</b>.</td></tr> </table>	<i>async-io-state</i>	An <b>async-io-state</b> .	<i>discard</i>	A positive integer or <b>nil</b> .
<i>async-io-state</i>	An <b>async-io-state</b> .				
<i>discard</i>	A positive integer or <b>nil</b> .				
Values	<table border="0"> <tr> <td><i>unread-buffer-length</i></td><td></td></tr> <tr> <td></td><td>A non-negative integer.</td></tr> </table>	<i>unread-buffer-length</i>			A non-negative integer.
<i>unread-buffer-length</i>					
	A non-negative integer.				
Description	<p>The function <b>async-io-state-finish</b> stops the current read operation in <i>async-io-state</i>, so no further calls to the <b>async-io-state-read-with-checking</b> <i>callback</i> will occur. If <i>discard</i> is non-nil, then it discards the first <i>discard</i> bytes from the internal buffer in <i>async-io-state</i>. The rest of the buffer is preserved for future reading.</p> <p><b>async-io-state-finish</b> must only be called inside the scope of the <i>callback</i> of <b>async-io-state-read-with-checking</b>. Once <b>async-io-state-finish</b> has been called, the <i>callback</i> must not access the buffer again and a new read operation can be started.</p> <p>The return value <i>unread-buffer-length</i> is the remaining number of bytes in the buffer.</p>				
See also	<b>async-io-state-read-with-checking</b> “The Async-I/O-State API” on page 412				

	<i>Function</i>
Summary	Copies buffered data from an <b>async-io-state</b> and discards it from the state.
Package	<code>comm</code>
Signature	<code>async-io-state-get-buffered-data async-io-state buffer &amp;key start end =&gt; length</code>
Arguments	<p><b>async-io-state</b> An <b>async-io-state</b>.</p> <p><b>buffer</b> A <b>cl:base-string</b> or an 8-bit <b>cl:simple-array</b>.</p> <p><b>start</b> A lower bounding index designator for <b>buffer</b>.</p> <p><b>end</b> An upper bounding index designator for <b>buffer</b>.</p>
Values	<b>length</b> A non-negative integer.
Description	<p>The function <b>async-io-state-get-buffered-data</b> copies to the buffer <b>buffer</b> (between <b>start</b> and <b>end</b>) as much as possible of the buffered data in <b>async-io-state</b> and discards it from <b>async-io-state</b>.</p> <p>The default value of <b>start</b> is 0. The default value of <b>end</b> is the length of <b>buffer</b>.</p> <p>The return value <b>length</b> is the number of elements copied into <b>buffer</b>.</p> <p><b>async-io-state-get-buffered-data</b> cannot be called while an operation is active in <b>async-io-state</b>, that is between the call to <b>async-io-state-read-buffer</b> or <b>async-io-state-write-buffer</b>, and the call to the callback or <b>async-io-state-abort</b>, or between a call to <b>async-io-state-read-with-checking</b> and the call to <b>async-io-state-finish</b> or <b>async-io-state-abort</b>.</p>

Notes	Use <code>async-io-state-buffered-data-length</code> to find how much buffered data there is in <code>async-io-state</code> .
See also	<code>async-io-state-buffered-data-length</code> “The Async-I/O-State API” on page 412

## **async-io-state-handshake** *Function*

Summary	Perform a SSL handshake on an <code>async-io-state</code> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-handshake</code> <code>async-io-state</code> <code>callback</code> & <code>optional timeout</code>	
Arguments	<code>async-io-state</code>	A <code>socket-stream</code> .
	<code>callback</code>	A function designator for a function with two arguments.
	<code>timeout</code>	<code>nil</code> or a real.
Values	None.	
Description	<p>The function <code>async-io-state-handshake</code> performs a handshake on <code>async-io-state</code>, which must be attached to SSL.</p> <p>When the handshake has finished successfully or failed, <code>callback</code> is called with two arguments: <code>async-io-state</code> and an error-indicator. The error-indicator is <code>nil</code> when successful, otherwise it is a list suitable for an error call as in <code>(apply 'error error-indicator)</code>. The <code>async-io-state-read-status</code> of <code>async-io-state</code> is also set appropriately.</p> <p>If the handshake does not finish in <code>timeout</code> seconds, <code>callback</code> is called with non-nil error-indicator: <code>("Handshake timed out")</code>, and the <code>async-io-state-read-status</code> is set to <code>:timeout</code>. If the other side closes the socket cleanly, <code>callback</code> is called error-indicator: <code>("SSL connection closed")</code>,</p>	

and the `async-io-state-read-status` is set to `:eof`. Other cases indicate an actual error in the handshake.

`async-io-state-handshake` must not be called when there is any other operation on `async-io-state` and new operations on `async-io-state` must not be started until `callback` has been called.

Notes	If SSL was attached with <code>ssl-side :both</code> , then you will need to specify which side to take in the handshake by calling <code>ssl-set-accept-state</code> or <code>ssl-set-connect-state</code> with the <code>ssl-pointer</code> return by <code>socket-stream-ssl</code> .
See also	<code>async-io-state</code> “Using SSL” on page 418

## **async-io-state-max-read** *Accessor*

Summary	Accesses the maximum bytes to read of an <code>async-io-state</code> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-max-read</code> <code>async-io-state =&gt; max-read</code>  <code>setf</code> ( <code>async-io-state-max-read</code> <code>async-io-state</code> ) <code>max-read =&gt; max-read</code>	
Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
	<code>max-read</code>	An integer.
Values	<code>max-read</code>	An integer.
Description	The accessor <code>async-io-state-max-read</code> is used to read and write the maximum bytes to try to read of <code>async-io-state</code> . <code>max-read</code> is an integer specifying the maximum number of bytes to try to read between calls to the callback in <code>async-io-state-read-with-checking</code> .	

See also      **async-io-state**  
**async-io-state-read-with-checking**  
“[The Async-I/O-State API](#)” on page 412

## **async-io-state-name** *Accessor*

Summary      Accesses the name of an **async-io-state**.

Package      **comm**

Signature      **async-io-state-name** **async-io-state** => **name**  
**setf** (**async-io-state-name** **async-io-state**) **name** => **name**

Arguments      **async-io-state**    An **async-io-state**.  
**name**            A Lisp object.

Values      **name**            A Lisp object.

Description      The accessor **async-io-state-name** is used to access the *name* of **async-io-state**. This names the state for debugging purposes.

See also      **async-io-state**  
**create-async-io-state**  
“[The Async-I/O-State API](#)” on page 412

## **async-io-state-object** *Function*

Summary      Returns the object used to create an **async-io-state**.

Package      **comm**

Signature      **async-io-state-object** **async-io-state** => **object**

Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
Values	<code>object</code>	A <code>socket-stream</code> or an integer.
Description		The function <code>async-io-state-object</code> returns the <i>object</i> that was supplied in the call to <code>create-async-io-state</code> that created <code>async-io-state</code> .
See also		<code>async-io-state</code> <code>create-async-io-state</code> “The Async-I/O-State API” on page 412

## **async-io-state-old-length** *Function*

Summary	Returns the old length of an <code>async-io-state</code> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-old-length</code> <code>async-io-state</code> => <code>old-length</code>	
Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
Values	<code>old-length</code>	An integer.
Description		The function <code>async-io-state-old-length</code> is used to get the old length of <code>async-io-state</code> . <i>old-length</i> is an integer specifying the length of the old part in the buffer, that is the part that was seen in the previous invocation of the callback in <code>async-io-state-read-with-checking</code> .
See also		<code>async-io-state</code> <code>async-io-state-read-with-checking</code> “The Async-I/O-State API” on page 412

		<i>Function</i>
<b>async-io-state-peer-address</b>		
Summary	Returns the local address and port number for an <b>async-io-state</b> state that has a connected socket.	
Package	<code>comm</code>	
Signature	<code>async-io-state-peer-address</code>	<code>async-io-state =&gt; address, port</code>
Arguments	<code>async-io-state</code>	An <b>async-io-state</b> .
Values	<code>address</code>	An integer, an <b>ipv6-address</b> or <b>nil</b> .
	<code>port</code>	An integer or <b>nil</b> .
Description	The function <b>async-io-state-peer-address</b> returns the remote address and port number for <i>async-io-state</i> if it has a socket which is connected.  <i>address</i> is the remote host address of the socket in the state. <i>port</i> is the remote port number of the socket in the state. For an unconnected socket both <i>address</i> and <i>port</i> are <b>nil</b> .	
See also	 <a href="#"><b>async-io-state-address</b></a> <a href="#"><b>get-socket-peer-address</b></a> <a href="#">“The Async-I/O-State API” on page 412</a>	

		<i>Function</i>
<b>async-io-state-read-buffer</b>		
Summary	Asynchronously fills a buffer with bytes read from an <b>async-io-state</b> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-read-buffer</code>	<code>async-io-state buffer callback &amp;key start end timeout error-callback user-info</code>

Arguments	<i>async-io-state</i>	An <b>async-io-state</b> .
	<i>buffer</i>	A <b>cl:base-string</b> or an 8-bit <b>cl:simple-array</b> .
	<i>callback</i>	A function designator for a function of 3 arguments.
	<i>start</i>	A lower bounding index designator for <i>buffer</i> .
	<i>end</i>	An upper bounding index designator for <i>buffer</i> .
	<i>timeout</i>	<b>nil</b> or a positive real.
	<i>error-callback</i>	A function designator for a function of 3 arguments, or <b>nil</b> .
	<i>user-info</i>	A Lisp object.
Values	None.	
Description	<p>The function <b>async-io-state-read-buffer</b> asynchronously fills the buffer <i>buffer</i> between <i>start</i> and <i>end</i> with bytes read from <i>async-io-state</i>. When buffer is full (between <i>start</i> and <i>end</i>) or the <b>async-io-state-read-timeout</b> of <i>async-io-state</i> has passed, the <i>callback</i> is called like this:</p> <pre><b>callback</b> <i>async-io-state</i> <i>buffer</i> <i>number-of-bytes-read</i></pre> <p>If an error occurs during the I/O operation and <i>error-callback</i> is non-nil, then <i>error-callback</i> is called with these same arguments:</p> <pre><b>error-callback</b> <i>async-io-state</i> <i>buffer</i> <i>number-of-bytes-read</i></pre> <p>If <i>error-callback</i> is <b>nil</b>, then <i>callback</i> is called, so it should check for errors using <b>async-io-state-read-status</b>.</p> <p>The default value of <i>start</i> is 0. The default value of <i>end</i> is the length of <i>buffer</i>.</p>	

If the operation does not finish within the state's `async-io-state-read-timeout` period then state's `async-io-state-read-status` is set to `:timeout` and `callback` is called.

If `timeout` or `user-info` are supplied then they set `async-io-state-read-timeout` and `async-io-state-user-info` in `async-io-state` for this and subsequent operations.

If another read operation on the state is in progress, an error is signaled.

“The Async-I/O-State API” on page 412

## `async-io-state-read-status`

## `async-io-state-write-status`

## *Functions*

Summary	Returns the read or write status of an <code>async-io-state</code> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-read-status</code> <code>async-io-state</code> => <code>read-status</code> <code>async-io-state-write-status</code> <code>async-io-state</code> => <code>write-status</code>	
Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
Values	<code>read-status</code>	<code>nil</code> , <code>:eof</code> , <code>:timeout</code> or an error value.
	<code>write-status</code>	<code>nil</code> , <code>:eof</code> , <code>:timeout</code> or an error value.
Description	The function <code>async-io-state-read-status</code> returns the read status of <code>async-io-state</code> . <code>read-status</code> is <code>nil</code> for a working socket, <code>:eof</code> for end of file, <code>:timeout</code> if a timeout has occurred or some other values meaning an error has occurred.	

The function `async-io-state-write-status` returns the write status of `async-io-state`. `write-status` is `nil` for a working socket, `:eof` for end of file, `:timeout` if a timeout has occurred or some other values meaning an error has occurred.

`async-io-state`  
“The Async-I/O-State API” on page 412

## `async-io-state-read-timeout`

## `async-io-state-write-timeout`

## *Accessors*

Summary      Accesses the read and write timeouts of an `async-io-state`.

Package      `comm`

Signature      `async-io-state-read-timeout async-io-state => read-timeout`  
`setf (async-io-state-read-timeout async-io-state) read-timeout => read-timeout`  
  
`async-io-state-write-timeout async-io-state => write-timeout`  
`setf (async-io-state-write-timeout async-io-state) write-timeout => write-timeout`

Arguments      `async-io-state`      An `async-io-state`.

`read-timeout`      `nil` or a positive real.

`write-timeout`      `nil` or a positive real.

Values          `read-timeout`      `nil` or a positive real.

`write-timeout`      `nil` or a positive real.

Description      The accessor `async-io-state-read-timeout` is used to read and write the read timeout of `async-io-state`. `read-timeout` is `nil` if there is no timeout and otherwise is a timeout in seconds.

The accessor `async-io-state-write-timeout` is used to read and write the write timeout of `async-io-state`. `write-timeout` is `nil` if there is no timeout and otherwise is a timeout in seconds.

“The Async-I/O-State API” on page 412

	<i>Function</i>														
<b>async-io-state-read-with-checking</b>															
Summary	Repeatedly tries to read bytes from an <code>async-io-state</code> , and invokes a callback.														
Package	<code>comm</code>														
Signature	<code>async-io-state-read-with-checking async-io-state callback &amp;key timeout max-read error-callback user-info element-type</code>														
Arguments	<table> <tr> <td><code>async-io-state</code></td><td>An <code>async-io-state</code>.</td></tr> <tr> <td><code>callback</code></td><td>A function designator for a function of 3 arguments, or <code>nil</code>.</td></tr> <tr> <td><code>timeout</code></td><td><code>nil</code> or a positive real.</td></tr> <tr> <td><code>max-read</code></td><td>A positive integer.</td></tr> <tr> <td><code>error-callback</code></td><td>A function designator for a function of 3 arguments, or <code>nil</code>.</td></tr> <tr> <td><code>user-info</code></td><td>A Lisp object.</td></tr> <tr> <td><code>element-type</code></td><td>A type specifier.</td></tr> </table>	<code>async-io-state</code>	An <code>async-io-state</code> .	<code>callback</code>	A function designator for a function of 3 arguments, or <code>nil</code> .	<code>timeout</code>	<code>nil</code> or a positive real.	<code>max-read</code>	A positive integer.	<code>error-callback</code>	A function designator for a function of 3 arguments, or <code>nil</code> .	<code>user-info</code>	A Lisp object.	<code>element-type</code>	A type specifier.
<code>async-io-state</code>	An <code>async-io-state</code> .														
<code>callback</code>	A function designator for a function of 3 arguments, or <code>nil</code> .														
<code>timeout</code>	<code>nil</code> or a positive real.														
<code>max-read</code>	A positive integer.														
<code>error-callback</code>	A function designator for a function of 3 arguments, or <code>nil</code> .														
<code>user-info</code>	A Lisp object.														
<code>element-type</code>	A type specifier.														
Values	None.														
Description	The function <code>async-io-state-read-with-checking</code> repeatedly tries to read up to <code>async-io-state-max-read</code>														

more bytes from `async-io-state`, append them to the internal buffer and call `callback` like this:

```
callback async-io-state buffer end
```

`async-io-state` is the argument to `async-io-state-read-with-checking`, `buffer` is a `cl:simple-array` of element type `element-type` containing data from index 0 up to `end`, and `end` is a positive integer indicating the end of the filled part of `buffer`.

The buffer must not be modified or accessed outside the scope of the callback or after `async-io-state-discard` or `async-io-state-finish` have been called.

The element type of `buffer` is `element-type`, which can be `base-char`, `(unsigned-byte 8)` or `(signed-byte 8)`. The default value of `element-type` is `base-char`.

The callback is responsible for processing the data in the buffer and optionally indicating that the read operation is complete as follows:

- The function `async-io-state-old-length` can be used to find the length of the old part in the buffer, that is the part that contained data in the previous call to the callback. When `async-io-state-read-with-checking` is called, it resets the old length to 0, so `async-io-state-old-length` returns 0 in the first invocation of `callback`.
- You can use `async-io-state-discard` with `discard` between 0 and `end` to discard the first `discard` bytes of the buffer. This is typically done when the callback has processed some of the bytes and does not want to see them again. Until bytes are discarded explicitly, they are accumulated in the buffer for subsequent calls to the callback.
- When the callback decides that the operation is complete, it needs to call `async-io-state-finish`. This optionally discards bytes as described above, and keeps the remaining bytes for future read operations from `async-io-state`.

If the operation does not finish within the state's `async-io-state-read-timeout` period then the callback is called with the state's `async-io-state-read-status` set to `:timeout`.

If an error occurs during the I/O operation and `error-callback` is non-nil, then `error-callback` is called like this:

```
error-callback async-io-state buffer end
```

If `error-callback` is nil, then `callback` is called, so it should check for errors using `async-io-state-read-status`.

If `timeout`, `max-read` or `user-info` are supplied then they set `async-io-state-read-timeout`, `async-io-state-max-read` and `async-io-state-user-info` in `async-io-state` for this and subsequent operations.

If another read operation is in progress on the state, an error is signaled.

**Notes** Once the callback has called `async-io-state-finish` it can start further reading operations on `async-io-state`. The accessors `async-io-state-read-timeout`, `async-io-state-max-read` and `async-io-state-user-info` can be used to read and write the corresponding values in the callback.

**Examples** Reading http headers, which are separated from the http body by two consecutive newlines. We assume these functions:

1. `my-parse-http-headers` which takes a buffer, start and end and returns a parsed headers-object.
2. `my-read-http-body` takes an `async-io-state`, headers-object and a user-defined object and reads the body via the Async-IO-State API.
3. `my-record-socket-error` which takes a user defined object and the error flag and handles a socket error.
4. `find-nn-in-buffer` which takes buffer, start and end and returns the index of the first two consecutive newlines if any.

The callback is defined like this:

```
(defun http-header-reading-callback (state buffer end)
  (if-let (cannot-read
            (async-io-state-read-status state))
    (my-record-socket-error
      (async-io-state-user-info state)
      cannot-read)
    (let ((start (async-io-state-old-length state)))
      (let ((start-search-for-nn
              (if (zerop start) 0 (1- start))))
        (when-let (h-end (find-nn-in-buffer
                           buffer
                           start-search-for-nn
                           end))
          (let ((h-object (my-parse-http-headers
                           buffer 0 h-end)))
            (async-io-state-finish state (+ h-end 2))
            (my-read-http-body
              state
              h-object
              (async-io-state-user-info state))))))))
```

The callback is used like this:

```
(async-io-state-read-with-checking
  state
  'http-header-reading-callback)
```

                [async-io-state-write-buffer](#)  
                “The Async-I/O-State API” on page 412

## async-io-state-receive-message *Function*

Summary      Asynchronously receives a message from a socket.

Package      `comm`

Signature      `async-io-state-receive-message async-io-state buffer callback &key start end timeout error-callback needs-address user-info`

Arguments	<i>async-io-state</i>	An <code>async-io-state</code> .
	<i>buffer</i>	A <code>cl:base-string</code> or an 8-bit <code>cl:simple-array</code> .
	<i>callback</i>	A function designator.
	<i>start</i>	A lower bounding index designator for <i>buffer</i> .
	<i>end</i>	An upper bounding index designator for <i>buffer</i> .
	<i>timeout</i>	<code>nil</code> or a non-negative real.
	<i>error-callback</i>	A function designator.
	<i>needs-address</i>	A boolean.
	<i>user-info</i>	A Lisp object.
Values	None.	
Description	<p>The function <code>async-io-state-receive-message</code> starts a read operation of "receiving" on <i>async-io-state</i>, which means that when there is input on the socket it calls <code>recv</code> or <code>recvfrom</code> to read the data into <i>buffer</i> between <i>start</i> and <i>end</i>. The default value of <i>start</i> is 0. The default value of <i>end</i> is the length of <i>buffer</i>.</p> <p><i>callback</i> should be a function of 3 or 5 arguments. If the reading succeeds and <i>needs-address</i> is <code>nil</code>, then <i>callback</i> is called with this signature:</p> <pre><code>callback async-io-state buffer number-of-bytes-read</code></pre> <p>If the reading succeeds and <i>needs-address</i> is non-<code>nil</code>, then <i>callback</i> is called with this signature:</p> <pre><code>callback async-io-state buffer number-of-bytes-read ip-address port-number</code></pre> <p>where <i>ip-address</i> and <i>port-number</i> are the socket address of the sender, and can be used as the <i>hostspec</i> and <i>service</i> when</p>	

required. Typically these are used in `async-io-state-send-message-to-address` to send a message back to the sender.

The default value of `needs-address` is `nil`.

`error-callback`, `timeout`, `start`, `end` and `user-info` have the same meaning as in `async-io-state-read-buffer`.

- Notes
1. `async-io-state-receive-message` is typically used only with an `async-io-state` containing a UDP socket, created by `create-async-io-state-and-udp-socket`, `create-async-io-state-and-connected-udp-socket` or calling `create-async-io-state` with `udp` non-`nil`.
  2. The socket may or may not be connected.

Example      (`example-edit-file "async-io/udp"`)

See also      `create-async-io-state-and-udp-socket`  
`create-async-io-state-and-connected-udp-socket`  
`async-io-state-send-message`  
`async-io-state-send-message-to-address`  
“The Async-I/O-State API” on page 412

async-io-state-send-message		<i>Function</i>
Summary	Asynchronously sends a message on a connected socket.	
Package	<code>comm</code>	
Signature	<code>async-io-state-send-message</code> <code>async-io-state</code> <code>buffer</code> <code>callback</code> <code>&amp;key</code> <code>start</code> <code>end</code> <code>timeout</code> <code>error-callback</code> <code>user-info</code>	
Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
	<code>buffer</code>	A <code>cl:base-string</code> or an 8-bit <code>cl:simple-array</code> .

<i>callback</i>	A function designator for a function of 1 argument.
<i>start</i>	A lower bounding index designator for <i>buffer</i> .
<i>end</i>	An upper bounding index designator for <i>buffer</i> .
<i>timeout</i>	<code>nil</code> or a non-negative real.
<i>error-callback</i>	A function designator.
<i>user-info</i>	A Lisp object.
Values	None.
Description	<p>The function <code>async-io-state-send-message</code> asynchronously sends a message from <i>buffer</i> between <i>start</i> and <i>end</i>. The socket in <code>async-io-state</code> must be connected. When the send is successful, <i>callback</i> is called with <code>async-io-state</code> as its only argument.</p> <p>The default value of <i>start</i> is 0. The default value of <i>end</i> is the length of <i>buffer</i>.</p> <p><i>error-callback</i>, <i>timeout</i>, <i>start</i>, <i>end</i> and <i>user-info</i> have the same meaning as in <code>async-io-state-write-buffer</code>.</p>
Notes	<p><code>async-io-state-send-message</code> is typically used only with an <code>async-io-state</code> containing a UDP socket, created by <code>create-async-io-state-and-udp-socket</code>, <code>create-async-io-state-and-connected-udp-socket</code> or calling <code>create-async-io-state</code> with <i>udp</i> non-nil.</p> <p>The contents of <i>buffer</i> must not be changed until <i>callback</i> has been called.</p> <p>For unconnected UDP sockets, use <code>async-io-state-send-message-to-address</code>.</p>

See also `create-async-io-state-and-connected-udp-socket`  
`async-io-state-receive-message`  
`async-io-state-send-message-to-address`  
“The Async-I/O-State API” on page 412

## **async-io-state-send-message-to-address** *Function*

Summary	Asynchronously sends a message on an unconnected socket.
Package	<code>comm</code>
Signature	<code>async-io-state-send-message-to-address (async-io-state hostspec service buffer callback &amp;key start end timeout error-callback user-info)</code>
Arguments	<p><code>async-io-state</code> An <code>async-io-state</code>.</p> <p><code>hostspec, service</code> Specify the socket address to send to in the standard way.</p> <p><code>buffer</code> A <code>cl:base-string</code> or an 8-bit <code>cl:simple-array</code>.</p> <p><code>callback</code> A function designator for a function of 1 argument.</p> <p><code>start</code> A lower bounding index designator for <code>buffer</code>.</p> <p><code>end</code> An upper bounding index designator for <code>buffer</code>.</p> <p><code>timeout</code> <code>nil</code> or a non-negative real.</p> <p><code>error-callback</code> A function designator.</p> <p><code>user-info</code> A Lisp object.</p>
Values	None.

Description	<p>The function <code>async-io-state-send-message-to-address</code> asynchronously sends a message from <i>buffer</i> between <i>start</i> and <i>end</i> to the socket address which is specified by <i>hostspec</i> and <i>service</i>. For the interpretation of <i>hostspec</i> and <i>service</i> see “Specifying the target for connecting and binding a socket” on page 408.</p> <p>The default value of <i>start</i> is 0. The default value of <i>end</i> is the length of <i>buffer</i>.</p> <p>The socket in <code>async-io-state</code> must not be connected. When the sending is successful, <i>callback</i> is called with <code>async-io-state</code> as its only argument.</p> <p><i>error-callback</i>, <i>timeout</i>, <i>start</i>, <i>end</i> and <i>user-info</i> have the same meaning as in <code>async-io-state-write-buffer</code>.</p>
Notes	<ol style="list-style-type: none"> <li>1. <code>async-io-state-send-message-to-address</code> is typically used only with an <code>async-io-state</code> containing a UDP socket, created by <code>create-async-io-state-and-udp-socket</code>, <code>create-async-io-state-and-connected-udp-socket</code> or calling <code>create-async-io-state</code> with <i>udp</i> non-nil.</li> <li>2. The contents of <i>buffer</i> must not be changed until <i>callback</i> has been called.</li> <li>3. If <i>hostspec</i> is a host name (that is a string not specifying an IP address), then <code>async-io-state-send-message-to-address</code> uses the family of the socket to decide whether to look for IPv6 or IPv4 addresses. If <code>async-io-state</code> was created by <code>create-async-io-state</code>, the <i>ipv6</i> argument to <code>create-async-io-state</code> must match the family of the socket for <code>async-io-state-send-message-to-address</code> to work.</li> <li>4. For connected UDP sockets, use <code>async-io-state-send-message</code>.</li> </ol>
Example	<code>(example-edit-file "async-io/udp")</code>

See also      `create-async-io-state-and-connected-udp-socket`  
`async-io-state-receive-message`  
`async-io-state-send-message`  
“The Async-I/O-State API” on page 412

## async-io-state-ssl

*Function*

Summary      Accesses the `SSL` attached to an `async-io-state`.

Package      `comm`

Signature      `async-io-state-ssl async-io-state => ssl-pointer`

Arguments      `async-io-state`      An `async-io-state`.

Values      `ssl-pointer`      A foreign pointer of type `ssl-pointer`, or `nil`.

Description      The function `async-io-state-ssl` accesses the `SSL` that is attached to the `async-io-state` `async-io-state`.  
It returns `nil` if `SSL` is not attached.

See also      `async-io-state`  
`ssl-pointer`

## async-io-state-ssl-side

*Function*

Summary      Accesses the `ssl-side` of an `async-io-state`.

Package      `comm`

Signature      `async-io-state-ssl-side async-io-state => ssl-side`

Arguments      `async-io-state`      An `async-io-state`.

Values	<i>ssl-side</i>	<code>:client, :server, :both or nil</code>
Description	The function <code>async-io-state-ssl-side</code> accesses the ssl-side of the <code>async-io-state</code> <code>async-io-state</code> . It returns <code>nil</code> if SSL is not attached.	
Note	<code>async-io-state-ssl-side</code> is useful as a predicate for testing if an <code>async-io-state</code> has SSL attached.	
See also	<code>async-io-state</code>	

## **async-io-state-write-buffer** *Function*

Summary	Asynchronously writes a buffer to an <code>async-io-state</code> .	
Package	<code>comm</code>	
Signature	<code>async-io-state-write-buffer</code> <code>async-io-state</code> <code>buffer</code> <code>callback</code> <code>&amp;key start end timeout error-callback user-info</code>	
Arguments	<i>async-io-state</i>	An <code>async-io-state</code> .
	<i>buffer</i>	A <code>cl:base-string</code> or an 8-bit <code>cl:simple-array</code> .
	<i>callback</i>	A function designator for a function of 3 arguments.
	<i>start</i>	A lower bounding index designator for <code>buffer</code> .
	<i>end</i>	An upper bounding index designator for <code>buffer</code> .
	<i>timeout</i>	<code>nil</code> or a positive real.
	<i>error-callback</i>	A function designator for a function of 3 arguments, or <code>nil</code> .
	<i>user-info</i>	A Lisp object.

Values	None.
Description	<p>The function <code>async-io-state-write-buffer</code> asynchronously writes the part of buffer <i>buffer</i> between indexes <i>start</i> and <i>end</i> to <code>async-io-state</code>. When this writing has succeeded or the state's <code>async-io-state-write-timeout</code> has passed, <i>callback</i> is called like this:</p> <pre><code>callback async-io-state buffer number-of-bytes-written</code></pre> <p>The default value of <i>start</i> is 0. The default value of <i>end</i> is the length of <i>buffer</i>.</p> <p>If an error occurs during the I/O operation and <code>error-callback</code> is non-nil, then <code>error-callback</code> is called with these same arguments:</p> <pre><code>error-callback async-io-state buffer number-of-bytes-written</code></pre> <p>If <code>error-callback</code> is <code>nil</code>, then <i>callback</i> is called, so it should check for errors using <code>async-io-state-write-status</code>.</p> <p>If the operation does not finish within the state's <code>async-io-state-write-timeout</code> period then the state's <code>async-io-state-write-status</code> is set to <code>:timeout</code> and <i>callback</i> is called.</p> <p>If <code>timeout</code> or <code>user-info</code> are supplied then they set the state's <code>async-io-state-write-timeout</code> and <code>async-io-state-user-info</code> for this and subsequent operations.</p>
See also	<p><code>async-io-state-read-buffer</code>  <code>async-io-state-read-with-checking</code>  “The Async-I/O-State API” on page 412</p>

## async-io-state-user-info

*Accessor*

Summary	Accesses the user info of an <code>async-io-state</code> .
Package	<code>comm</code>

Signature	<code>async-io-state-user-info</code> <code>async-io-state =&gt; user-info</code> <code>setf (async-io-state-user-info</code> <code>async-io-state)</code> <code>user-info</code> <code>=&gt; user-info</code>	
Arguments	<code>async-io-state</code>	An <code>async-io-state</code> .
	<code>user-info</code>	A Lisp object.
Values	<code>user-info</code>	A Lisp object.
Description	The accessor <code>async-io-state-user-info</code> is used to read and write the <code>user-info</code> of <code>async-io-state</code> . LispWorks itself does not use this value for any purpose.	
See also	<code>async-io-state</code> <code>create-async-io-state</code> “The Async-I/O-State API” on page 412	

		<i>Function</i>
	<b>attach-ssl</b>	
Summary	Attaches SSL to a socket stream.	
Package	<code>comm</code>	
Signature	<code>attach-ssl</code> <code>socket-stream &amp;key</code> <code>ssl-ctx</code> <code>ssl-side</code> <code>ctx-configure-callback</code> <code>ssl-configure-callback</code> <code>handshake-timeout</code> <code>tlsext-host-name</code> <code>=&gt; ssl</code>	
Arguments	<code>socket-stream</code>	A <code>socket-stream</code> .
	<code>ssl-ctx</code>	A symbol or a foreign pointer.
	<code>ssl-side</code>	One of the keywords <code>:client</code> , <code>:server</code> or <code>:both</code> .

*ctx-configure-callback*

A function designator or `nil`. The default value is `nil`.

*ssl-configure-callback*

A function designator or `nil`. The default value is `nil`.

*handshake-timeout*

A `real` or `nil` (the default).

*tlsext-host-name* A string or `nil`.

Values      `ssl`      A foreign pointer of type `ssl-pointer`.

Description      The function `attach-ssl` attaches SSL to the socket-stream socket-stream.

The allowed values and meaning of the keyword arguments are as described for `socket-stream`.

Note that `attach-ssl` is used by

`(make-instance 'comm:socket-stream :ssl-ctx ...)`

and by

`(comm:open-tcp-stream ... :ssl-ctx ...)`

but you can also call it explicitly.

Before starting to create objects, `attach-ssl` ensures the SSL library (by calling `ensure-ssl`) and calls `do-rand-seed` to seed the Pseudo Random Number Generator (PRNG), so normally you do not need to worry about these.

`ssl-side`, `ssl-ctx`, `ctx-configure-callback`, `ssl-configure-callback` and `handshake-timeout` are interpreted as described in “Keyword arguments for use with SSL” on page 421. After this, `ssl_set_fd` is used to attach the `SSL` to the socket and this is recorded in the socket stream.

The default value of `ssl-ctx` is `t` and the default value of `ssl-side` is `:server`.

If `tlsext-host-name` is non-nil, then the SNI extension in the SSL connection is set to its value.

When a `socket-stream` is closed, `detach-ssl` is called with `:retry-count nil`, which, if the stream is attached to SSL, calls `ssl_shutdown` and then frees the object (or objects) that were automatically allocated.

If SSL is already attached to `socket-stream` then `attach-ssl` signals an error.

See also      `detach-ssl`

	<i>Function</i>
<b>call-wait-state-collection</b>	
Summary	Calls the functions associated with the active states in a <code>wait-state-collection</code> .
Package	<code>comm</code>
Signature	<code>call-wait-state-collection collection</code>
Arguments	<code>collection</code> A <code>wait-state-collection</code> .
Description	The function <code>call-wait-state-collection</code> calls the functions associated with the active states in <code>collection</code> , and perform any actions requested by messages that arrive from other processes.
Notes	Typically you would not call <code>call-wait-state-collection</code> yourself, but it will be called by <code>loop-processing-wait-state-collection</code> .
See also	<code>create-and-run-wait-state-collection</code> <code>loop-processing-wait-state-collection</code> “The Async-I/O-State API” on page 412

<b>close-accepting-handle</b>	<i>Function</i>
Summary	Closes an accepting handle.
Package	<code>comm</code>
Signature	<code>close-accepting-handle <i>accepting-handle</i> &amp;optional <i>callback</i></code>
Arguments	<p><i>accepting-handle</i> An <code>accepting-handle</code>.</p> <p><i>callback</i> A function designator or <code>nil</code>.</p>
Description	<p>The function <code>close-accepting-handle</code> closes the accepting handle <i>accepting-handle</i>. In particular, it closes the socket which frees up the port that the socket is bound to.</p> <p><i>accepting-handle</i> has to be an accepting handle, currently that means the result of <code>accept-tcp-connections-creating-async-io-states</code>.</p> <p>If <i>callback</i> is non-nil, it must be a function of one argument. <i>callback</i> is called after closing the handle, with the collection which was supplied to <code>accept-tcp-connections-creating-async-io-states</code> which created the handle.</p> <p><code>close-accepting-handle</code> is asynchronous. To do something which is guaranteed to happen after the socket is closed, use <i>callback</i>.</p>
Notes	<i>callback</i> is called on the collection process, so it should not do much work.
See also	<p><code>accepting-handle</code></p> <p><code>accept-tcp-connections-creating-async-io-states</code></p>

	<i>Function</i>				
Summary	Closes an <b>async-io-state</b> and removes it from any internal structures.				
Package	<code>comm</code>				
Signature	<code>close-async-io-state <i>async-io-state</i> &amp;key <i>keep-alive-p</i> =&gt; <i>buffered-data-length</i></code>				
Arguments	<table> <tr> <td><i>async-io-state</i></td><td>An <b>async-io-state</b>.</td></tr> <tr> <td><i>keep-alive-p</i></td><td>A generalized boolean.</td></tr> </table>	<i>async-io-state</i>	An <b>async-io-state</b> .	<i>keep-alive-p</i>	A generalized boolean.
<i>async-io-state</i>	An <b>async-io-state</b> .				
<i>keep-alive-p</i>	A generalized boolean.				
Values	<table> <tr> <td><i>buffered-data-length</i></td><td></td></tr> <tr> <td></td><td>A non-negative integer.</td></tr> </table>	<i>buffered-data-length</i>			A non-negative integer.
<i>buffered-data-length</i>					
	A non-negative integer.				
Description	<p>The function <b>close-async-io-state</b> closes <i>async-io-state</i> and removes it from any internal structures. Once <i>async-io-state</i> has been closed, you cannot perform I/O operations on it.</p> <p>By default, <b>close-async-io-state</b> also closes the <i>object</i> in <i>async-io-state</i> (that is, the argument to <b>create-async-io-state</b>). This closing can be prevented by supplying true for <i>keep-alive-p</i>, so you can perform further I/O operations on that <i>object</i>. In this case you will need to close <i>object</i> later.</p> <p><i>async-io-state</i> may contain some buffered data that it read from the object but did not use yet. The return value is the length of such data and you can use <b>async-io-state-get-buffered-data</b> to get it.</p>				
Notes	If <i>async-io-state</i> is attached to SSL, then it is detached. This occurs even if <i>keep-alive-p</i> is true.				
See also	“The Async-I/O-State API” on page 412				

	<i>Function</i>
Summary	Closes a <code>wait-state-collection</code> and all of its states.
Package	<code>comm</code>
Signature	<code>close-wait-state-collection collection</code>
Arguments	<i>collection</i> A <code>wait-state-collection</code> .
Description	The function <code>close-wait-state-collection</code> closes all of the states in <i>collection</i> . That means that the underlying communication object is closed and the <code>async-io-state</code> objects that are currently associated with <i>collection</i> cannot be used for further I/O and will not receive callbacks anymore.
Notes	<p><code>close-wait-state-collection</code> does not do anything that affects further processing in <i>collection</i>. In particular, you can add new states to the collection afterwards, and waiting and calling, either by <code>loop-processing-wait-state-collection</code> or <code>wait-for-wait-state-collection</code> and <code>call-wait-state-collection</code>, can continue. <code>loop-processing-wait-state-collection</code> does not stop if <code>close-wait-state-collection</code> is called inside it.</p> <p><code>close-wait-state-collection</code> is a "nasty" call, because it just kills any <code>async-io-state</code> associated with the collection. Normally should only be used only when you stop using the collection.</p> <p><code>close-wait-state-collection</code> cannot be called on a collection in parallel to itself or <code>loop-processing-wait-state-collection</code>, <code>wait-for-wait-state-collection</code> or <code>call-wait-state-collection</code>. It can be called inside the scope of <code>call-wait-state-collection</code>, and <code>loop-processing-wait-state-collection</code>.</p>

You can use `apply-in-wait-state-collection-process` to cause execution inside the scope of `call-wait-state-collection`.

See also      `create-and-run-wait-state-collection`  
                 “The Async-I/O-State API” on page 412

	<i>Function</i>
<b>create-and-run-wait-state-collection</b>	
Summary	Creates and runs a <code>wait-state-collection</code> .
Package	<code>comm</code>
Signature	<code>create-and-run-wait-state-collection name &amp;key handler with-backtrace =&gt; wait-state-collection</code>
Arguments	<p><code>name</code>      A Lisp object that names the collection. It is used only for printing.</p> <p><code>handler</code>      <code>nil</code>, <code>t</code>, the keyword <code>:abort</code> or a function.</p> <p><code>with-backtrace</code>      The keyword <code>:bug-form</code>, <code>t</code>, the keyword <code>:quick</code>, or <code>nil</code>.</p>
Values	<p><code>wait-state-collection</code></p> <p>A <code>wait-state-collection</code>.</p>
Description	<p>The function <code>create-and-run-wait-state-collection</code> creates and runs a <code>wait-state-collection</code>.</p> <p><code>create-and-run-wait-state-collection</code> creates a <code>wait-state-collection</code> and then starts a new process which calls <code>loop-processing-wait-state-collection</code> on the new <code>wait-state-collection</code> (and therefore activates it), and returns it as <code>wait-state-collection</code>. The new process has process name "Loop Collection <code>name</code>". When <code>loop-processing-wait-state-collection</code> exits, <code>wait-state-collection</code> is closed and the other process exits too.</p>

You can use `wait-state-collection-stop-loop` to make `loop-processing-wait-state-collection` exit, and hence close `wait-state-collection` and make the process go away. Calling `process-terminate` on the process itself can also be used, because it will use `wait-state-collection-stop-loop`.

`handler` specifies handling of errors that occur on the process in which the collection is run. The values have the following effects:

<code>nil</code>	No handling.
<code>:abort</code>	Abort (calls the function <code>cl:abort</code> ).
<code>t</code>	Print the condition to the standard output, and unless <code>with-backtrace</code> is <code>nil</code> produces a backtrace, and then aborts.
A function	Must be a function of three arguments when <code>with-backtrace</code> is non-nil, or two arguments when <code>with-backtrace</code> is <code>nil</code> . When a serious condition is signaled, the handler is called inside the context of the error (like a handler in <code>cl:handler-bind</code> ).

When `with-backtrace` is non-nil:

`handler object condition backtrace-string`

When `with-backtrace` is `nil`:

`handler object condition`

The `object` argument is the object that is responsible for the error. Currently this is always the `async-io-state` with which the callback that caused the error is associated. If there is an error outside a callback (which should not happen, unless there is a bug), then `object` is `nil`. `condition` is the condition that is signaled. `backtrace-string` is a string which is the result of producing a backtrace. If the handler returns, `(cl:abort)` is called.

*with-backtrace* controls whether a backtrace is produced when *handler* is `t` or a function. It is passed to `output-backtrace` as the first argument. See `output-backtrace` for details.

The default value of *handler* is `nil`. The default value of *with-backtrace* is `:bug-form`.

*wait-state-collection* can be used immediately by passing it to one of the `create-async-io-state*` functions.

#### Notes

1. The `wait-state-collection` *wait-state-collection* does nothing by itself. You need to create and use `async-io-state` objects to actually do something.
2. Aborting by the handler is done by calling `(cl:abort)`, which aborts to the closest enclosing abort restart. If your code establishes such a restart around the error, the aborting will abort to it. Otherwise it will abort back to the loop of waiting and calling.
3. Real applications will probably always pass the handler.
4. While the handler is run, no further processing is done in the collection. Therefore the handler should not do a significant amount of work.

`accept-tcp-connections-creating-async-io-states`

## **create-async-io-state**

## *Function*

Summary      Creates an `async-io-state` for a socket.

Package      `comm`

Signature	<code>create-async-io-state collection object &amp;key read-timeout write-timeout user-info udp ipv6 name queue-output =&gt; async-io- state</code>	
Arguments	<i>collection</i>	A <code>wait-state-collection</code> .
	<i>object</i>	A <code>socket-stream</code> or an integer.
	<i>read-timeout</i>	<code>nil</code> or a positive real.
	<i>write-timeout</i>	<code>nil</code> or a positive real.
	<i>user-info</i>	A Lisp object.
	<i>udp</i>	<code>nil</code> , <code>t</code> , or the keyword <code>:connected</code> .
	<i>ipv6</i>	A boolean.
	<i>name</i>	A Lisp object.
	<i>queue-output</i>	A boolean.
Values	<code>async-io-state</code>	An <code>async-io-state</code> .
Description	<p>The function <code>create-async-io-state</code> creates an <code>async-io-state</code> for the object <i>object</i>. If <i>object</i> is an integer, then it is assumed to be a socket handle (a file descriptor on Unix-like systems). If <i>object</i> is a <code>socket-stream</code>, then the <code>async-io-state</code> contains its socket.</p> <p><i>read-timeout</i>, <i>write-timeout</i> and <i>user-info</i> are set in <code>async-io-state</code> using the corresponding accessors <code>async-io-state-read-timeout</code>, <code>async-io-state-write-timeout</code> and <code>async-io-state-user-info</code>.</p> <p>If <i>udp</i> is non-nil and <i>object</i> is a socket, then this tells <code>create-async-io-state</code> that the socket is a UDP socket (rather than TCP). If <i>udp</i> is <code>:connected</code>, this also tells <code>create-async-io-state</code> that the socket is a connected socket, which affects whether you can use <code>async-io-state-send-message</code> (connected) or <code>async-io-state-send-message-to-address</code> (unconnected). When <i>object</i> is a stream, it is always assumed</p>	

to be a TCP socket, regardless of the value of *udp*. The default value of *udp* is `nil`.

*ipv6* tells `create-async-io-state` whether the socket was made as an IPv6 socket (with `AF_INET6`) or IPv4 (with `AF_INET`). This makes a difference only for unconnected UDP sockets (it tells `async-io-state-send-message-to-address` when called with a host name whether to look for IPv6 or IPv4 addresses).

*queue-output* controls what happens if you try to perform a write operation on the state while another write operation is ongoing. When *queue-output* is `nil` this will cause an error. When *queue-output* is non-nil, the second write operation is queued and actually executed later. The default value of *queue-output* is `nil`.

After calling `create-async-io-state`, *object* should not be used directly for I/O in the same direction (read or write) until `close-async-io-state` has been called.

See also	<code>create-async-io-state-and-connected-tcp-socket</code> <code>accept-tcp-connections-creating-async-io-states</code> “The Async-I/O-State API” on page 412
----------	--

		<i>Function</i>
<b><code>create-async-io-state-and-connected-tcp-socket</code></b>		<i>Function</i>
Summary	Creates an <code>async-io-state</code> which attempts to make a TCP connection.	
Package	<code>comm</code>	
Signature		<code>create-async-io-state-and-connected-tcp-socket collection host service callback &amp;key read-timeout write-timeout user-info connect-timeout local-address local-port keepalive nodelay name queue-output =&gt; async-io-state ssl-ctx ctx-configure-callback ssl- configure-callback handshake-timeout</code>
Arguments	<code>collection</code>	A <code>wait-state-collection</code> .

<i>host</i>	An integer or a string or an <code>ipv6-address</code> object.
<i>service</i>	A string or a fixnum.
<i>callback</i>	A function designator for a function of two arguments.
<i>read-timeout</i>	<code>nil</code> or a positive real.
<i>write-timeout</i>	<code>nil</code> or a positive real.
<i>user-info</i>	A Lisp object.
<i>connect-timeout</i>	<code>nil</code> or a positive real.
<i>local-address</i>	<code>nil</code> , an integer, a string or an <code>ipv6-address</code> object.
<i>local-port</i>	<code>nil</code> , a string or a fixnum.
<i>keepalive</i>	A generalized boolean.
<i>nodelay</i>	A generalized boolean.
<i>queue-output</i>	A boolean.
<i>name</i>	A Lisp object.
<i>ssl-ctx</i>	A symbol or a foreign pointer.
<i>ctx-configure-callback</i>	A function designator or <code>nil</code> . The default value is <code>nil</code> .

<i>ssl-configure-callback</i>	A function designator or <code>nil</code> . The default value is <code>nil</code> .
-------------------------------	---

#### *handshake-timeout*

A `real` or `nil` (the default).

Values	<i>async-io-state</i>	An <code>async-io-state</code> .
--------	-----------------------	----------------------------------

Description	
	The function <code>create-async-io-state-and-connected-tcp-socket</code> creates an <code>async-io-state</code> which attempts to make a TCP connection to <code>host</code> on port <code>service</code> within <code>connect-timeout</code> seconds. <code>host</code> and <code>service</code> are interpreted as described in “Specifying the target for connecting and binding a socket” on page 408.
	When the connection has been made, <code>callback</code> is called with arguments <code>async-io-state</code> and <code>nil</code> . Normally <code>callback</code> will start asynchronous I/O by calling <code>async-io-state-read-buffer</code> , <code>async-io-state-write-buffer</code> or <code>async-io-state-read-with-checking</code> .
	If no connection can be made, <code>callback</code> is called with <code>async-io-state</code> and a list of a format control-string and args, suitable for applying to <code>format</code> . In general, it doesn't make much sense for the callback to call <code>error</code> within <code>callback</code> , so it should report the problem in some way, typically by writing to some log. It may also need to inform the user interactively, but that needs to be done in another process, and is better done by using some kind of end-user dialog rather than invoking <code>error</code> .
	<code>local-address</code> and <code>local-port</code> are used to bind the local side of the socket to a particular address and/or port if non-nil.
	<code>keepalive</code> and <code>nodelay</code> set the SO_KEEPALIVE and TCP_NODELAY in the socket. The default value of <code>keepalive</code> is <code>nil</code> . The default value of <code>nodelay</code> is <code>t</code> .
	<code>queue-output</code> controls what happens if you try to perform a write operation on the state while another write operation is ongoing. When <code>nil</code> , this will cause an error. When non-nil, the second write operation is queued and actually executed later. The default value of <code>queue-output</code> is <code>nil</code> .
	<code>read-timeout</code> , <code>write-timeout</code> , <code>user-info</code> and <code>name</code> are set in <code>async-io-state</code> using the corresponding accessors <code>async-io-state-read-timeout</code> , <code>async-io-state-write-timeout</code> , <code>async-io-state-user-info</code> and <code>async-io-state-name</code> .

The default value of *name* is a string "Connected TCP".

*ssl-ctx*, *ctx-configure-callback*, *ssl-configure-callback* and *hand-shake-timeout* are interpreted as described in "Keyword arguments for use with SSL" on page 421. Unlike the other ways of creating a socket stream with SSL processing, `create-async-io-state-and-connected-tcp-socket` does not take the *ssl-side* argument and always uses the value `:client`.

Once the connection has been made,, you can get the socket by calling `async-io-state-object` on `async-io-state` (see `async-io-state`)

See also      `create-async-io-state`  
                 `accept-tcp-connections-creating-async-io-states`  
                  "The Async-I/O-State API" on page 412

## `create-async-io-state-and-connected-udp-socket`                  *Function*

Summary      Creates an `async-io-state` where the *object* is a connected UDP socket.

Package      `comm`

Signature     `create-async-io-state-and-connected-udp-socket collection hostspec service &key queue-output name errorp ipv6 read-timeout write-timeout user-info local-address local-port => async-io-state`

Arguments    *collection*      A `wait-state-collection` to associate with the result.

*hostspec, service*   Specify the socket address to connect to in the standard way.

*ipv6*               One of `nil`, `t` or the keyword `:any`.

*errorp*              A boolean.

*local-address, local-port*

		Specify the local socket address in the standard way.
	<i>queue-output</i>	A boolean.
	<i>read-timeout</i>	<code>nil</code> or a positive real.
	<i>write-timeout</i>	<code>nil</code> or a positive real.
	<i>user-info</i>	A Lisp object.
	<i>name</i>	A Lisp object.
Values	<code>async-io-state</code>	An <code>async-io-state</code> .
Description		<p>The function <code>create-async-io-state-and-connected-udp-socket</code> creates a new UDP socket, connects it to the socket address specified by <i>hostspec</i> and <i>service</i>, optionally binds it if <i>local-port</i> or <i>local-address</i> are non-<code>nil</code>, and then creates and returns an <code>async-io-state</code> object that can be used to perform I/O operations on the socket. The I/O operations are done using <code>async-io-state-receive-message</code> and <code>async-io-state-send-message</code>.</p> <p><i>hostspec</i> and <i>service</i> are interpreted as described in “Specifying the target for connecting and binding a socket” on page 408.</p> <p><i>local-address</i> and <i>local-port</i> are also interpreted as described in “Specifying the target for connecting and binding a socket” on page 408. Both values can be <code>nil</code>.</p> <p>Connecting the socket affects the destination of messages sent using the <code>async-io-state</code>, and also restricts the origin of received messages.</p> <p>When <i>ipv6</i> is <code>:any</code>, the system selects whether to use an IPv4 or IPv6 socket (normally it will be IPv4). When <i>ipv6</i> is <code>t</code> it forces using IPv6, and <code>nil</code> forces IPv4. The default value of <i>ipv6</i> is <code>:any</code>.</p> <p><i>queue-output</i> controls what happens if you try to perform a write operation on the state while another write operation is</p>

ongoing. When *queue-output* is `nil`, this will cause an error. When *queue-output* is non-`nil`, the second write operation is queued and actually executed later. The default value of *queue-output* is `t`.

*read-timeout*, *write-timeout*, *user-info* and *name* are set in `async-io-state` using the corresponding accessors `async-io-state-read-timeout`, `async-io-state-write-timeout`, `async-io-state-user-info` and `async-io-state-name`.

The default value of *name* is a string "Connected UDP".

When *errorp* is `nil`, `create-async-io-state-and-connected-udp-socket` returns `nil` for run time errors rather than signalling an error. The default value of *errorp* is `t`.

- Notes
1. If you need an unconnected socket, use `create-async-io-state-and-udp-socket`.
  2. The call to `create-async-io-state-and-connected-udp-socket` itself is synchronous.
  3. You cannot use `async-io-state-send-message-to-address` with the result of `create-async-io-state-and-connected-udp-socket` (because the socket address to send to is already specified by connecting.)

- See also
- `async-io-state-receive-message`  
`async-io-state-send-message`  
`create-async-io-state-and-udp-socket`  
“The Async-I/O-State API” on page 412

	<b>Function</b>
<b>create-async-io-state-and-udp-socket</b>	
Summary	Creates an <code>async-io-state</code> where <i>object</i> is an unconnected UDP socket.
Package	<code>comm</code>

Signature	<code>create-async-io-state-and-udp-socket collection &amp;key name errorp ipv6 queue-output read-timeout write-timeout user-info local- address local-port =&gt; result</code>	
Arguments	<code>collection</code>	A <code>wait-state-collection</code> to associate with the returned <code>async-io-state</code> .
	<code>ipv6</code>	One of <code>nil</code> , <code>t</code> , the keyword <code>:any</code> or the keyword <code>:both</code> .
	<code>errorp</code>	A boolean.
	<code>local-address</code> , <code>local-port</code>	Specify the local socket address in the standard way.
	<code>read-timeout</code>	<code>nil</code> or a positive real.
	<code>write-timeout</code>	<code>nil</code> or a positive real.
	<code>user-info</code>	A Lisp object.
	<code>name</code>	A Lisp object.
	<code>queue-output</code>	A boolean.
Values	<code>result</code>	An <code>async-io-state</code> or <code>nil</code> .
Description	<p>The function <code>create-async-io-state-and-udp-socket</code> creates an <code>async-io-state</code> where <i>object</i> is an unconnected UDP socket.</p> <p><code>create-async-io-state-with-udp-socket</code> creates a new UDP socket, optionally binds it if <i>local-port</i> or <i>local-address</i> is non-<code>nil</code>, and then creates and returns an <code>async-io-state</code> object that can be used to perform I/O operations on the socket. The I/O operations are performed using <code>async-io-state-receive-message</code> and <code>async-io-state-send-message-to-address</code>. <i>local-address</i> and <i>local-port</i> specify the local socket address as described in “Specifying the target for connecting and binding a socket” on page 408. Both values can be <code>nil</code>.</p>	

*queue-output* controls what happens if you try to perform a write operation on the state while another write operation is ongoing. When `nil`, this will cause an error. When non-`nil`, the second write operation is queued and actually executed later. The default value of *queue-output* is `t`.

When *ipv6* is `:any`, the system selects whether to use an IPv4 or IPv6 socket (normally it will be IPv4). When *ipv6* is `t` it forces using IPv6, and `nil` forces IPv4. The value `:both` means using IPv6, but also allow receiving messages in IPv4. The default value of *ipv6* is `:any`.

When *errorp* is `nil`, `create-async-io-state-and-udp-socket` returns `nil` for run time errors rather than signalling an error. The default value of *errorp* is `t`.

*read-timeout*, *write-timeout*, *user-info* and *name* are set the new `async-io-state` using the corresponding accessors `async-io-state-read-timeout`, `async-io-state-write-timeout`, `async-io-state-user-info` and `async-io-state-name`.

The default value of *name* is a string "UDP".

## Notes

1. If the socket is used to receive messages from unknown senders (that is as a server), then you need to bind the socket by supplying *local-port*. If the socket is only used to send messages then you do not need to bind it, because the recipient of the messages can find the socket's address if it needs to send a reply. You can supply *local-address* to restrict which connections are allowed.
2. You can find the source address of a message that is received using the result of `create-async-io-state-and-udp-socket` by supplying *needs-address t* to `async-io-state-receive-message`.
3. If you need to connect the socket, use `create-async-io-state-and-connected-udp-socket` instead.

4. The call to `create-async-io-state-and-udp-socket` itself is synchronous.
5. You cannot use `async-io-state-send-message` (without address) with the result of `create-async-io-state-and-udp-socket` (because the socket address to send to must be specified).

Example      `(example-edit-file "async-io/udp")`

See also     `async-io-state-receive-message`  
`async-io-state-send-message-to-address`  
`create-async-io-state-and-connected-udp-socket`  
“The Async-I/O-State API” on page 412

## connect-to-tcp-server *Function*

Summary     Attempts to connect to a socket on a server.

Package     `comm`

Signature    `connect-to-tcp-server hostspec service &key errorp timeout local-address local-port keepalive nodelay ipv6 => handle`

Arguments	<code>hostspec</code>	An integer or a string or an <code>ipv6-address</code> object.
	<code>service</code>	A string or a fixnum.
	<code>errorp</code>	A boolean.
	<code>timeout</code>	A positive number, or <code>nil</code> .
	<code>local-address</code>	<code>nil</code> , an integer, a string or an <code>ipv6-address</code> object.
	<code>local-port</code>	<code>nil</code> , a string or a fixnum.
	<code>keepalive</code>	A generalized boolean.
	<code>nodelay</code>	A generalized boolean.

	<i>ipv6</i>	<code>nil</code> , <code>t</code> or <code>:any</code> .
Values	<i>handle</i>	A handle suitable for a <code>socket-stream</code> or a subclass, or <code>nil</code> .
Description	<p>The function <code>connect-to-tcp-server</code> attempts to connect to a socket on a server and returns a handle for the connection if successful. This handle can then be used as the socket when making a <code>socket-stream</code>.</p> <p>The IP address to connect to is specified by <code>hostspec</code>, and the service to provide is specified by <code>service</code>. These two arguments are interpreted as described in “Specifying the target for connecting and binding a socket” on page 408.</p> <p>If <code>errorp</code> is <code>nil</code>, failure to connect (possibly after <code>timeout</code> seconds) returns <code>nil</code>, otherwise an error is signaled.</p> <p><code>timeout</code> specifies a connection timeout. <code>connect-to-tcp-server</code> waits for at most <code>timeout</code> seconds for the TCP connection to be made. If <code>timeout</code> is <code>nil</code> it waits until the connection attempt succeeds or fails. On failure, <code>connect-to-tcp-server</code> signals an error or returns <code>nil</code> according to the value of <code>errorp</code>. To provide a timeout for reads after the connection is made, see <code>read-timeout</code> in <code>socket-stream</code>. The default value of <code>timeout</code> is <code>nil</code>.</p> <p>If <code>local-address</code> is <code>nil</code> then the operating system chooses the local address of the socket. Otherwise the value is interpreted as for <code>hostspec</code> and specifies the local address of the socket. The default value of <code>local-address</code> is <code>nil</code>.</p> <p>If <code>local-port</code> is <code>nil</code> then the operating system chooses the local port of the socket. Otherwise the string or fixnum value is interpreted as for <code>service</code> and specifies the local port of the socket. The default value of <code>local-port</code> is <code>nil</code>.</p> <p>If <code>keepalive</code> is true, <code>SO_KEEPALIVE</code> is set on the socket. The default value of <code>keepalive</code> is <code>nil</code>.</p>	

If *nodelay* is true, `TCP_NODELAY` is set on the socket. The default value of *nodelay* is t.

*ipv6* specifies the address family to use when *hostspec* is a string. When *ipv6* is :any, `connect-to-tcp-server` uses either of IPv4 or IPv6. When *ipv6* is t, it uses only IPv6 addresses, and when *ipv6* is nil it tries only IPv4. The default value of *ipv6* is :any.

- |       |   |
|-------|---|
| Notes | <ol style="list-style-type: none"> <li>1. On Unix the name of the service can normally be found in <code>/etc/services</code>. If it is not there, the manual entry for services can be used to find it.</li> <li>2. In most situations, <code>open-tcp-stream</code>, which returns a stream rather than a handle, is the more convenient interface. <code>connect-to-tcp-server</code> is useful when want to associate further information with the stream. You can define a subclass of <code>socket-stream</code>, connect using <code>connect-to-tcp-server</code>, and call <code>make-instance</code> with your subclass, passing the <i>handle</i> as the socket.</li> </ol> |

## destroy-ssl

### Function

- |             |  |
|-------------|--|
| Summary     | Frees a <code>ssl</code> .   |
| Package     | <code>comm</code>  |
| Signature   | <code>destroy-ssl ssl-pointer</code>   |
| Arguments   | <code>ssl-pointer</code> A foreign pointer of type <code>ssl-pointer</code> .  |
| Description | The function <code>destroy-ssl</code> frees the <code>ssl</code> pointed to by <code>ssl-pointer</code> and also frees any LispWorks cached values associated with it. |

See also      **ssl-pointer**

**destroy-ssl-ctx**                          *Function*

Summary      Frees a **SSL\_CTX**.

Package      **comm**

Signature      **destroy-ssl-ctx** *ssl-ctx-pointer*

Arguments      *ssl-ctx-pointer*    A foreign pointer of type **ssl-ctx-pointer**.

Description      The function **destroy-ssl-ctx** frees the **SSL\_CTX** pointed to by *ssl-ctx-pointer* and also frees any LispWorks cached values associated with it.

See also      **ssl-ctx-pointer**

**detach-ssl**                          *Function*

Summary      Detaches the SSL from a socket stream.

Package      **comm**

Signature      **detach-ssl** *socket-stream* &**key** *retry-count* *retry-timeout*

Arguments      *socket-stream*    A **socket-stream**.

*retry-count*    A non-negative integer.

*retry-timeout*   A non-negative real.

Description      The function **detach-ssl** detaches the SSL from the socket-stream *socket-stream*. If *socket-stream* is not attached to an SSL, **detach-ssl** just returns immediately. Otherwise, it detaches

the SSL from *socket-stream*, tries to shut down the SSL cleanly, and then frees the objects that were allocated by `attach-ssl`.

*retry-count* specifies how many additional times to call `SSL_shutdown` after the second to attempt to get a successful shutdown. The default value of *retry-count* is 5.

*retry-timeout* specifies the time in seconds to wait between each of the calls to `SSL_shutdown`. If it fails to get a successful shutdown after these attempts, `detach-ssl` signals an error. The default value of *retry-timeout* is 0.1.

Note that the shutdown calls happen after the SSL has been detached from *socket-stream* as far as LispWorks is concerned, so if an error occurs at this point and is aborted, *socket-stream* can be used in `attach-ssl` again (assuming that the peer can cope with this situation).

If *retry-count* is `nil`, `detach-ssl` does not try to get a successful shutdown call. This value is used when the stream is closed, but should not be used normally.

See also      `attach-ssl`

## do-rand-seed

*Function*

Summary      Calls the SSL function `RAND_seed`.

Package      `comm`

Signature      `do-rand-seed`

Arguments      `do-rand-seed` takes no arguments.

Values      `do-rand-seed` returns no values.

Description      The function `do-rand-seed` calls the SSL function `RAND_seed` with some suitable value, which is dependent in a

non-trivial way on the current time, the history of the current process and the history of the machine it is running on.

If the machine that it runs on has the file `/dev/urandom`, `do-rand-seed` does nothing.

See also [attach-ssl](#)

## **ensure-ssl** *Function*

Summary Initializes SSL.

Package `comm`

Signature `ensure-ssl &key library-path already-done`

Arguments `library-path` A string or a list of strings.

`already-done` A generalized boolean.

Description The function `ensure-ssl` initializes SSL. If it was already called in the image, `ensure-ssl` does nothing. Otherwise it loads the library, calls `SSL_library_init`, calls `SSL_load_error_strings` and performs internal initializations.

If `already-done` is true, `ensure-ssl` does only the internal initializations. The default value of `already-done` is `nil`.

If `library-path` is passed, it needs to be either a string, specifying one library, or a list of strings specifying multiple libraries. The default value of `library-path` is platform-specific. The initial default value is described in “How LispWorks locates the OpenSSL libraries” on page 420. This default may be changed by calling `set-ssl-library-path`.

See also [openssl-version](#)  
[set-ssl-library-path](#)

		<i>Function</i>
	<b>get-default-local-ipv6-address</b>	
Summary		Gets the default IPv6 address of the local host.
Package		<code>comm</code>
Signature		<code>get-default-local-ipv6-address =&gt; result</code>
Arguments		None.
Values	<i>result</i>	An <code>ipv6-address</code> object or <code>nil</code> .
Description		The function <code>get-default-local-ipv6-address</code> tries to find the local default IPv6 address and if successful returns it.
See also		<code>ipv6-address</code> <code>get-ip-default-zone-id</code>
	<b>get-host-entry</b>	<i>Function</i>
Summary		Returns address (IPv6 and IPv4) or name information about a given host.
Package		<code>comm</code>
Signature		<code>get-host-entry host &amp;key fields ipv6 v4mapped addrconfig numerichost avoid-reverse-lookup =&gt; field-values</code>
Arguments	<i>host</i>	A number or a string.
	<i>fields</i>	A list of keywords.
	<i>ipv6</i>	<code>nil</code> , <code>t</code> or the keyword <code>:any</code> .
	<i>avoid-reverse-lookup</i>	A generalized boolean.
	<i>v4mapped</i>	A boolean.

	<i>addrconfig</i>	A boolean.
	<i>numerichost</i>	A boolean.
Values	<i>field-values</i>	Values, one for each field.
Description		<p>The function <code>get-host-entry</code> returns address or name information about the given host. By default, it tries to find addresses both of IPv6 and IPv4. It uses whatever host naming services are configured on the current machine. <code>nil</code> is returned if the host is unknown.</p> <p><i>host</i> can be one of the following:</p> <ul style="list-style-type: none"> <li>• a name string, for example "<code>www foobar com</code>"</li> <li>• a dotted inet address string, for example "<code>209.130.14.246</code>"</li> <li>• a integer representing the inet address, for example <code>#xD1820EF6</code></li> </ul> <p><i>fields</i> is a list of keywords describing what information to return for the host. If <code>get-host-entry</code> succeeds, it returns multiple values, one value for each field specified. The following fields are allowed:</p> <ul style="list-style-type: none"> <li><code>:address</code> The primary IP address.</li> <li><code>:ipv6-address</code> The primary IPv6 address.</li> <li><code>:ipv4-address</code> The primary IPv4 address.</li> <li><code>:addresses</code> A list of all the IP addresses.</li> <li><code>:ipv6-addresses</code> A list of all the IPv6 addresses, only.</li> <li><code>:ipv4-addresses</code> A list of all the IPv4 addresses, only.</li> <li><code>:name</code> The primary name as a string.</li> <li><code>:aliases</code> The alias names as a list of strings.</li> </ul>

IPv4 addresses are returned as integers and IPv6 addresses are returned as objects of type `ipv6-address`.

If `ipv6` is `nil` or `t` the search is restricted to one family only IPv4 or IPv6. The default value of `ipv6` is `:any`, meaning that addresses in both families are returned. If the argument `host` is a string, that has a similar effect to using the family-specific keywords, but it may be faster. For example, these two calls returns the same addresses (possibly in a different order):

```
(get-host-entry "hostname"
                :fields '(:ipv6-addresses))

(get-host-entry "hostname"
                :fields '(:addresses) :ipv6 t)
```

If `host` is an address of the other type, that is integer with `ipv6` `t` or `ipv6-address` with `ipv6 nil`, then `get-host-entry` first tries to do a reverse lookup to find the name of the host, and then looks for the values as if it was called with this name as the host.

When `avoid-reverse-lookup` is non-`nil`, `get-host-entry` avoids doing reverse lookup if `host` is a string which specifies a valid address (either IPv6 or IPv4). The default value of `avoid-reverse-lookup` is `nil`, so by default it does the lookup.

The arguments `v4mapped`, `addrconfig` and `numerichost` have an effect only when `host` is a string. They define the flags `AI_V4MAPPED`, `AI_ADDRCONFIG` and `AI_NUMERICHOST` when doing the `getaddrinfo` call.

When `v4mapped` is `t`, the IPv6 addresses contain an IPv4 address mapped to IPv6 (`::ffff:<IPv4>`). The default value of `v4mapped` is `nil`.

When `addrconfig` is `t`, addresses of a family are returned only if the local system is configured to handle them. The default value of `addrconfig` is `nil`.

When `numerichost` is `t`, `host` is assumed to be a numeric address, either IPv4 if dotted notation or IPv6. If it is not,

`get-host-entry` just returns `nil`. Using `numerichost` can speed up `get-host-entry`, because it prevents any DNS lookup. This has an effect only if `avoid-reverse-lookup` is non-`nil`. The default value of `numerichost` is `nil`.

- Notes
1. Although the results of `get-host-entry` are not cached by LispWorks, the Operating System might cache them.
  2. When `get-host-entry` is passed a string specifying an IPv6 address, the address can be followed by '%' character and a scope ID. If the scope ID is a decimal number or a valid interface name on the local system, the resulting address contains the scope ID as a number.

Examples

```
CL-USER 16 > (comm:get-host-entry "www.altavista.com"
                                     :fields '(:address))
3511264349

CL-USER 17 > (comm:get-host-entry 3511264349
                                     :fields '(:name))
"altavista.com"

CL-USER 18 > (comm:get-host-entry "altavista.com"
                                     :fields '(:name
                                               :address
                                               :aliases))
"altavista.com"
3511264349
("www.altavista.com" "www.altavista.com")
```

## get-ip-default-zone-id

## Function

- Summary Gets the default zone ID of the local host.
- Package `comm`
- Signature `get-ip-default-zone-id => result`
- Arguments None.

Values	<i>result</i>	An integer or a string, or <code>nil</code> .
Description	The function <code>get-ip-default-zone-id</code> tries to find the local default zone ID, and if successful returns it as an integer or a string.	
See also	<code>ipv6-address</code> <code>get-default-local-ipv6-address</code>	

## **get-service-entry** *Function*

Summary	Returns information about a service.	
Package	<code>comm</code>	
Signature	<code>get-service-entry service protocol &amp;key fields =&gt; value1, value2, ...</code>	
Arguments	<i>service</i>	An integer or a string.
	<i>protocol</i>	A string or <code>nil</code> .
	<i>fields</i>	A list of keywords specifying which information is required.
Values	<i>value1, value2, ...</i>	Multiple values corresponding to the keywords in <i>fields</i> , as described below.
Description	<p>The function <code>get-service-entry</code> looks up <i>service</i> in the system database. If <i>service</i> is an integer, it is the port number to look up. If <i>service</i> is a string, it is a name to look up (it may be one of the aliases).</p> <p>If <i>protocol</i> is a string, then <code>get-service-entry</code> looks for a system database entry with protocol <i>protocol</i>, otherwise it finds the first entry with any protocol.</p> <p><i>fields</i> specifies which information is returned. When <code>get-service-entry</code> finds an entry, it returns information about it</p>	

as multiple values corresponding to the keywords in *fields*. These keywords can be:

- `:name`      Return the name of the entry.
- `:port`      Return the port number of the entry.
- `:aliases`      Return a list of aliases of the service.
- `:protocol`      Return the protocol of the entry, as lower-case strings like "tcp" or "udp".

If *service* is an integer then the default value of *fields* is `(:name)`. Otherwise the default value of *fields* is `(:port)`.

- Notes
- 1. `get-service-entry` tells you what the host computer knows. The results can be quite different between computers.
  - 2. There can be multiple entries with the same name but different protocols. Many services have entries for both UDP and TCP, normally with the same port number. In many cases the protocol that is selected when you pass *protocol nil* is not the correct protocol to use.

- Examples
- ```
(get-service-entry "smtp" nil) => 25
(get-service-entry 25 nil :fields '(:name :aliases)) =>
"smtp", ("mail")
(get-service-entry "mail" nil) => 25
```

- See also
- "Specifying the target for connecting and binding a socket" on page 408

## get-socket-address

## *Function*

- Summary
- Returns the local address and port number of a given socket.
- Package
- `comm`

|             |                                                                                                            |                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Signature   | <code>get-socket-address socket =&gt; address, port</code>                                                 |                                                                            |
| Arguments   | <code>socket</code>                                                                                        | A socket handle.                                                           |
| Values      | <code>address</code>                                                                                       | The local host address of the socket or <code>nil</code> if not connected. |
|             | <code>port</code>                                                                                          | The local port number of the socket or <code>nil</code> if not connected.  |
| Description | The function <code>get-socket-address</code> returns the local address of a connected socket.              |                                                                            |
| Notes       | Connected sockets have two addresses, local and remote.                                                    |                                                                            |

## get-verification-mode                                  *Function*

Summary      Returns the mode of the SSL.

Package      **comm**

Signature     **get-verification-mode ssl-or-ssl-ctx => result**

Arguments    **ssl-or-ssl-ctx**    A foreign pointer of type **ssl-pointer** or  
**ssl-ctx-pointer**.

Values        **result**        A list of symbols.

Description     The function **get-verification-mode** returns the mode of  
the **ssl-pointer** or **ssl-ctx-pointer** as a list of symbols.  
  
*result* is a list containing zero or more of the symbols **:verify-client-once**, **:verify-peer** and **:fail-if-no-peer-cert**, corresponding to the C constants  
**VERIFY\_CLIENT\_ONCE** **VERIFY\_PEER** and  
**FAIL\_IF\_NO\_PEER\_CERT** respectively.

See also      **set-verification-mode**

## ip-address-string                                  *Function*

Summary      Returns the IP address string for an IP address. This can be  
either a dotted address for an integer representing an IPv4  
address, or an IPv6 address string for **ipv6-address**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Signature   | <code>ip-address-string ip-address =&gt; string-ip-address</code>                                                                                                                                                                                                                                                                                                                                                                                   |
| Arguments   | <code>ip-address</code> An integer or an <code>ipv6-address</code> .                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | <code>string-ip-address</code> A string, either dotted string format for an integer or an IPv6 string for <code>ipv6-address</code> .                                                                                                                                                                                                                                                                                                               |
| Description | <p>The function <code>ip-address-string</code> converts its argument to a string in the standard dotted IP address notation <code>a.b.c.d</code>.</p> <p>The function <code>ip-address-string</code> converts its argument to a string in the standard IP address notation. For an IPv4 address (supplied as an integer) this is the <code>a.b.c.d</code> notation. For IPv6 it is the standard IPv6 address notation (not including scope ID).</p> |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Represents IPv6 addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Package     | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>Objects of type <code>ipv6-address</code> represent an IPv6 address. <code>ipv6-address</code> objects are normally created by <code>get-host-entry</code>. They can also be created by <code>parse-ipv6-address</code>.</p> <p><code>ipv6-address</code> can be used wherever an IP address is needed, most commonly <code>open-tcp-stream</code>.</p> <p><code>ipv6-address</code> may contain a scope ID, which is not really part of the address, but is needed for using local addresses.</p> |

The string representation of an `ipv6-address` can be retrieved by `ip-address-string`. The scope ID can be accessed by `ipv6-address-scope-id`.

## **ipv6-address-p** *Function*

Summary The predicate for objects of type `ipv6-address`.

Package `comm`

Signature `ipv6-address-p object => result`

Arguments `object` A Lisp object.

Values `result` A boolean.

Description The function `ipv6-address-p` is the predicate for whether its argument `object` is of type `ipv6-address`.

See also `ipv6-address`

## **ipv6-address-scope-id** *Function*

Summary Returns the scope ID of an IPv6 address.

Package `comm`

Signature `ipv6-address-scope-id ipv6-address => scope-id`

|             |                                                                                                                                                                                                             |                                      |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Arguments   | <i>ipv6-address</i>                                                                                                                                                                                         | An <code>ipv6-address</code> object. |
| Values      | <i>scope-id</i>                                                                                                                                                                                             | A number or a string.                |
| Description | The function <code>ipv6-address-scope-id</code> returns the scope ID of the IPv6 address <i>ipv6-address</i> .<br><br>Global addresses have scope ID 0.<br><br><i>scope-id</i> may be a string or a number. |                                      |

## **ipv6-address-string** *Function*

|             |                                                                                                          |                                      |
|-------------|----------------------------------------------------------------------------------------------------------|--------------------------------------|
| Summary     | Returns the standard string representation of an IPv6 address.                                           |                                      |
| Package     | <code>comm</code>                                                                                        |                                      |
| Signature   | <code>ipv6-address-string</code>                                                                         | <i>ipv6-address =&gt; string</i>     |
| Arguments   | <i>ipv6-address</i>                                                                                      | An <code>ipv6-address</code> object. |
| Values      | <i>string</i>                                                                                            | A string.                            |
| Description | The function <code>ipv6-address-string</code> returns the standard string representation of the address. |                                      |
| Notes       | The result <i>string</i> does not include the scope ID.                                                  |                                      |

| Package     | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>make-ssl-ctx &amp;key ssl-ctx ssl-side =&gt; ssl-ctx-ptr</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments   | <p><code>ssl-ctx</code> A symbol or a foreign pointer.</p> <p><code>ssl-side</code> One of the keywords <code>:client</code>, <code>:server</code> or <code>:both</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <code>ssl-ctx-ptr</code> A foreign pointer of type <code>ssl-ctx-pointer</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description | <p>The function <code>make-ssl-ctx</code> first calls <code>ensure-ssl</code>, and returns a foreign pointer of type <code>ssl-ctx-pointer</code>.</p> <p>If the value of <code>ssl-ctx</code> is <code>t</code>, <code>:default</code>, <code>:v2</code>, <code>:v3</code>, <code>:v23</code> or <code>:tls-v1</code>, <code>make-ssl-ctx</code> creates a <code>SSL_CTX</code> object and returns a pointer to it.</p> <p>The value of <code>ssl-ctx</code> can also be a foreign pointer of type <code>ssl-ctx-pointer</code>, in which case it is simply returned. If <code>ssl-ctx</code> is a foreign pointer of type <code>ssl-pointer</code>, then <code>make-ssl-ctx</code> signals an error.</p> <p>The meaning of the keyword arguments <code>ssl-ctx</code> and <code>ssl-side</code> is as described for <code>socket-stream</code>. The default value of <code>ssl-ctx</code> is <code>t</code> and the default value of <code>ssl-side</code> is <code>:server</code>.</p> |

| Description | The function <code>loop-processing-wait-state-collection</code> loops processing <code>wait-state-collection</code> .<br><br><code>loop-processing-wait-state-collection</code> loops waiting for any state to be ready (using <code>wait-for-wait-state-collection</code> ) and processes any state that is ready (using <code>call-wait-state-collection</code> ). It establishes restarts that allow aborting back into the loop, and a mechanism that allows <code>wait-state-collection-stop-loop</code> to stop the loop.<br><br>If <code>wait-state-collection-stop-loop</code> is called on the <code>wait-state-collection</code> , which can be from other threads, <code>wait-state-collection-stop-loop</code> stops looping and returns. |
| Notes       | In most cases using <code>create-and-run-wait-state-collection</code> is more convenient.<br><br>There can be only one <code>loop-processing-wait-state-collection</code> on each <code>wait-state-collection</code> at a time. Typically this will occur in a process that is made specifically to run <code>loop-processing-wait-state-collection</code> on the collection.                                                                                                                                                                                                                                                                                                                                                                         |

*ctx-configure-callback*

A function designator or `nil`. The default value is `nil`.

*ssl-configure-callback*

A function designator or `nil`. The default value is `nil`.

*handshake-timeout*

A `real` or `nil` (the default).

*tlsext-host-name* A string, `t` or `nil`.

*local-address* `nil`, an integer, a string or a `ipv6-address` object.

*ipv6* `nil`, `t` or `:any`.

*local-port* `nil`, a string or a fixnum.

*nodelay* A generalized boolean.

*keepalive* A generalized boolean.

Values      *stream*      A `socket-stream`.

Description      The function `open-tcp-stream` attempts to connect to a socket on a server and returns *stream* for the connection if successful.

The IP address to connect to is specified by *hostspec*, and the service to provide is specified by *service*. These two arguments are interpreted as described in “Specifying the target for connecting and binding a socket” on page 408.

The direction of the connection is given by *direction*. Its default value is `:io`. The element type of the connection is determined from *element-type*, and is `base-char` by default.

If *errorp* is `nil`, failure to connect (possibly after *timeout* seconds) returns `nil`, otherwise an error is signaled.

*timeout* specifies a connection timeout. `open-tcp-stream` waits for at most *timeout* seconds for the TCP connection to be made. If *timeout* is `nil` it waits until the connection attempt succeeds or fails. On failure, `open-tcp-stream` signals an error or returns `nil` according to the value of *errorp*. To provide a timeout for reads after the connection is made, see *read-timeout*. The default value of *timeout* is `nil`.

*read-timeout* specifies the read timeout of the stream. If it is `nil` (the default), the stream does not time out during reads, and these may hang. See `socket-stream` for more details. To provide a connection timeout, see *timeout*.

*write-timeout* is similar to *read-timeout*, but for writes. See `socket-stream` for more details.

`ssl-ctx`, `ctx-configure-callback`, `ssl-configure-callback` and `handshake-timeout` are interpreted as described in “Keyword arguments for use with SSL” on page 421. Unlike the other ways of creating a socket stream with SSL processing, `open-tcp-stream` does not take the `ssl-side` argument and always uses the value `:client`.

If `tlsext-host-name` is a string, then the SNI extension in the SSL connection to set to its value. If `tlsext-host-name` is `t` and `hostspec` is a string, then the SNI extension in the SSL connection to set to `hostspec`.

If `local-address` is `nil` then the operating system chooses the local address of the socket. Otherwise the value is interpreted as for `hostspec` and specifies the local address of the socket. The default value of `local-address` is `nil`.

If `local-port` is `nil` then the operating system chooses the local port of the socket. Otherwise the string or fixnum value is interpreted as for `service` and specifies the local port of the socket. The default value of `local-port` is `nil`.

`ipv6` specifies the address family to use when `hostspec` is a string. When `ipv6` is `:any`, `open-tcp-stream` uses either of IPv4 or IPv6. When `ipv6` is `t`, it uses only IPv6 addresses, and

when `ipv6` is `nil` it tries only IPv4. The default value of `ipv6` is `:any`.

If `keepalive` is true, `SO_KEEPALIVE` is set on the socket. The default value of `keepalive` is `nil`.

If `nodelay` is true, `TCP_NODELAY` is set on the socket. The default value of `nodelay` is `t`.

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes   | <ol style="list-style-type: none"><li>1. On Unix the name of the service can normally be found in <code>/etc/services</code>. If it is not there, the manual entry for services can be used to find it.</li><li>2. If <code>switch-open-tcp-stream-with-ssl-to-java</code> was called with its argument on non-nil or not supplied, when <code>SSL-CTX</code> is non-nil open-tcp-stream uses Java sockets instead of ordinary sockets. This is the default behavior on Android, because OpenSSL is not available on Android. The resulting streams have some limitations, most importantly <code>c1:listen</code> is not reliable on them. They also verify the host, which ordinary sockets do not currently do, in the same way that the default in <code>open-tcp-stream-using-java</code> does. See “Socket streams with Java sockets and SSL on Android” on page 432 for a full description, and <code>open-tcp-stream-using-java</code> for details about verification and which keywords are used.</li></ol> |
| Example | The following example opens an HTTP connection to a given host, and retrieves the root page:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Description | The function <code>open-tcp-stream-using-java</code> opens a TCP stream using Java sockets for communication. |                                                                                                                                |

**Note:** `open-tcp-stream-using-java` does not have any clear advantage over `open-tcp-stream`. Use it only when you really need it.

`open-tcp-stream-using-java` accepts the same arguments as `open-tcp-stream`, plus `factory` and `verify`, but ignores the values of `write-timeout`, `ipv6`, `ctx-configure-callback`, `ssl-configure-callback` and `tlsext-host-name`. It also treats `ssl-ctx` as a generalized boolean, where any non-nil value means using SSL Java object.

`open-tcp-stream-using-java` opens and returns a `socket-stream` like `open-tcp-stream`, but the socket object that it uses is a Java object. However, `c1:listen` is unreliable on such streams, and they cannot be used in `wait-for-input-streams`. See “Socket streams with Java sockets and SSL on Android” on page 432 for details.

The keyword argument `factory` can be used to specify the socket factory to use to create the Java socket. When passed, it must be a Java socket factory, that is a `jobject` which is an instance of class `javax.net.SocketFactory`. In this case the socket is generated from this factory, the factory determines whether it is a SSL socket or not, and the value of `ssl-ctx` is used only to decide whether to do a handshake. By default, the default factory (the result of `"getDefault"`) of `javax.net.SocketFactory` (when `ssl-ctx` is nil) or `javax.net.ssl.SSLSocketFactory` (when `ssl-ctx` is non-nil) is used.

The keyword argument `verify` is used only when `ssl-ctx` is non-nil. It controls verification of `hostspec` when SSL is used, which means checking that the certificate that was returned by the server is for this server. The default value `t` means using `SSLCertificateSocketFactory` on Android when `factory` is not supplied (see below), on other platforms it is the same as `:strict`. `:strict` mean uses the strict verifier (Java class `org.apache.http.conn.ssl.StrictHostnameVerifier`). `:browser-compat` means using "browser compatible"

verifier (Java class `org.apache.http.conn.ssl.BrowserCompatHostnameVerifier`). Verification with `:browser-compat` is a little more relaxed than with `:strict`.

On Android when `verify` is `t` and `factory` is `nil`, the code uses the socket factory `android.net.SSLCertificateSocketFactory` (instead of the default of `javax.net.ssl.SSLSocketFactory`), which is doing the verification itself. When `factory` is non-`nil`, Android does the same as in the previous paragraph (`verify` using the strict verifier). The `SSLCertificateSocketFactory` has the advantage that it uses SNI (Server Name Indication), which makes verification work better.

When `verify` is a string, it has to be the hostname to use for verification, instead of the `hostspec` argument. The verification is done using the strict verifier.

When `verify` is a `jobject`, it must be a verifier (of class `javax.net.ssl.HostnameVerifier`), and it is used as-is.

The verifier classes above are part of `httpclient` from `apache.org`, and therefore to use them (which is the default when using SSL), you need to have `httpclient`. On Android it is always available, so it is not an issue, on another architectures it needs to be added to the class path.

When `verify` is `nil`, the `hostspec` is not verified, which is not recommended. However, there are valid sites which will fail verification, because they return a certificate for the wrong site (that happens due to use of virtual hosts). At the time of writing, "`gmail.com`" is one of them, and returns a certificate for "`mail.google.com`". However, if the client uses SNI, which is used by Java socket in Java 1.7 or higher, this server does return the correct certificate, and in general all servers should work when using SNI. On Android the default setting uses the `SSLCertificateSocketFactory` (discussed above), which is using SNI. Thus there is a problem only when using Java 1.6 or earlier, and for Android only when you use your

own factory. For these cases, you can either use `verify nil`, or pass the name in the certificate as the `verify` argument:

```
(comm:open-tcp-stream-using-java "gmail.com" 443 :ssl-  
ctx t :verify "mail.google.com")
```

Note however that this will fail if SNI is used.

Notes

1. The Java virtual machine (JVM) must be running for `open-tcp-stream-using-java` to work. On Android the JVM always runs, on other architectures it needs to have been started by `init-java-interface`. When using `ssl-ctx`, `httpclient` must be available too, and again it is always available on Android.
2. On Android, or if you call `switch-open-tcp-stream-with-ssl-to-java`, `open-tcp-stream` uses Java objects for SSL streams. The result of `open-tcp-stream` and `open-tcp-stream-using-java` with `ssl-ctx` non-nil is identical in this case.
3. Using Java sockets was added mainly for SSL streams on Android. It may be useful in other circumstances.
4. You can also make a `socket-stream` with a Java socket by passing the Java socket that your code has created to `(make-instance 'socket-stream ...)`. Note that closing such a stream will close the socket, and if you want to avoid that you need to use `replace-socket-stream-socket`.

| Description | <p>The function <code>parse-ipv6-address</code> parses its argument string as an IPv6 address if possible, otherwise it returns <code>nil</code>. <i>start</i> and <i>end</i> specify the subsequence of <i>string</i> to parse. The default value of <i>start</i> is 0. The default value of <i>end</i> is <code>nil</code>, meaning the length of <i>string</i>.</p> <p><i>trim-whitespace</i> is a boolean specifying that leading and trailing whitespace characters may be ignored. Note that the address itself must not contain any whitespace. The default value of <i>trim-whitespace</i> is <code>t</code>.</p> <p>The address has to be in either standard IPv6 address notation, or dotted-quad notation. It can have the standard simplifications.</p> <p>In addition, the address may be followed by a '%' character and a scope ID. If the scope ID is a string of decimal characters, it is read as a decimal number, otherwise it is taken as-is. The address may also be followed by a '/' and a prefix length in decimal format. The result <code>ipv6-address</code> object remembers the prefix length and prints it when the object is printed, but it does not affect the address otherwise.</p> <p>If the syntax of the string <i>string</i> is correct, <code>parse-ipv6-address</code> constructs the <code>ipv6-address</code> object and returns it. It does not perform any address resolution.</p> |                                                           |

| <i>callback</i>      | A function designator, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                      |           |                 |                        |                    |                                 |                 |                                              |               |                        |
| <i>errorp</i>        | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |           |                 |                        |                    |                                 |                 |                                              |               |                        |
| Values               | <i>result</i> A foreign pointer or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                      |           |                 |                        |                    |                                 |                 |                                              |               |                        |
| Description          | <p>The function <code>pem-read</code> is an interface to the <code>PEM_read_bio_*</code> set of functions. See the manual entry for <code>pem</code> for specifications of these functions.</p> <p><i>thing-to-read</i> defines which function is required. <code>pem-read</code> concatenates <i>thing-to-read</i> with the string " <code>PEM_read_bio_</code>" to form the name of the <code>pem</code> function to call.</p> <p><i>filename</i> specifies the file to load.</p> <p>If <i>pass-phrase</i> is non-nil, it must be a string, which is passed to the <code>pem</code> function. The default value of <i>pass-phrase</i> is <code>nil</code>.</p> <p>If <i>callback</i> is non-nil, it must be a function with signature:</p> <pre><code>callback <i>maximum-length</i> <i>rwflag</i> =&gt; <i>pass-phrase</i></code></pre> <p>where <i>maximum-length</i> is an integer, <i>rwflag</i> is a boolean and <i>pass-phrase</i> is the pass-phrase to use. The default value of <i>callback</i> is <code>nil</code>, but you cannot pass non-nil values for both <i>pass-phrase</i> and <i>callback</i>.</p> |                      |           |                 |                        |                    |                                 |                 |                                              |               |                        |

If it succeeds, `pem-read` returns a foreign pointer to the structure that was returned by the `pem` function. If `pem-read` fails, if `errorp` is non-nil it signals an error, otherwise it returns `nil`. The default value of `errorp` is `nil`.

## **read-dhparams** *Function*

**Summary**     Reads or uses cached SSL DH parameters.

**Package**     `comm`

**Signature**     `read-dhparams filename &key pass-phrase callback errorp force => dh-ptr`

**Arguments**     `filename`         A pathname designator.

`pass-phrase`     A string, or `nil`.

`callback`      A function designator, or `nil`.

`errorp`        A generalized boolean.

`force`         A generalized boolean.

**Values**        `dh-ptr`      A foreign pointer or `nil`.

**Description**     The function `read-dhparams` reads or uses cached DH parameters.

`filename` specifies the file to check.

Unless `force` is true, `read-dhparams` checks whether the file `filename` has already been loaded, and if it has been loaded, uses the cached value.

If `force` is true, or if there is no cached value for `filename`, `read-dhparams` loads the file by calling `pem-read` with `thing-to-read` argument "DHparams", `pass-phrase`, `callback` and `errorp`. `read-dhparams` caches and returns a foreign pointer to the

resulting DH structure (that is, a pointer corresponding to the C type `DH*`).

If `read-dhparams` fails to load the file `filename`, if `errorp` is true it signals an error, otherwise it returns `nil`. The default value of `errorp` is `t`.

## **replace-socket-stream-socket** *Function*

**Summary**      Replaces the socket in a `socket-stream`, returning the existing socket object without closing it.

**Package**      `comm`

**Signature**      `replace-socket-stream-socket socket-stream socket => socket-or-nil`

**Arguments**      `socket-stream`    A `socket-stream`.

`socket`            A socket object or `nil`.

**Values**            `socket-or-nil`    A socket object or `nil`.

**Description**      The function `replace-socket-stream-socket` replaces the socket in the `socket-stream` `socket-stream`, returning the existing socket object without closing it.

A socket object is normally a socket in the native operating system sense (an integer representing an `fd` socket on Unix, and an integer representing `SOCKET` on Microsoft Windows), but when using the Java interface it can also be a Java socket (`jobject` of class `java.net.Socket`).

`replace-socket-stream-socket` sets the socket in `socket-stream` to the argument `socket`, and then returns the old socket object without closing it.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <ol style="list-style-type: none"> <li>1. Getting the old socket using the <code>socket-stream</code> accessor <code>socket-stream-socket</code> and then using <code>(setf socket-stream-socket)</code> to set the new one is different, because the <code>cl:setf</code> will close the old socket.</li> <li>2. Passing <code>nil</code> as the socket allows you to close the stream while retaining the socket.</li> <li>3. The new socket does not need to be the same kind of socket as the old one.</li> </ol> |

| Description | <p>The function <code>server-terminate</code> terminates a server process. If <code>process</code> is a process object it must be the result of a call to <code>start-up-server</code>. <code>server-terminate</code> terminates it, and frees all the associated resources.</p> <p>If <code>process</code> is <code>nil</code> or is not supplied, the call to <code>server-terminate</code> must be inside the scope of the process that was created by <code>start-up-server</code>, which can be either <i>function</i> or <i>announce</i> that you passed to <code>start-up-server</code>. <code>server-terminate</code> returns <code>t</code> in this case, and the actual termination happens after your function (that is, <i>function</i> or <i>announce</i>) returns.</p> |                                                        |

**server-terminate** returns **t** if the server was still active when it was called, otherwise it returns **nil**. It can be called repeatedly on the same server, and can be used as a predicate to check whether the server really went away.

|          |                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | In LispWorks 6.0 and earlier versions, <b>process-kill</b> is the way to terminate servers. This is deprecated, because it may leave some value in an invalid state. |

cation failure. If no server certificate is sent because an anonymous cipher is used, verification is ignored.

A list      The list contains keywords as described above for *ssl-side :server*.

If non-nil *callback* should be a symbol, function, string or foreign pointer designating a foreign function that is called to perform verification. The default value of *callback* is **nil**.

## **set-ssl-ctx-dh** *Function*

Summary      Sets the DH parameters for a **SSL\_CTX**.

Package      **comm**

Signature      **set-ssl-ctx-dh ssl-ctx &key dh filename func filename-list pass-phrase callback => result**

Arguments      **ssl-ctx**      A foreign pointer.  
**filename**      A pathname designator or **nil**.  
**func**      A function designator or **nil**.  
**filename-list**      An association list.  
**pass-phrase**      A string, or **nil**.  
**callback**      A function designator, or **nil**.

Values      **result**      A boolean.

Description      The function **set-ssl-ctx-dh** sets the DH parameters for a **SSL\_CTX**.

*ssl-ctx* can be either a foreign pointer of type **ssl-ctx-pointer** or a foreign pointer of type **ssl-pointer**.

The value is to use is specified by one of the parameters *dh*, *filename*, *func* or *filename-list*.

If *dh* is non-nil, it must be a foreign pointer to a DH (corresponding to the C type `DH*`), and this DH is used as-is. The default value of *dh* is `nil`.

Otherwise, if *filename* is non-nil, it must be a pathname designator for a file containing DH parameters, which is loaded (by `read-dhparams`) and then used. In this case, *pass-phrase* and *callback* can be used, and are passed to `pem-read`.

Otherwise, if *func* is non-nil, it must be a function with signature:

`func is-export keylength => dh-ptr`

where *is-export* is a boolean, *keylength* is an integer, and *dh-ptr* is a pointer to an appropriate DH structure. `set-ssl-ctx-dh` installs *func* as the DH callback.

Otherwise (that is, if each of *dh*, *filename* and *func* are `nil`) then *filename-list* must be a non-nil association list of keylengths and filenames, sorted by the keylengths in ascending order (that is, larger keylengths are towards the end of the list). `set-ssl-ctx-dh` installs a DH callback which when called finds the first keylength which is equal or bigger than the required keylength, loads the associated file (by calling `read-dhparams`), and returns it. It also loads the first file of the list immediately.

*result* is `t` on success, `nil` otherwise.

| Description                |                                              | The function <code>set-ssl-ctx-options</code> sets the options in a <code>SSL_CTX</code> .<br><br><code>ssl-ctx</code> can be either a foreign pointer of type <code>SSL_CTX-pointer</code> or a foreign pointer of type <code>SSL-pointer</code> .<br><br>The option that is set is the <code>logior</code> of all the options that are passed to <code>set-ssl-ctx-options</code> via the keyword arguments. The value used for each non-nil keyword <code>keyword</code> is the value of <code>SSL_OP_keyword</code> . The meaning of the options is specified in the OpenSSL manual page for <code>SSL_set_options</code> . |

| <i>ssl-ctx</i>  | A foreign pointer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                    |                 |                                              |                 |                                 |
| <i>callback</i> | A function designator, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                    |                 |                                              |                 |                                 |
| <i>password</i> | A string, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                    |                 |                                              |                 |                                 |
| Description     | <p>The function <code>set-ssl-ctx-password-callback</code> sets the password for a <code>SSL_CTX</code>, either to a callback or a password. <code>ssl-ctx</code> should be a foreign pointer of type <code>ssl-ctx-pointer</code>. If <code>callback</code> is non-<code>nil</code>, it must be a function with signature:</p> $\text{callback } \text{maximum-length } \text{rwflag} \Rightarrow \text{result}$ <p>where <code>maximum-length</code> is an integer, <code>rwflag</code> is a boolean and <code>result</code> is a string. The default value of <code>callback</code> is <code>nil</code>. If <code>password</code> is non-<code>nil</code> and <code>callback</code> is <code>nil</code>, a callback is installed that simply returns <code>password</code>. The default value of <code>password</code> is <code>nil</code>. If both <code>callback</code> and <code>password</code> are <code>nil</code>, <code>set-ssl-ctx-password-callback</code> signals an error.</p> |                |                    |                 |                                              |                 |                                 |
| See also        | <code>ssl-ctx-pointer</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                    |                 |                                              |                 |                                 |

|           | <i>Function</i>                                    |
|-----------|----------------------------------------------------|
| Summary   | Sets the SSL library path.                         |
| Package   | <code>comm</code>                                  |
| Signature | <code>set-ssl-library-path library-path</code>     |
| Arguments | <i>library-path</i> A string or a list of strings. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>set-ssl-library-path</code> sets the SSL library path.</p> <p><i>library-path</i> should be a string or a list of strings. Each string specifies a library to load. The libraries are loaded in the order they are in the list.</p> <p>Note that in contrast to <code>ensure-ssl</code>, the effect of <code>set-ssl-library-path</code> persists after saving and restarting the image.</p> |
| See also    | <p><code>ensure-ssl</code><br/> “How LispWorks locates the OpenSSL libraries” on page 420</p>                                                                                                                                                                                                                                                                                                                      |

## socket-error *Class*

| Description | <p>The class <code>socket-stream</code> implements a buffered stream connected to a socket. The socket handle, specified by <code>:socket</code>, and the direction, specified by <code>:direction</code>, must be passed for a meaningful stream to be constructed. Common Lisp input functions such as <code>read-char</code> will see <code>end-of-file</code> if the other end of the socket is closed.</p> <p>The <code>:element-type</code> initarg determines the expected element type of the stream traffic. However, stream input and output functions for character and binary data generally work in the</p> |

obvious way on a `socket-stream` with any of the allowed values of `element-type`. For example, `read-sequence` can be called with a string buffer and a binary `socket-stream`: the character data is constructed from the input as if by `code-char`. Similarly `write-sequence` can be called with a string buffer and a binary `socket-stream`: the output is converted from the character data as if by `char-code`. Also, 8-bit binary data can be read and written to a `base-char socket-stream`.

All standard stream I/O functions except for `write-byte` and `read-byte` have this flexibility.

The `:read-timeout` initarg specifies the read timeout in seconds, or is `nil`, meaning there are no timeouts during reads (this is the default).

The `read-timeout` property is intended for use when a socket connection might hang during a call to any Common Lisp input function. The `read-timeout` can be set by `make-instance` or by `open-tcp-stream`. It can also be modified by `(setf stream:stream-read-timeout)`. When `read-timeout` is `nil`, there is no timeout during reads and the call may hang. When `read-timeout` is not `nil`, and there is no input from the socket for more than `read-timeout` seconds, any reading function returns `end-of-file`. The `read-timeout` does not limit the time inside `read`, but the time between successful extractions of data from the socket. Therefore, if the reading needs several rounds it may take longer than `read-timeout`.

Using `(setf stream:stream-read-timeout)` on the stream while it is inside a read function has undefined effects. However, the `setf` function can be used between calls to read functions. The `read-timeout` property of a stream can be read by  
`(stream:stream-read-timeout stream)`

The `:write-timeout` initarg specifies the write timeout in seconds, or is `nil`, meaning that there are no timeouts during writes (this is the default).

The `write-timeout` property is similar to `read-timeout`, but for write operations. If flushing the stream buffer takes too long then `error` is called.

The initargs `:ssl-ctx`, `:ssl-side`, `:ctx-configure-callback`, `:ssl-configure-callback` and `:handshake-timeout` can be supplied to create and configure socket streams with SSL processing. See “Keyword arguments for use with SSL” on page 421 for more details.

If `:tlsext-host-name` initarg is a string then the SNI extension in the SSL connection to set to its value.

If there is a non-local exit while initializing the `socket-stream` (the most common reason being a SSL handshake failure when using SSL), then the stream will be closed. This will cause the socket to be closed as well.

## Notes

1. The function `wait-for-input-streams` and `wait-for-input-streams-returning-first` are a convenient interface for waiting for input from socket streams. The standard I/O functions (`c1:read`, `c1:read-char` and so on) can also wait properly. You can also use `process-wait` and similar functions with `c1:listen` in the `wait-function`, but you will need to use `with-noticed-socket-stream`.
2. The socket object in a `socket-stream` is normally a socket object in the operating system sense. On Unix and Microsoft Windows it is an integer corresponding to a socket as returned from the C functions `socket` and `accept`. It can also be a Java socket object, see “Socket streams with Java sockets and SSL on Android” on page 432 for details.
3. `(setf socket-stream-socket)` can be used to set the socket object in the stream, and can also set it to `nil`. When there is already a socket in the stream, `(setf socket-stream-socket)` closes it before setting the slot to

the new socket. The function `replace-socket-stream-socket` can be used to set the socket without closing the old one.

**Example**

The following makes a bidirectional stream connected to a socket specified by `handle`.

```
(make-instance 'comm:socket-stream
               :socket handle
               :direction :io
               :element-type 'base-char)
```

This example creates a socket stream with a read-timeout:

```
(make-instance 'comm:socket-stream
               :handle handle
               :direction :input
               :read-timeout 42)
```

The following form illustrates character I/O in a binary `socket-stream`:

```
(with-open-stream (x
                  (comm:open-tcp-stream
                   "localhost" 80
                   :element-type '(unsigned-byte 8)))
  (write-sequence (format nil "GET / HTTP/1.0~%~%") x)
  (force-output x)
  (let ((res (make-array 20 :element-type 'base-char)))
    (values (read-sequence res x) res)))
```

The following form illustrates binary I/O in a `base-char socket-stream`:

```

(with-open-stream (x
  (comm:open-tcp-stream
    "localhost" 80
    :element-type 'base-char))
  (write-sequence
    (map 'simple-array (unsigned-byte 8) 1)
    'char-code
    (format nil "GET / HTTP/1.0~%~%"))
  x)
  (force-output x)
  (let ((res (make-array 20
    :element-type
    '(unsigned-byte 8))))
    (values (read-sequence res x)
      (map 'string 'code-char res))))
```

|-----------|---------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Summary   | Returns the local address and port number of a given socket stream. |                                                                                   |
| Package   | <code>comm</code>                                                   |                                                                                   |
| Signature | <code>socket-stream-address stream =&gt; address, port</code>       |                                                                                   |
| Arguments | <code>stream</code>                                                 | A socket stream.                                                                  |
| Values    | <code>address</code>                                                | The local host address of the socket stream or <code>nil</code> if not connected. |
|           | <code>port</code>                                                   | The local port number of the socket stream or <code>nil</code> if not connected.  |

|             |                                                                                            |
|-------------|--------------------------------------------------------------------------------------------|
| Description | The function <b>socket-stream-address</b> returns the local address of a connected socket. |
| Notes       | Connected socket streams have two addresses, local and remote,                             |
| See also    | <b>socket-stream-peer-address</b><br><b>get-socket-address</b>                             |

## **socket-stream-ctx** *Function*

|             |                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Accesses the <b>ssl_ctx</b> attached to a socket stream.                                                                                                                                         |
| Package     | <b>comm</b>                                                                                                                                                                                      |
| Signature   | <b>socket-stream-ctx</b> <i>socket-stream</i> => <b>ssl-ctx-pointer</b>                                                                                                                          |
| Arguments   | <i>socket-stream</i> A <b>socket-stream</b> .                                                                                                                                                    |
| Values      | <i>ssl-ctx-pointer</i> A foreign pointer of type <b>ssl-ctx-pointer</b> , or <b>nil</b> .                                                                                                        |
| Description | <p>The function <b>socket-stream-ctx</b> accesses the <b>ssl_ctx</b> that is attached to the <b>socket-stream</b> <i>socket-stream</i>.</p> <p>It returns <b>nil</b> if SSL is not attached.</p> |
| See also    | <b>socket-stream</b><br><b>ssl-ctx-pointer</b>                                                                                                                                                   |

## **socket-stream-handshake** *Function*

|         |                                      |
|---------|--------------------------------------|
| Summary | Perform a SSL handshake on a stream. |
| Package | <b>comm</b>                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Signature   | <code>socket-stream-handshake stream &amp;optional timeout =&gt; success</code>                                                                                                                                                                                                                                                                                                                                                                     |                                |
| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                 | A <code>socket-stream</code> . |
|             | <code>timeout</code>                                                                                                                                                                                                                                                                                                                                                                                                                                | <code>nil</code> or a real.    |
| Values      | <code>success</code>                                                                                                                                                                                                                                                                                                                                                                                                                                | A boolean.                     |
| Description | <p>The function <code>socket-stream-handshake</code> performs a handshake on <code>stream</code>, which must be attached to SSL.</p> <p><code>socket-stream-handshake</code> returns false if the handshake does not finish in <code>timeout</code> seconds or if the SSL connection was cleanly closed by the other side. Other failures cause an error to be signaled.</p> <p><code>socket-stream-handshake</code> returns true on success.</p>   |                                |
| Notes       | <p>The other <code>socket-stream</code> interface functions signal errors if the handshake fail for any reason, including timeout or clean close.</p> <p>If SSL was attached with <code>ssl-side :both</code>, then you will need to specify which side to take in the handshake by calling <code>ssl-set-accept-state</code> or <code>ssl-set-connect-state</code> with the <code>ssl-pointer</code> return by <code>socket-stream-ssl</code>.</p> |                                |

|             | <i>abort</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A generalized boolean.                                |
| Description | <p>The function <b>socket-stream-shutdown</b> performs a shutdown on one or both sides of a TCP socket connection of <i>stream</i>, which can indicate to the peer that no more data will be sent or received.</p> <p>When <i>direction</i> is <b>:input</b>, receive operations are shut down.<br/>       When <i>direction</i> is <b>:output</b>, send operations are shut down.<br/>       When <i>direction</i> is <b>:io</b>, all operations are shut down.</p> |                                                       |

If *abort* is true and *direction* is `:output` or `:io`, then any input or output in the socket stream buffers is discarded. Otherwise output is flushed and input is left in the buffer.

It is an error to read from *stream* (after no data is left in the buffer) after shutdown for `:input` or `:io` or to write to *stream* after shutdown for `:output` or `:io`.

|          |                                                                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>socket-stream-shutdown</code> does not close the socket stream, so it is still necessary to call <code>close</code> to free resources associated with the stream. |

|              |                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | The class for SSL errors corresponding to <code>SSL_ERROR_ZERO_RETURN</code> .                                                          |
| Package      | <code>comm</code>                                                                                                                       |
| Superclasses | <code>ssl-condition</code>                                                                                                              |
| Description  | The condition class <code>ssl-closed</code> corresponds to <code>SSL_ERROR_ZERO_RETURN</code> . It means the underlying socket is dead. |

## **ssl-condition** *Class*

|              |                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------|
| Summary      | The condition class for SSL errors.                                                                           |
| Package      | <code>comm</code>                                                                                             |
| Superclasses | <code>socket-error</code>                                                                                     |
| Subclasses   | <code>ssl-closed</code><br><code>ssl-error</code><br><code>ssl-failure</code><br><code>ssl-x509-lookup</code> |
| Description  | The condition class for errors inside SSL.                                                                    |

| <b>ssl-ctx-pointer</b> | <i>FLI type descriptor</i>                                                                                                                                                                            |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                | An FLI type for use with SSL.                                                                                                                                                                         |
| Package                | <code>comm</code>                                                                                                                                                                                     |
| Signature              | <code>ssl-ctx-pointer</code>                                                                                                                                                                          |
| Description            | The FLI type <code>ssl-ctx-pointer</code> corresponds to the C type <code>SSL_CTX*</code> .                                                                                                           |
| <b>ssl-error</b>       | <i>Class</i>                                                                                                                                                                                          |
| Summary                | The class for SSL errors corresponding to <code>SSL_ERROR_SYSCALL</code> .                                                                                                                            |
| Package                | <code>comm</code>                                                                                                                                                                                     |
| Superclasses           | <code>ssl-condition</code>                                                                                                                                                                            |
| Description            | The condition class <code>ssl-error</code> corresponds to <code>SSL_ERROR_SYSCALL</code> . It means that something got broken.                                                                        |
| <b>ssl-failure</b>     | <i>Class</i>                                                                                                                                                                                          |
| Summary                | The class for SSL errors corresponding to <code>SSL_ERROR_SSL</code> .                                                                                                                                |
| Package                | <code>comm</code>                                                                                                                                                                                     |
| Superclasses           | <code>ssl-condition</code>                                                                                                                                                                            |
| Description            | The condition class <code>ssl-failure</code> corresponds to <code>SSL_ERROR_SSL</code> . This means a failure in processing the input, typically due to a mismatch between the client and the server. |

You get this error when trying to use a SSL connection to a non-secure peer.

## **ssl-new** *Function*

|             |                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Creates a <code>SSL</code> .                                                                                                                                                          |
| Package     | <code>comm</code>                                                                                                                                                                     |
| Signature   | <code>ssl-new ssl-ctx-pointer =&gt; ssl-pointer</code>                                                                                                                                |
| Arguments   | <code>ssl-ctx-pointer</code> A foreign pointer of type <code>ssl-ctx-pointer</code> .                                                                                                 |
| Values      | <code>ssl-pointer</code> A foreign pointer of type <code>ssl-pointer</code> .                                                                                                         |
| Description | <p>The function <code>ssl-new</code> creates a <code>SSL</code> by a direct call to the C function <code>SSL_new</code>.</p> <p>It returns a pointer to the new <code>SSL</code>.</p> |
| See also    | <code>ssl-ctx-pointer</code><br><code>ssl-pointer</code>                                                                                                                              |

## **ssl-pointer** *FLI type descriptor*

|             |                                                                                     |
|-------------|-------------------------------------------------------------------------------------|
| Summary     | An FLI type for use with SSL.                                                       |
| Package     | <code>comm</code>                                                                   |
| Signature   | <code>ssl-pointer</code>                                                            |
| Description | The FLI type <code>ssl-pointer</code> corresponds to the C type <code>SSL*</code> . |

## ssl-x509-lookup

*Class*

|              |                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | The class for SSL errors corresponding to <code>SSL_ERROR_WANT_X509_LOOKUP</code> .                                                                                     |
| Package      | <code>comm</code>                                                                                                                                                       |
| Superclasses | <code>ssl-condition</code>                                                                                                                                              |
| Description  | The condition class <code>ssl-x509-lookup</code> corresponds to <code>SSL_ERROR_WANT_X509_LOOKUP</code> . It happens when a certificate is rejected by a user callback. |

## start-up-server

*Function*

|           |                                                                                                                                                                             |                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|

|             | <i>startup-condition</i> | A condition object, or nil.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description |                          | <p>The function <code>start-up-server</code> starts a TCP server. Use <code>open-tcp-stream</code> to send messages from another client to the server.</p> <p>The <i>function</i> argument provides the name of the function that processes connections. When a connection is made <i>function</i> is called with the connected socket handle, at which point you can make a stream using <code>make-instance</code> and communicate with the client. The server does not accept more connections until <i>function</i> returns, so normally it should create another light-weight process to handle the connection. However, the operating system typically provides a small queue of partially accepted connections, which prevents connection failure for new clients until the server is ready to accept more connections. If <i>function</i> is not specified the built-in Lisp listener server is used. See the examples section below.</p> <p>If <i>announce</i> is a stream or t (denoting <code>*standard-output*</code>), a message appears on the stream when the server is started.</p> <p>If <i>announce</i> is a function it is called when the server is started. <i>announce</i> should take two arguments: <i>socket</i> and <i>condition</i>. <i>socket</i> is the socket used by the server: <i>announce</i> can therefore be used to record this socket. <i>condition</i> describes the error if there is one. <i>announce</i> can be called with <i>socket</i> nil and a condition only if <i>error</i> is nil. If the process is killed, <i>announce</i> is called with <i>socket</i> nil and <i>condition</i> nil.</p> <p>The default for <i>announce</i> is nil, meaning there is no message.</p> |

*service* is interpreted as described in “Specifying the target for connecting and binding a socket” on page 408. The default value of *service* is a string “`lispworks`”.

*backlog* specifies the maximum number of pending connections for the socket in the operating system (see your operating system’s documentation for the function `listen`). The default value of *backlog* is 5.

If *local-address* is `nil` then the server will receive connections to all IP addresses on the computer. If *local-address* is non-`nil` then the server only receives connections for the IP address that *local-address* specifies. The default value of *local-address* is `nil`.

*address* also determines which family is used when making the socket. `AF_INET6` is used in these cases:

- The address is an `ipv6-address`.
- The address is a string specifying an IPv6 address.
- The address is a string that resolves to an IPv6 address.

Otherwise `AF_INET` is used. When *address* is not supplied, `AF_INET` is used. To open a server with `AF_INET6` listening to any address, either use the keyword argument `ipv6` or pass the zero IPv6 address “`::`”.

If *keepalive* is true, `SO_KEEPALIVE` is set on the socket. The default value of *keepalive* is `nil`.

If *nodelay* is true, `TCP_NODELAY` is set on the socket. The default value of *nodelay* is `t`.

The *process-name* specifies the process name. The default is constructed from the service name in the following fashion:

```
(format nil "~S server" service)
```

The *wait* argument controls whether `start-up-server` waits for the server to start or returns immediately. When *wait* is non-`nil` and an error was signaled, *process* is `nil` and the error is returned in *startup-condition*. Otherwise just one

value, the server process, is returned. The default for `wait` is `nil`.

`ipv6` affects the resolution of `address` if it is a string or `nil`. When `ipv6` is `nil`, it forces IPv4 addresses, and if `ipv6` is `t` it forces IPv6 addresses. When `ipv6` is `:any` the system tries either IPv4 or IPv6 and uses the first socket that it succeeds to bind. When `ipv6` is `:both` the system uses IPv6 (like the value `t`) but allows connection requests in IPv4. Note that with `t` only IPv6 connections are allowed. The default value of `ipv6` is `:any`.

The `error` argument controls what happens if an error is signaled in the server thread. If `error` is `nil` then the thread is terminated. If `error` is non-nil then the debugger is entered. The default value for `error` is (`not wait`).

#### Notes

1. Some versions of Microsoft Windows fail to detect the case where more than one server binds a given port, so an error will not be raised in this situation.
2. When the server is not needed any more, terminate it by calling `server-terminate` with the `process` returned by `start-up-server` as its argument, or call `server-terminate` from the `function` supplied to `start-up-server`.
3. When using using `ipv6 t`, it is possible to listen separately for IPv4 connections on the same service (by another service or using the Asynchronous I/O API). When using `:both`, it is not possible to listen separately to IPv4 on the same service.
4. The server has a mechanism that checks for repeated unexplained failures associated with accepting sockets, and if that happens too often it closes the accepting socket and opens it again. When that happens, `announce` is called again with the same arguments. If `service` was `nil`, the port that the underlying system assigned to the first socket is used for opening the socket again. One situation

that invokes that mechanism is putting an iOS device to sleep, which causes the accepting socket to become broken in a non-obvious way.

**Compatibility note** In LispWorks 6.1 and previous versions, the argument *ipv6 t* means either accepting IPv4 or not, depending on the default of the operating system. In LispWorks 7.0 and later *ipv6 t* means never allow IPv4 connections.

**Examples** The following example uses the built-in Lisp listener server:

```
(comm:start-up-server :service 10243)
```

It makes a Lisp listener server on port 10243 (check with local network managers that this port number is safe to use). When a client connects to this, Lisp calls `read`. The client should send a string using Common Lisp syntax followed by a newline. This string is used to name a new light-weight process that runs a Lisp listener. When this has been created, the server waits for more connections.

The next example illustrates the use of the *function* argument. For each line of input read by the server it writes the line back with a message. The stream generates `EOF` if the other end closes the connection.

```
(defvar *talk-port* 10244) ; a free TCP port number

(defun make-stream-and-talk (handle)
  (let ((stream (make-instance 'comm:socket-stream
                               :socket handle
                               :direction :io
                               :element-type
                               'base-char)))
    (mp:process-run-function (format nil "talk ~D"
                                      handle)
                             '()
                             'talk-on-stream stream)))
```

```

(defun talk-on-stream (stream)
  (unwind-protect
    (loop for line = (read-line stream nil nil)
          while line
          do
            (format stream "You sent: '~A'~%" line)
            (force-output stream))
    (close stream)))

(comm:start-up-server :function 'make-stream-and-talk
                      :service *talk-port*)

```

This is a client which uses the talk server:

```

(defun talking-to-myself ()
  (with-open-stream
    (talk (comm:open-tcp-stream "localhost"
                                *talk-port*))
    (dolist (monolog
              '("Hello self."
                "Why don't you say something original?"
                "Talk to you later then. Bye."))
      (write-line monolog talk)
      (force-output talk)
      (format t "I said: \"~A\"~%"
              monolog)
      (format t "Self replied: \"~A\"~%"
              (read-line talk nil nil)))))

(talking-to-myself)
=>
I said: "Hello self."
Self replied: "You sent: 'Hello self.'"
I said: "Why don't you say something original?"
Self replied: "You sent: 'Why don't you say something
original?'"
I said: "Talk to you later then. Bye."
Self replied: "You sent: 'Talk to you later then.
Bye.'"

```

This example illustrates a server which picks a free port and records the socket. The last form queries the socket for the port used.

```
(defvar *my-socket* nil)

(defun my-announce-function (socket condition)
  (if socket
      (setf *my-socket* socket)
      (my-log-error condition)))

(comm:start-up-server :service nil
                      :error nil
                      :announce 'my-announce-function)

(multiple-value-bind (address port)
    (comm:get-socket-address *my-socket*)
  port)
```

|           | <code>announce</code>      | An output stream, <code>t</code> , <code>nil</code> or a function. |
|           | <code>service</code>       | An integer, a string or <code>nil</code> .                         |
|           | <code>local-address</code> | An integer, a string or <code>nil</code> .                         |
|           | <code>address</code>       | A synonym for <code>local-address</code> .                         |
|           | <code>process-name</code>  | A symbol or expression.                                            |

Description      The function `start-up-server-and-mp` starts multiprocess-ing if it has not already been started and then calls `start-up-server` with the supplied `function`, `announce`, `service`, `local-address` and `process-name` arguments.

Notes            **start-up-server-and-mp** is not implemented on Microsoft Windows.

## **string-ip-address** *Function*

Summary        Returns either an integer representing an IPv4 address or an **ipv6-address** object from the given IP address string.

Package        **comm**

Signature      **string-ip-address** *ip-address-string* => *ip-address*

Arguments      *ip-address-string* A string denoting an IP address in either dotted format for IPv4 or standard IPv6 format.

Values          *ip-address*        Either an integer representing an IPv4 address, or an **ipv6-address** object.

Description      The function **string-ip-address** takes a string in the standard dotted IP address notation **a.b.c.d** and returns the corresponding integer IP address.

The function **string-ip-address** takes a string and tries to parse as an IP address. If *ip-address-string* is in a proper dotted IP address format, it returns an integer representing an IPv4 address. Otherwise it tries to read it as an IPv6 address using **parse-ipv6-address** (with *trim-whitespace-p nil*), which returns an **ipv6-address** object if it is successful or **nil** if it fails.

| Summary     | Make <code>open-tcp-stream</code> use Java sockets for SSL streams.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Package     | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Signature   | <code>switch-open-tcp-stream-with-ssl-to-java &amp;optional on</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Arguments   | <code>on</code> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>The function <code>switch-open-tcp-stream-with-ssl-to-java</code> makes <code>open-tcp-stream</code> use Java sockets for SSL streams.</p> <p>The default state corresponds to <code>on</code> being <code>nil</code>, except on Android when <code>switch-open-tcp-stream-with-ssl-to-java</code> is called before delivering to Android (if the module "comm" was loaded) to switch the state to <code>t</code>. The default value of <code>on</code> is <code>t</code>.</p> <p>Once the state switches to <code>t</code>, when <code>open-tcp-stream</code> is called with <code>ssl-ctx</code> non-<code>nil</code>, it uses a Java socket instead of ordinary socket to implement the stream. The resulting stream has some limitations, in particular <code>c1:listen</code> does not work reliably on it. See "Socket streams with Java sockets and SSL on Android" on page 432 for details.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. The Java virtual machine (JVM) must be running for <code>open-tcp-stream</code> to work after it is switched to use Java sockets. On Android the JVM always runs, on other architectures it needs to have been started by <code>init-java-interface</code>.</li> <li>2. <code>open-tcp-stream-using-java</code> can be used to make plain (non-SSL) socket streams with Java sockets, if that seems to be useful.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Summary     | Waits for a state in a collection to become active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Package     | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Signature   | <code>wait-for-wait-state-collection <i>collection</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments   | <code><i>collection</i></code> A <code>wait-state-collection</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | The function <code>wait-for-wait-state-collection</code> waits for one of the states in <code>collection</code> to become active, or until some message arrives from another process. Such messages may be a result of creating a new <code>async-io-state</code> associated with the collection, or a result of a call to <code>apply-in-wait-state-collection-process.wait-for-wait-state-collection</code> . <code>wait-for-wait-state-collection</code> returns once any of the states in <code>collection</code> is ready or there is a message.                                                                                                                                             |
| Notes       | <p>Typically you would not call <code>wait-for-wait-state-collection</code> yourself, but it will be called by <code>loop-processing-wait-state-collection</code>. However, sometimes you may want to create the looping code yourself. In the latter case, once <code>wait-for-wait-state-collection</code> returns, you will need to call <code>call-wait-state-collection</code> to handle the active states or messages in <code>collection</code>.</p> <p>You can use <code>apply-in-wait-state-collection-process</code> with a function that does nothing (e.g. <code>false</code>) to wake up a waiting call to <code>wait-for-wait-state-collection</code> on a specific collection.</p> |

## **wait-state-collection** *Class*

Summary      An object that controls asynchronous I/O via an event loop.

Package      `comm`

Superclasses      None

Subclasses      None

Description      Objects of class `wait-state-collection` control asynchronous I/O via an event loop.

See also      “The Async-I/O-State API” on page 412

## **wait-state-collection-stop-loop** *Function*

Summary      Stops a loop which is processing a `wait-state-collection`.

Package      `comm`

Signature      `wait-state-collection-stop-loop wait-state-collection`

Arguments      `wait-state-collection`  
                  A `wait-state-collection`.

Description      The function `wait-state-collection-stop-loop` stops a loop which is processing `wait-state-collection`.

If there is currently a call to `loop-processing-wait-state-collection` with the `wait-state-collection`, `wait-state-collection-stop-loop` makes it stop and return.

Notes      `wait-state-collection-stop-loop` can be called from any process.

## with-noticed-socket-stream *Macro*

Package     `comm`

Signature    `with-noticed-socket-stream (stream) &body body`

Arguments    `stream`      A stream created using `open-tcp-stream`.

`body`        Code to be executed while the stream is “noticed”.

Description    The macro `with-noticed-socket-stream` evaluates the `body` forms with the stream `stream` “noticed” for input. `stream` becomes unnoticed afterwards.

The macro is designed to be used with streams created by `open-tcp-stream`.

Notes        1. You do not normally need to use this macro, because all of the standard functions that read from socket streams (`read-char` and so on) will do this automatically when necessary. However, if you call `process-wait` yourself with a `wait-function` that detects new input from a socket stream, then this macro is necessary to cause LispWorks to evaluate the `wait-function` when there is input on the underlying socket. Without that, there might be a delay before the thread responds to the input.

2. `with-noticed-socket-stream` is not implemented on the Windows platform.

# The COMMON-LISP Package

This chapter describes the LispWorks extensions to symbols in the **COMMON-LISP** package, which is used by default. This chapter notes only those differences between LispWorks and the ANSI Common Lisp standard.

You should refer to this standard for full documentation about standard Common Lisp symbols. An HTML version, the Common Lisp HyperSpec, is available in the LispWorks IDE via the menu command **Help > Manuals > ANSI Common Lisp Standard**.

| Arguments | <i>string</i>        | A string designator.                                                                                  |
|           | <i>package</i>       | A package designator or <code>nil</code> .                                                            |
|           | <i>external-only</i> | A generalized boolean.                                                                                |

|             |                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>apropos</code> behaves as specified in ANSI Common Lisp. There is an additional optional argument <code>external-only</code> , which if true restricts the search to symbols which are external in the searched package or packages. The default value of <code>external-only</code> is <code>nil</code> . |

| Method signatures | <code>close :around (stream buffered-stream) &amp;key abort</code><br><code>close (stream buffered-stream) &amp;key abort</code> |
| Arguments         | <code>stream</code> A stream.<br><code>abort</code> A generalized boolean.                                                       |
| Values            | <code>result</code> A boolean.                                                                                                   |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The standard function <code>close</code> is implemented as a generic function. All external resources used by the stream should be freed and true returned when that has been done. The result value for <code>close</code> is as per the Common Lisp ANSI specification.</p> <p>When <code>stream</code> is an instance of a subclass of <code>buffered-stream</code>, if <code>abort</code> is true then any remaining data in the buffer can be discarded. There are two built-in methods on <code>buffered-stream</code>. The primary method specialized on <code>buffered-stream</code> returns <code>t</code>. The other, an around method specialized on <code>buffered-stream</code>, checks whether the stream is closed, and if it is does nothing, including not calling the next method, which means not doing any of the primary, before and after methods. If the stream is opened, it flushes the stream buffer if <code>abort</code> is <code>nil</code>, calls the next method and marks the stream as closed if that method returns true. Thus the only requirement for a primary method specialized on a subclass of <code>buffered-stream</code> is that it must close any underlying data source and return true.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. You should not define an around method on a subclass of <code>buffered-stream</code>, as that will happen around the around method on <code>buffered-stream</code>. Use before and after methods instead.</li> <li>2. The <code>close</code> method on the <code>fundamental-stream</code> class sets a flag for <code>open-stream-p</code></li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Description             | <p><code>compile</code> calls the compiler to translate a lambda expression into a code vector containing an equivalent sequence of host specific machine code. A compiled function typically runs between 10 and 100 times faster. It is generally worth compiling the most frequently called Lisp functions in a large application during the development phase. The compiler detects a</p> |                   |                                                |                         |                                    |

large number of programming errors, and the resulting code runs sufficiently faster to justify the compilation time, even during development.

Warning messages are printed to `*error-output*`. Other messages are printed to `*standard-output*`.

`definition` and the return values are as specified for Common Lisp. Note that `name` may be a list not of the form `(setf symbol)`, which is an extension to Common Lisp.

`compile` also supports a LispWorks-specific extension allowing `compile` to compile an arbitrary form. When `definition` is not supplied and `name` is a list not of the form `(setf symbol)`, `compile` compiles it as if by `compile-file` but without any file related processing and does it in-memory, so it has also the same effect as loading. This has a similar effect to compiling a definition in the LispWorks Editor tool, except that there is no source recording. Multiple forms can be compiled in one call by wrapping them with `progn`. When `compile` is used this way it always returns `nil`.

**Notes** A compiled function object may be returned. Such compiled function objects are not printable (but see `disassemble`) other than as `#<Function FOO hex-address>`.

**Compatibility notes** In LispWorks 5.1 and previous versions, warning messages are printed to `*standard-output*`.

**Examples**

```
(defun fn (...) ...) ; interpreted definition for fn

(compile 'fn) ; replace with compiled
; definition

(compile nil '(lambda (x) (* x x)))
; returns compiled squaring function

(compile 'cube '(lambda (x) (* x x x)))
; defun and compile in one
```

## **compile-file** *Function*

**Summary** Compiles a Lisp source file into a form that both loads and runs faster.

**Package** `common-lisp`

**Signature** `compile-file input-file &key output-file verbose print external-format load => output-truename, warnings-p, failure-p`

|                  |                        |                                                             |
|------------------|------------------------|-------------------------------------------------------------|
| <b>Arguments</b> | <i>input-file</i>      | A pathname designator.                                      |
|                  | <i>output-file</i>     | A pathname designator, or <code>:temp</code> .              |
|                  | <i>verbose</i>         | A generalized boolean.                                      |
|                  | <i>print</i>           | A generalized boolean.                                      |
|                  | <i>external-format</i> | An external format specification.                           |
|                  | <i>load</i>            | A generalized boolean or the keyword <code>:delete</code> . |

**Values** *output-truename* A pathname or `nil`.

*warnings-p* A generalized boolean.

*failure-p* A generalized boolean.

**Description** The function `compile-file` calls the compiler to translate a Lisp source file into a form that both loads and runs faster. A compiled function typically runs more than ten times faster than when interpreted (assuming that it is not spending most

of its work calling already compiled functions). A source file with a `.lisp` or `.lsp` extension compiles to produce a file with a `.fasl` extension (the actual extension depends on the host machine CPU and the LispWorks implementation). Subsequent use of `load` loads the compiled version (which is in LispWorks's FASL or Fast Load format) in preference to the source.

In compiling a file the compiler has to both compile each function and top level form in the file, and to produce the appropriate FASL directives so that loading has the desired effect. In particular objects need to have space allocated for them, and top level forms are called as they are loaded.

*output-file* specifies the location of the output file, relative to the current directory (not the path of the file). If it specifies a directory, then the output file is placed there instead of the same directory as the source. If it contains a file name but not a file type, then the platform specific file type is added and the result specifies the full path of the output file. If *output-file* has a type, it specifies the full path of the output file. Note that in this case when you want to load the file you will need to add the type to `*binary-file-types*`. See the example below.

The special value *output-file* :`temp` offers a convenient way to specify that the output file is a temporary file in a location that is likely to be writable.

*verbose* controls the printing of messages describing the file being compiled, the current optimization settings, and other information. If *verbose* is `nil`, there are no messages. If *verbose* is `0`, only the "Compiling file..." message is printed. For all other true values of *verbose*, messages are also printed about:

- compiler optimization settings before the file is processed, and
- multiple matches when *input-file* does not specify the pathname type, and

- any clean down (garbage collection) that occurs during the compilation.

The default value is the value of `*compile-verbose*`, which defaults to `t`.

`print` controls the printing of information about the compilation. It can have the following values. If `print` is `nil`, no information is printed. If `print` is a non-positive number, then only warnings are printed. If `print` is a positive number no greater than 1, or if `print` is any non-number object, then the information printed consists of all warning messages and one line of information per function that is compiled. If `print` is a number greater than 1, then full information is printed. The default value of `print` is the value of `*compile-print*`, which has the default value 1.

Warning messages are printed to `*error-output*`. Other messages are printed to `*standard-output*`.

`external-format` is interpreted as for `open`. The default value is `:default`.

If `load` is true, then the file is loaded after compilation. If `load` is the special value `:delete` then the compiled file is deleted after loading it. The source file is not affected. This is especially useful when using `output-file :temp`, to avoid leaving compiled files.

`output-truename` is the `truename` of the output file, or `nil` if that cannot be created.

`warnings-p` is `nil` if no conditions of type `error` or `warning` were detected during compilation. Otherwise `warnings-p` is a list containing the conditions.

`failure-p` is `nil` if no conditions of type `error` or `warning` (other than `style-warning`) were detected by the compiler, and `t` otherwise.

|                     |                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------|
| Compatibility notes | In LispWorks 5.1 and previous versions, warning messages are printed to <code>*standard-output*</code> . |
|---------------------|----------------------------------------------------------------------------------------------------------|

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Examples | <pre>(compile-file "devel/fred.lisp") ; compile fred.lisp to fred.fasl (compile-file "devel/fred") ; does the same thing  (compile-file "test" :load t) ; compile test.lisp, then load if successful  (compile-file "program" :output-file "program.abc") ; compile "program.lisp" to "program.abc"  (push "abc" sys:*binary-file-types*) ; tells LispWorks that files with extension ; ".abc" are binaries</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Notes    | <p>See <code>declare</code> for a list of the declarations that alter the behavior of the compiler.</p> <p>The act of compiling a file should have no side effects, other than the creation of symbols and packages as the input file is read by the reader.</p> <p>By default a form is skipped if an error occurs during compilation. If you need to debug an error during compilation by <code>compile-file</code>, set <code>*compiler-break-on-error*</code>.</p> <p>During compilation of a file <code>foo.lisp</code> (on an Intel Macintosh, for example) a temporary output file named <code>t_foo.xfasl</code> is used, so that an unsuccessful compile does not overwrite an existing <code>foo.xfasl</code>.</p> <p>LispWorks uses the following naming conventions for fasl files, and it is recommended that you should use them too, to ensure correct operation of <code>load</code> and so on.</p> |

Table 33.1 Naming conventions for FASL files

| Machine/Implementation       | Fasl Extension |
|------------------------------|----------------|
| x86 Windows/32-bit LispWorks | .ofasl         |
| x64 Windows/64-bit LispWorks | .64ofasl       |

Table 33.1 Naming conventions for FASL files

| Machine/Implementation              | Fasl Extension |
|-------------------------------------|----------------|
| x86 Linux/32-bit LispWorks          | .ufasl         |
| amd64 Linux/64-bit LispWorks        | .64ufasl       |
| ARM Linux/32-bit LispWorks          | .rfasl         |
| ARM Linux/64-bit LispWorks          | .64rfasl       |
| x86 FreeBSD/32-bit LispWorks        | .ffasl         |
| amd64 FreeBSD/64-bit LispWorks      | .64ffasl       |
| AIX PowerPC/32-bit LispWorks        | .ifasl         |
| AIX PowerPC/64-bit LispWorks        | .64ifasl       |
| SPARC/32-bit LispWorks              | .wfasl         |
| SPARC/64-bit LispWorks              | .64wfasl       |
| x86 Solaris/32-bit LispWorks        | .sfasl         |
| amd64 Solaris/64-bit LispWorks      | .64sfasl       |
| Intel Macintosh/32-bit LispWorks    | .xfasl         |
| Intel Macintosh/64-bit LispWorks    | .64xfasl       |
| LispWorks for iOS Runtime simulator | .xcfasl        |
| LispWorks for iOS Runtime           | .rfasl         |
| LispWorks for Android Runtime       | .rfasl         |

You can find the fasl file extension appropriate for your machine by looking at the variable `*binary-file-type*`. The variable `*binary-file-types*` contains a list of all the file extensions currently recognized by `load`, `require` and `load-data-file` (in addition to `*binary-file-type*`).

Compatibility notes

1. In LispWorks for Windows 4.4 and previous versions, the fasl file extension is `.fsl`. This changed in LispWorks 5.0.

2. In LispWorks for Linux 4.4 and previous versions, the fasl file extension is `.ufs1`. This changed in LispWorks 5.0.

**concatenate** *Function*

|             |                                                                                                                                                                                                                                                   |  |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Extends the standard <code>concatenate</code> function allowing it to take any Common Lisp type.                                                                                                                                                  |  |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                          |  |
| Signature   | <code>concatenate result-type &amp;rest sequences =&gt; result-sequence</code>                                                                                                                                                                    |  |
| Arguments   | <code>result-type</code> A type specifier.<br><code>sequences</code> A sequence.                                                                                                                                                                  |  |
| Values      | <code>result-sequence</code> A sequence.                                                                                                                                                                                                          |  |
| Description | The function <code>concatenate</code> has been extended to take any Common Lisp type. The <code>result-sequence</code> will be of type <code>result-type</code> unless this is not possible, in which case a <code>type-error</code> is signaled. |  |
| See also    | <code>coerce</code>                                                                                                                                                                                                                               |  |

**declaim** *Macro*

|         |                                       |
|---------|---------------------------------------|
| Summary | Established a specified declarations. |
| Package | <code>common-lisp</code>              |

|             |                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>declare &amp;rest declarations</code>                                                                                                                                                                                                                                                                             |
| Arguments   | <i>declarations</i> Declaration forms.                                                                                                                                                                                                                                                                                  |
| Description | The macro <code>declare</code> behaves as specified in the ANSI Common Lisp Standard with one exception: for a top-level call to <code>declare</code> , optimize declarations are omitted from the compiled binary file. This is useful because you are unlikely to want to change these settings outside of that file. |

| <b>declare</b> |                                                                                                                                                                                                                                                                                                                                                                                                                           | <i>Special Form</i>                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Summary        | Declares a variable as special, provides advice to the Common Lisp system, or helps the programmer to optimize code.                                                                                                                                                                                                                                                                                                      |                                         |
| Package        | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                  |                                         |
| Signature      | <code>declare declaration*</code>                                                                                                                                                                                                                                                                                                                                                                                         |                                         |
| Arguments      | <i>declaration</i>                                                                                                                                                                                                                                                                                                                                                                                                        | A declaration specifier, not evaluated. |
| Values         | <p>The special form <code>declare</code> behaves computationally as if it is not present (other than to affect the semantics), and is only allowed in certain contexts, such as after the variable list in a <code>let</code>, <code>do</code>, <code>defun</code> and so on.</p> <p>(Consult the syntax definition of each special form to see if it takes <code>declare</code> forms and/or documentation strings.)</p> |                                         |
| Description    | There are three distinct uses of <code>declare</code> : one is to declare Lisp variables as “special” (this affects the semantics of the appropriate bindings of the variables), the second is to pro-                                                                                                                                                                                                                    |                                         |

vide advice to help the Common Lisp system (in reality the compiler) run your Lisp code faster or with more sophisticated debugging options, and the third (using the `:explain` declaration) is to help you optimize your code.

If you use `declare` to specify types (and so eliminate type-checking for the specified symbols) and then supply the wrong type, you may obtain a “Segmentation Violation”. You can check this by interpreting the code (rather than compiling it).

The `declare` special form can be used as documented in the Common Lisp HyperSpec as well as with the following extensions:

- `hcl:special-global` declares that the symbol is never bound.

In SMP LispWorks the compiler signals error if it detects that a symbol declared as `hcl:special-global` is bound, and at run time it also signals an error.

In non-SMP LispWorks the compiler gives an error, but there is no run time check. The run time behavior is the same as `c1:special`, with all accesses to the symbol in low safety.

`hcl:special-global` is very useful, and because of the checks it is reasonably safe. It is useful not only for speed, but also to guard against unintentionally binding variables that should not be bound.

See also `defglobal-parameter`.

- `hcl:special-dynamic` declares that the symbol is never accessed outside the dynamic scope of the binding.

In high safety code accessing the symbol outside the scope of binding signals an error. In low safety code it may result in unpredictable behavior.

In non-SMP LispWorks the only effect of this declaration is to make all access to the variable low safety.

`hcl:special-dynamic` is useful, but because it can lead to unpredictable behavior you need to ensure that you test your program in high safety when you use it.

- `hcl:special-fast-access` declares that a symbol should be "fast access".

The semantics of the declaration is the same as `c1:special`, except that access to the variable is low safety. In addition, the compiler compiles access to the symbol in a way that speeds up the access, but also introduces a tiny reduction in the speed of the whole system. The balance between these effects is not obvious.

It is not obvious where `hcl:special-fast-access` is useful. If you can ensure that the symbol is always bound or never bound then `hcl:special-dynamic` or `hcl:special-global` are certainly better.

- `hcl:lambda-list` specifies the value to be returned when a programmer asks for the arglist of a function.
- `values` specifies the value to be returned when you ask for a description of the results of a function.
- `hcl:invisible-frame` specifies that calls to this function should not appear in a debugger backtrace.
- `hcl:alias` specifies that calls to this function should be displayed as calls to an alternative function in a debugger backtrace.
- `hcl:lambda-name` declares the name of the surrounding lambda.
- `:explain` controls messages printed by the compiler while it is processing forms.

You can also use `define-declaration` to add your own declarations, which do not affect compilation but are useful for code walkers.

Description of **hcl:lambda-name** This section documents the **hcl:lambda-name** declaration, which declares the name of the surrounding lambda. This declaration is useful only for a lambda that becomes a standalone function, that is lambda forms that are passed to **function**.

The dspec of the function that is returned by **function** is specified by the second element in the declaration. In the special case when the second element is a two-element list starting with the symbol **subfunction**, the dspec is that list with the dspec of the parent function added as a third element. For example, if you have:

```
(defun my-parent (x)
  #'(lambda (y)
      (declare (lambda-name (subfunction sub-name)))
      (* x y)))
```

then the dspec of the subfunction that **my-parent** returns would be (**subfunction sub-name my-parent**).

**hcl:lambda-name** is useful for debugging purposes and does not affect the behavior of the program. There are two different situations when **hcl:lambda-name** is useful:

- In a defining form that has a similar effect to the effect of **defun**, (that is creating a "top-level" function at load-time). In this case, you should also use **def** to be able to locate the source. For example, look at the output of  
`(pprint (macroexpand-1 '(defun func-name ()))).`
- In a "run time" subfunction (that is a subfunction created by a code at run time by executing **(function (lambda ...))**). In this case, you should be using the **(subfunction sub-name)** form above, so the recorded name contains the dspec of the parent function, otherwise the debugger will not be able to find the source from the subfunction.

`hcl:lambda-name` will also modify the function name of `flet` and `labels`, but these already have a name, so this is not often useful.

Naming functions and subfunctions is useful because it makes it easier to understand the flow of control when you see them in a backtrace. For subfunctions, it makes it easier to trace and advise them (see `trace` and `defadvice`).

Description of :`explain` The remainder of this description documents the syntax and use of `:explain` declarations.

***declaration*** ::= (:`explain` *option\**)

***option*** ::= *optionkey* | (*optionkey optionvalue*)

***optionkey*** ::= :`none` | :`variables` | :`types` | :`floats` | :`non-floats` | :`all-calls` | :`all-calls-with-arg-types` | :`calls` | :`boxing` | :`print-original-form` | :`print-expanded-form` | :`print-length` | :`print-level`

The `:explain` declaration controls messages printed by the compiler while it is processing forms. The declaration can be used with `proclaim` or `declaim` as a top level form to give it global or file scope. It can also be used at the start of a `#'lambda` form or function body to give it the scope of that function. The declaration has unspecified effect when used in other contexts, for example in the body of a `let` form.

An `:explain` declaration consists of a set of options of the form (*optionkey optionvalue*) which associates *optionvalue* with *optionkey* or *optionkey* which associates `t` with *optionkey*. By default, all of the *optionkeys* have an associated value `nil`. All *optionkeys* not specified by a declaration remain unchanged (except for the special action of the `:none` *optionkey* described below).

The *optionkey* should be one of the following:

**`:none`** Set value associated with all *optionkeys* to `nil`. This turns off all explanations.

|                                  |                                                                                                                                                                                             |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:variables</b>                | If <i>optionvalue</i> is non-nil, list all the variables of each function, specifying whether they are floating point or not.                                                               |
| <b>:types</b>                    | If <i>optionvalue</i> is non-nil, print information about compiler transformations that depend on declared or deduced type information.                                                     |
| <b>:floats</b>                   | If <i>optionvalue</i> is non-nil, print information about calls to functions that may allocate floats.                                                                                      |
| <b>:non-floats</b>               | If <i>optionvalue</i> is non-nil, print information about calls to functions that may allocate non-float numbers, for example bignums.                                                      |
| <b>:all-calls</b>                | If <i>optionvalue</i> is non-nil, print information about calls to normal functions.                                                                                                        |
| <b>:all-calls-with-arg-types</b> | If <i>optionvalue</i> is non-nil, print the argument types for calls to normal functions. Must be combined with <b>:all-calls</b> .                                                         |
| <b>:calls</b>                    | A synonym for <b>:all-calls</b> .                                                                                                                                                           |
| <b>:boxing</b>                   | If <i>optionvalue</i> is non-nil, print information about calls to functions that may allocate numbers, for example floats or bignums.                                                      |
| <b>:print-original-form</b>      | If <i>optionvalue</i> is non-nil, modifies the <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations to include the original source code form that contains the call.      |
| <b>:print-expanded-form</b>      | If <i>optionvalue</i> is non-nil, modifies the <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations to include the macroexpanded source code form that contains the call. |

- :print-length** Use the *optionvalue* as the value of  
     \***print-length\*** for :all-calls, :floats  
     and :non-floats explanations.
- :print-level** Use the *optionvalue* as the value of  
     \***print-level\*** for :all-calls, :floats  
     and :non-floats explanations.

|         |                                                                                                                                                                                                                                                                                                                                                                               |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | <pre>(defun foo (arg)   (declare     (:explain :variables)     (optimize (float 0)))   (let* ((double-arg (coerce arg 'double-float))          (next (+ double-arg 1d0))          (other (* double-arg 1/2)))     (values next other)))   ;;- Variables with non-floating point types:   ;;- ARG OTHER   ;;- Variables with floating point types:   ;;- DOUBLE-ARG NEXT</pre> |

|                 | <i>Macro</i>                                                                                                                                                                  |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>defclass</b> |                                                                                                                                                                               |
| Summary         | Remains as defined in ANSI Common Lisp, but extra control over parsing of class options and slot options, optimization of slot access, and checking of initargs, is provided. |
| Package         | <code>common-lisp</code>                                                                                                                                                      |
| Description     | The macro <b>defclass</b> is as defined in the ANSI standard with the following extensions.                                                                                   |

For extra class options, you may need to define the way these are parsed at `defclass` macroexpansion time. See `process-a-class-option` for details.

For non-standard slot options, you may need to define the way these are parsed at `defclass` macroexpansion time. See `process-a-slot-option` for details.

By default, standard slot accessors are optimized such that they do not call `slot-value-using-class`. This optimization can be switched off using the `:optimize-slot-access nil` class option.

To add valid initialization arguments for the class, use the class option `:extra-initargs`. The argument passed via this option is evaluated, and should return a list of extra initialization arguments for the class. `make-instance` and other CLOS initializations (see `set-clos-initarg-checking`) will treat these as valid when checking their arguments.

Compatibility notes

1. When a class is redefined, its extra initargs are always reset.
2. In early versions of LispWorks 4.3, extra initargs were not reset when a class was redefined without specifying extra initargs.

Example

This session illustrates the effects of the `:optimize-slot-access` class option. When true, slot access is more efficient but note that `slot-value-using-class` is not called.

```

CL-USER 26 > (compile '(defclass foo ()
  ((a :type fixnum
    :initarg :a
    :reader foo-a))))
NIL

CL-USER 27 > (compile '(defclass bar ()
  ((a :type fixnum
    :initarg :a
    :reader bar-a))
  (:optimize-slot-access nil)))
NIL

CL-USER 28 > (setf *foo*
  (make-instance 'foo :a 42)
  *bar* (make-instance 'bar :a 99))
#<BAR 21D33D4C>

CL-USER 29 > (progn
  (time (dotimes (i 1000000)
    (foo-a *foo*)))
  (time (dotimes (i 1000000)
    (bar-a *bar*))))
Timing the evaluation of (DOTIMES (I 1000000) (FOO-A
*FOO*))

user time      =      0.328
system time   =      0.015
Elapsed time =  0:00:00
Allocation   = 2280 bytes standard / 11002882 bytes
conses
0 Page faults
Timing the evaluation of (DOTIMES (I 1000000) (BAR-A
*BAR*))

user time      =      0.406
system time   =      0.015
Elapsed time =  0:00:00
Allocation   = 4304 bytes standard / 11004521 bytes
conses
0 Page faults
NIL

CL-USER 30 > (trace
  (clos:slot-value-using-class
  :when
  (and (member (first *traced-arglist*)

```

```
(list (find-class 'foo)
      (find-class 'bar)))
      (eq (third *traced-arglist*) 'a))))
(CLOS:SLOT-VALUE-USING-CLASS)

CL-USER 31 > (foo-a *foo*)
42

CL-USER 32 > (bar-a *bar*)
0 CLOS:SLOT-VALUE-USING-CLASS > ...
  >> CLASS          : #<STANDARD-CLASS BAR 214897F4>
  >> CLOS::OBJECT    : #<BAR 2148820C>
  >> CLOS::SLOT-NAME : A
0 CLOS:SLOT-VALUE-USING-CLASS < ...
  << VALUE-0 : 99
99
```

This session illustrates the `:extra-initargs` class option:

```

CL-USER 46 > (defclass a () ())
              (:extra-initargs '(:a-initarg)))
#<STANDARD-CLASS A 21C2E4FC>

CL-USER 47 > (defclass b (a) ())
              (:extra-initargs '(:b-initarg)))
#<STANDARD-CLASS B 2068573C>

CL-USER 48 > (defclass c (a) ())
#<STANDARD-CLASS C 22829D44>

CL-USER 49 > (make-instance 'b :a-initarg "A" :b-
initarg "B")
#<B 2068BCE4>

CL-USER 50 > (make-instance 'c :a-initarg "A" :b-
initarg "B")

Error: MAKE-INSTANCE is called with unknown keyword :B-
INITARG among the arguments (C :A-INITARG "A" :B-
INITARG "B") which is not one of (:A-INITARG).
 1 (continue) Ignore the keyword :B-INITARG
 2 (abort) Return to level 0.
 3 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

| Description | <p>The macro <code>defpackage</code> is as defined in the ANSI standard, with the inclusion of the <code>:add-use-defaults</code> keyword. However, the standard explicitly declines to define what <code>defpackage</code> does if a package named <i>defined-package-name</i> already exists and is in a state that differs from that described by the <code>defpackage</code> form.</p> <p>Therefore an extension has been written that allows you to select between alternative behaviors. See <code>*handle-existing-defpackage*</code> for full details.</p> <p>One non-standard <i>option</i> is supported. <code>:add-use-defaults</code>, with a true argument, causes the package <i>defined-package-name</i> to inherit from the following packages (as well as any explicitly specified by the <code>:use</code> option):</p> <ul style="list-style-type: none"> <li>• <code>common-lisp</code></li> <li>• <code>lispworks</code></li> <li>• <code>harlequin-common-lisp</code></li> </ul> |                      |
| Example     | <pre>(defpackage "MY-PACKAGE" (:use "CAPI")             (:add-use-defaults t))  (package-use-list "MY-PACKAGE") =&gt; (#&lt;PACKAGE COMMON-LISP&gt; #&lt;PACKAGE LISPWORKS&gt; #&lt;PACKAGE HARLEQUIN-COMMON-LISP&gt; #&lt;PACKAGE CAPI&gt;)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary     | Remains as defined in ANSI Common Lisp. Additionally, you can control the depth at which slots inside arrays, structures and conses are described.                                                                                                                                                                                                          |                 |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                    |                 |
| Signature   | <code>describe <i>object</i> &amp;optional <i>stream</i> =&gt; &lt;no-values&gt;</code>                                                                                                                                                                                                                                                                     |                 |
| Arguments   | <p><i>object</i>            An object.</p> <p><i>stream</i>          An output stream designator.</p>                                                                                                                                                                                                                                                       |                 |
| Description | <p>The function <code>describe</code> displays information about the object object to the stream indicated by stream, as specified in ANSI Common Lisp.</p> <p>Arrays, structures and conses are described recursively up to the depth given in the value of the variable <code>*describe-level*</code>. Beyond that depth, objects are simply printed.</p> |                 |

|           |                                                                                                                                                                                                  | <i>Function</i> |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary   | Determines which files on the system have names matching a given pathname.                                                                                                                       |                 |
| Package   | <code>common-lisp</code>                                                                                                                                                                         |                 |
| Signature | <code>directory <i>pathname</i> &amp;key <i>test</i> <i>directories</i> <i>flat-file-namestring</i> <i>link-transparency</i> <i>non-existent-link-destinations</i> =&gt; <i>pathnames</i></code> |                 |
| Arguments | <i>pathname</i> A pathname, string, or file-stream.                                                                                                                                              |                 |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>test</i>                           | Filtering test (only pathnames matching the test are collected).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>directories</i>                    | A boolean controlling whether non-matching directories are included in the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>flat-file-namestring</i>           | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>link-transparency</i>              | If <code>nil</code> , then symbolic links are not followed. This means that returned names are not necessarily truenames, but has the useful feature that the <code>pathname-directory</code> of each pathname returned is the directory supplied as argument.<br><br>The default value of <i>link-transparency</i> is given by the special variable, <code>*directory-link-transparency*</code> , which has initial value <code>t</code> on non-Windows platforms. By setting this variable to <code>nil</code> , you can get the old behavior of <code>directory</code> . On Windows, where the file system does not normally support symbolic links, this variable is initially <code>nil</code> . |
| <i>non-existent-link-destinations</i> | If this is non-nil, then the pathname pointed to by a symbolic link appears in the output whether or not this file actually exists. If <code>:link-transparency</code> is non-nil and <code>:non-existent-link-destinations</code> is <code>nil</code> (this is the default on non-Windows platforms), then symbolic links to nonexistent files do not appear.<br><br>The default value is <code>nil</code> .                                                                                                                                                                                                                                                                                         |
| Values                                | <i>pathnames</i><br>A list of physical pathnames.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>directory</code> collects all the pathnames matching the given pathname.</p> <p><code>directory</code> returns truenames, conforming to the ANSI specification for Common Lisp. Some programs may depend on the old behavior, however (and <code>directory</code> is slower if it has to find the truename for every file in the directory), and so two keyword arguments are available so that the old behavior can still be used: <i>link-transparency</i> and <i>non-existent-link-destinations</i>.</p> <p>Because truenames are now returned, the entries <code>.</code> and <code>..</code> no longer show up in the output of <code>directory</code>. This means, for instance, that</p> <pre>(directory #P"/usr/users/")</pre> <p>does not include <code>#P"/usr"</code>, which is the truename of <code>#P"/usr/users/.."</code></p> <p>The specification is unclear as to the appropriate behavior of <code>directory</code> in the presence of links to non-existent files or directories. For example, if the directory contains <code>foo</code>, which is a symbolic link to <code>bar</code>, and there is no file named <code>bar</code>, should <code>bar</code> show up in the directory listing? A keyword argument has been added which lets you control this behavior.</p> <p><code>directory</code> returns a single pathname if called with a non-wild (fully-specified) <i>pathname</i>. LispWorks <i>truenames</i> are fully-specified, so this affects recursive calls to <code>directory</code>.</p> <p><code>directories</code>, if non-nil, causes paths of directories that are sub-directories of the directory of the argument <i>pathname</i> to be included in the result, even if they do not match <i>pathname</i> in the name, type or version components. The default value of <code>directories</code> is <code>nil</code>.</p> <p>When <code>flat-file-namestring</code> is non-nil, <code>directory</code> matches the <code>file-namestring</code> of <i>pathname</i> as a flat string, rather than a</p> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

pathname name and pathname type. The default value of *flat-file-namestring* is `nil`.

## Notes

1. The Search files tool in the LispWorks IDE uses this option when the **Match flat file-namestring** option is selected. See the *LispWorks IDE User Guide* for more information about the Search Files tool.
2. File names containing the character \* cannot be handled by LispWorks. This is because LispWorks uses \* as a wildcard, so there can be confusion if a file name containing \* is created, for example in the *pathnames* returned by `directory`.
3. The function `fast-directory-files` can be used for faster operations when operating on directories with large number of files.

## Compatibility notes

The `:check-for-subs` argument, implemented in LispWorks 4.0.1 and previous versions, has been removed. This argument controlled whether directories in the result have null name components. This option is no longer valid since ANSI Common Lisp specifies that `directory` returns true-names.

## Example

```
CL-USER 1 > (pprint (directory "."))
(#P"C:/Program Files/LispWorks/readme-6-1.txt"
 #P"C:/Program Files/LispWorks/lispworks-6-1-0-x86-
win32.exe"
 #P"C:/Program Files/LispWorks/license-6-1.txt"
 #P"C:/Program Files/LispWorks/lib/")
```

This session illustrates the effect of the *directories* argument:

```

CL-USER 5 > (pprint (directory "/tmp/t*"))

(#P"/tmp/test.lisp" #P"/tmp/test2/" #P"/tmp/test1/")

CL-USER 6 > (pprint (directory "/tmp/t*" :directories
t))

(#P"/tmp/patches/"
 #P"/tmp/test.lisp"
 #P"/tmp/test2/"
 #P"/tmp/opengl/"
 #P"/tmp/test1/"
 #P"/tmp/mnt/")

```

This example illustrates directory returning a single pathname in its result when given a full-specified pathname:

```

CL-USER 1 > (directory
               (make-pathname :host "H"
                             :device :unspecific
                             :directory (list :absolute
   "tmp")
                             :name :unspecific
                             :type :unspecific
                             :version :unspecific))
               (#P"H:/tmp/")

```

The next two examples illustrate the effect of *flat-file-namestring*. Suppose the directory *dir* contains files *interp.exe* and *file.lisp*.

This call matches *interp.exe*, where the name *interp* ends with *p*, but does not match *file.lisp*, where the name *file* ends with *e*:

```
(directory "dir/*p")
```

The next call matches *file.lisp*, where the namestring *file.lisp* ends with *p*, but does not match *interp.exe*, where the namestring *interp.exe* ends with *e*:

```
(directory "dir/*p" :flat-file-namestring t)
```

| Summary            | Prints the machine code of a compiled function.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Package            | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Signature          | <code>disassemble name-or-function =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments          | <code>name-or-function</code> Either a function object, a lambda expression or a symbol with a function definition.                                                                                                                                                                                                                                                                                                                                       |
| Description        | <p>This function prints the machine code of a compiled function, to <code>*standard-output*</code>.</p> <p>If the function denoted by <code>name-or-function</code> is not compiled then it is first compiled using the function <code>compile</code>. This happens if <code>name-or-function</code> is a lambda expression or a symbol naming an interpreted function.</p> <p>An error is signaled if <code>name-or-function</code> is not suitable.</p> |
| Examples           | <pre>(disassemble #'(lambda (x) (progn x))) (disassemble 'cons) (disassemble #'map)</pre>                                                                                                                                                                                                                                                                                                                                                                 |
| Notes              | The output from <code>disassemble</code> lacks useful information such as local and lexical variable names. The representation of integers or characters or Lisp objects in general is not easily readable without detailed knowledge of the internals of the Lisp system and the host machine instruction set.                                                                                                                                           |
| See also           | <code>compile</code><br><code>compile-file</code>                                                                                                                                                                                                                                                                                                                                                                                                         |

| Signature           | <code>documentation x doc-type =&gt; documentation</code><br><code>(setf documentation) new-value x doc-type =&gt; new-value</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description         | <p>The generic function <code>documentation</code> operates as specified in the ANSI Common Lisp standard. Additional methods with signatures:</p> <pre>documentation (dspec t) (doc-type (eql 'dspec:dspec)) (setf documentation) new-value (dspec t) (doc-type (eql 'dspec:dspec))</pre> <p>are provided.</p> <p>This method allows finding or setting the documentation string when you know the <code>dspec</code>. See Chapter 7, “Dspecs: Tools for Handling Definitions” for information about <code>dspecs</code>.</p> <p><code>dspec</code> must be a <code>dspec</code>, but it can be non-canonical. This method canonicalizes <code>dspec</code> and then calls <code>documentation</code> with the name as the first argument and the appropriate <code>dspec</code> class name as the second, thereby calling a standard <code>documentation</code> method.</p> <p>If you define your own type of definitions (<code>def-saved-value</code> for example) with <code>define-dspec-class</code> you can add methods on <code>documentation</code> for your <code>dspec</code> class:</p> <pre>(documentation (dspec t) (doc-type (eql 'def-saved-value)))</pre> <p>This allows commands in the LispWorks IDE such as <b>Expression &gt; Documentation</b> to display the documentation.</p> |
| <b>double-float</b> | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Summary             | A subtype of <code>float</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Description         | <code>double-float</code> is disjoint from <code>short-float</code> and <code>single-float</code> in all LispWorks implementations in version 5.0 and later.                                                                                                                                     |
| Compatibility notes | In LispWorks 4.4 and previous on Windows and Linux platforms, all floats are of type <code>double-float</code> . However, there are distinct specialized array types ( <code>(array single-float)</code> , with single precision, and <code>(array double-float)</code> , with double precision. |

| <b>*features*</b> |                                                                                                                                             | <i>Variable</i>                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Summary           | The features list.                                                                                                                          |                                                   |
| Package           | <code>common-lisp</code>                                                                                                                    |                                                   |
| Initial value     | A list containing <code>:lispworks</code> . The actual value varies depending on the platform.                                              |                                                   |
| Description       | The following features can be used to distinguish between platforms, or characteristics of the platform or of the LispWorks implementation. |                                                   |
|                   | <code>:solaris2</code>                                                                                                                      | Solaris2                                          |
|                   | <code>:aix</code>                                                                                                                           | AIX PowerPC                                       |
|                   | <code>:svr4</code>                                                                                                                          | System 5 Release 4 machine (for example Solaris2) |

|                                    |                                                                                                                                                                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:linux</code>                | Linux                                                                                                                                                                                                                                              |
| <code>:darwin</code>               | The variant of FreeBSD underlying Mac OS X.                                                                                                                                                                                                        |
| <code>:unix</code>                 | Unix, including all of the above.                                                                                                                                                                                                                  |
| <code>:mswindows</code>            | Microsoft Windows, including 32-bit and 64-bit.                                                                                                                                                                                                    |
| <code>:lispworks-64bit</code>      | 64-bit LispWorks.                                                                                                                                                                                                                                  |
| <code>:lispworks-32bit</code>      | 32-bit LispWorks.                                                                                                                                                                                                                                  |
| <code>:x86</code>                  | All images that run on the x86 architecture have this feature. This includes Intel Macintosh, FreeBSD, x86/x86_x64 Linux (32-bit), x86/x64 Solaris (32-bit) and Windows (32-bit).<br><br><b>Note:</b> 64-bit LispWorks does not have this feature. |
| <code>:amd64, :x86-64, :x64</code> | Images that run on the amd64/x86_64/x64 architecture have each of these features. This includes x86_x64 Linux (64-bit), FreeBSD (64-bit), x86/x64 Solaris (64-bit) and Windows (64-bit).                                                           |
| <code>:arm</code>                  | Images that run on 32-bit ARM architecture.                                                                                                                                                                                                        |
| <code>:arm64</code>                | Images that run on 64-bit ARM architecture.                                                                                                                                                                                                        |
| <code>:sparc</code>                | Images that run on SPARC architecture.                                                                                                                                                                                                             |
| <code>:powerpc</code>              | Images that run on PowerPC architecture.                                                                                                                                                                                                           |
| <code>:android-delivery</code>     | Images generating Android runtimes.                                                                                                                                                                                                                |
| <code>:ios-delivery</code>         | Images generating iOS runtimes.                                                                                                                                                                                                                    |

**:little-endian** The compiler targets a little-endian machine, for instance x86.

The following features are present in LispWorks with the meanings defined for ANSI CL:

```
:ansi-cl  
:common-lisp  
:ieee-floating-point
```

### Conditionalization for the LispWorks implementations

Code can distinguish the seventeen current LispWorks implementations like this:

```

#+(and :mswindows :x86)
" LispWorks (32-bit) for Windows"
#+(and :mswindows :x86-64)
" LispWorks (64-bit) for Windows"
#+(and :linux :x86)
" LispWorks (32-bit) for x86/x86_64 Linux"
#+(and :linux :x86-64)
" LispWorks (64-bit) for x86_64 Linux"
#+(and :linux :arm
      (not :android-delivery)
      (not :ios-delivery))
" LispWorks (32-bit) for ARM Linux"
#+(and :linux :arm64
      (not :android-delivery)
      (not :ios-delivery))
" LispWorks (64-bit) for ARM Linux"
#+(and :freebsd :x86)
" LispWorks (32-bit) for FreeBSD"
#+(and :freebsd :x86-64)
" LispWorks (64-bit) for FreeBSD"
#+(and :aix :lispworks-32bit)
" LispWorks (32-bit) for AIX"
#+(and :aix :lispworks-64bit)
" LispWorks (64-bit) for AIX"
#+(and :darwin :x86 (not :ios-delivery))
" LispWorks (32-bit) for Macintosh"
#+(and :darwin :x86-64)
" LispWorks (64-bit) for Macintosh"
#+(and :solaris2 :x86)
" LispWorks (32-bit) for x86/x64 Solaris"
#+(and :solaris2 :x86-64)
" LispWorks (64-bit) for x86/x64 Solaris"
#+(and :sparc :lispworks-32bit)
" LispWorks (32-bit) for SPARC Solaris"
#+(and :sparc :lispworks-64bit)
" LispWorks (64-bit) for SPARC Solaris"
#+:android-delivery
" LispWorks (32-bit) for Android Runtime"
#+(and :ios-delivery :x86)
" LispWorks (32-bit) for iOS Runtime simulator"
#+(and :ios-delivery :x86-64)
" LispWorks (64-bit) for iOS Runtime simulator"
#+(and :ios-delivery :arm)
" LispWorks (32-bit) for iOS Runtime"
#+(and :ios-delivery :arm)
" LispWorks (64-bit) for iOS Runtime"

```

## Conditionalization for LispWorks versions

The following features can be used to distinguish between versions of LispWorks:

- `:lispworks4` All major version 4 releases.
- `:lispworks4.4` Release 4.4.x
- `:lispworks5` All major version 5 releases.
- `:lispworks5.0` Release 5.0.x
- `:lispworks5.1` Release 5.1.x
- `:lispworks6` All major version 6 releases.
- `:lispworks6.0` Release 6.0.x
- `:lispworks6.1` Release 6.1.x
- `:lispworks7` All major version 7 releases.
- `:lispworks7.0` Release 7.0.x
- `:lispworks7.1` Release 7.1.x

Code using new LispWorks functionality should be conditionalized only using features representing earlier versions, so as to future-proof your code:

```
(defvar *feature-added-in-LispWorks-7.1*
  #+(or lispworks4 lispworks5 lispworks6 lispworks7.0)
nil
  #-(or lispworks4 lispworks5 lispworks6 lispworks7.0)
t)
```

This is because a feature added in LispWorks 7.1 will generally also be in LispWorks 7.2, LispWorks 8.0 and all later versions.

Similarly:

```
(defvar *feature-added-in-LispWorks-7.0*
  #+(or lispworks4 lispworks5 lispworks6) nil
  #-(or lispworks4 lispworks5 lispworks6) t)
```

or:

```
(defvar *feature-added-in-LispWorks-6.1*
  #+(or lispworks4 lispworks5 lispworks6.0) nil
  #-(or lispworks4 lispworks5 lispworks6.0) t)
```

We have seen several problematic examples like this:

```
(defvar *feature-added-in-LispWorks-6.0*
  #+lispworks6 t
  #-lispworks6 nil)
```

which breaks in LispWorks 7.0, because that release does not contain the `:lispworks6` feature.

In general you should use the `:lispworksx` and `:lisp-worksx.y` features "in reverse". That is, make your code work for the latest version of LispWorks and then add conditionalization for any previous versions that you want to support, if needed.

## Conditionalization for the LispWorks architectures

Every LispWorks 5, LispWorks 6 and LispWorks 7 image has exactly one of the features `:lispworks-32bit` and `:lisp-works-64bit`.

The two LispWorks architectures, 32-bit and 64-bit, can be distinguished by the features `:lispworks-32bit` or `:lisp-works-64bit`.

### Notes

1. For a LispWorks image with the CAPI loaded, `:capi` will appear on `*features*`.
2. LispWorks for Macintosh supports the native Mac OS X Cocoa-based GUI and the X11/GTK+ GUI. If you need to test for which of these libraries is loaded, check for the features `:cocoa` and `:gtk`. The X11/Motif GUI is also available by evaluating (`(require "capi-motif")`) in the GTK+ image.

3. Sometimes it is necessary to write code that examines `*features*` at load-time or run-time. For example this is true when you put platform-dependent code in fasl files that are shared between multiple platforms.

## **input-stream-p** *Generic Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | A generic function that determines if an object is an input stream.                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                        |
| Signature   | <code>input-stream-p stream =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |                        |
| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A stream.              |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A generalized boolean. |
| Description | The predicate <code>input-stream-p</code> is implemented as a generic function. The default method returns <code>t</code> if <code>stream</code> is an input stream. If the user wants to implement a stream with no inherent directionality (and thus does not include <code>fundamental-input-stream</code> or <code>fundamental-output-stream</code> ) but for which the directionality depends on the instance, then a method should be provided for <code>input-stream-p</code> . |                        |
| Examples    | There is an example in “Stream directionality” on page 400.                                                                                                                                                                                                                                                                                                                                                                                                                            |                        |

## **interactive-stream-p** *Function*

|         |                                                                           |
|---------|---------------------------------------------------------------------------|
| Summary | A generic function that determines if an object is an interactive stream. |
|---------|---------------------------------------------------------------------------|

|             |                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>c1</code>                                                                                                                                                                           |
| Signature   | <code>interactive-stream-p stream =&gt; result</code>                                                                                                                                     |
| Arguments   | <code>stream</code> A stream.                                                                                                                                                             |
| Values      | <code>result</code> A generalized boolean.                                                                                                                                                |
| Description | The predicate <code>interactive-stream-p</code> is implemented as a generic function. The <code>fundamental-stream</code> class provides a default method that returns <code>nil</code> . |

| <b>load-logical-pathname-translations</b> |                                                                                                                                                                | <i>Function</i> |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                                   | Searches for and loads the definition of a logical host, if not already defined.                                                                               |                 |
| Package                                   | <code>c1</code>                                                                                                                                                |                 |
| Signature                                 | <code>load-logical-pathname-translations host =&gt; just-loaded</code>                                                                                         |                 |
| Arguments                                 | <code>host</code> A logical host, expressed as a string.                                                                                                       |                 |
| Values                                    | <code>just-loaded</code> A generalized boolean                                                                                                                 |                 |
| Description                               | This function loads the translations for <code>host</code> by loading the file <code>host.lisp</code> from the LispWorks directory <code>translations</code> . |                 |
| Example                                   | <code>(load-logical-pathname-translations "EDITOR-SRC")</code>                                                                                                 |                 |

|                   |                                                                                                                |             |
|-------------------|----------------------------------------------------------------------------------------------------------------|-------------|
| <b>long-float</b> |                                                                                                                | <i>Type</i> |
| Summary           | A subtype of <code>float</code> .                                                                              |             |
| Package           | <code>common-lisp</code>                                                                                       |             |
| Signature         | <code>long-float</code>                                                                                        |             |
| Description       | <code>long-float</code> is the same type as <code>double-float</code> in LispWorks, on all platforms.          |             |
| See also          | <code>double-float</code><br><code>parse-float</code><br><code>short-float</code><br><code>single-float</code> |             |

|                       |                                                                                                                                                                                                                   |                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>long-site-name</b> |                                                                                                                                                                                                                   | <i>Function</i> |
| Summary               | Identifies the physical location of the computer.                                                                                                                                                                 |                 |
| Package               | <code>common-lisp</code>                                                                                                                                                                                          |                 |
| Signature             | <code>long-site-name =&gt; description</code><br><code>(setf long-site-name) description =&gt; description</code>                                                                                                 |                 |
| Arguments             | <code>description</code> A string or <code>nil</code> .                                                                                                                                                           |                 |
| Description           | The function <code>long-site-name</code> returns a string identifying the physical location of the computer. This should be set using <code>(setf long-site-name)</code> when you configure your LispWorks image. |                 |
| See also              | <code>short-site-name</code>                                                                                                                                                                                      |                 |

|             | <i>query-expression</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A SQL query-statement |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | An object.            |
| Description | <p>The Common Lisp <code>loop</code> macro has been extended with a clause for iterating over query results. This extension is available only when the SQL interface has been loaded. See Chapter 47, “The SQL Package”. For a full description of the rest of the Common Lisp <code>loop</code> facility, see the Common Lisp Hyperspec.</p> <p>Each iteration of the loop assigns the next record of the table to the variable <code>var</code>. The record is represented in Lisp as a list. Destructuring can be used in <code>var</code> to bind variables to specific attributes of the records resulting from <i>query-expression</i>. In conjunction with the panoply of existing clauses available from the <code>loop</code> macro, the new iteration clause provides an integrated report generation facility.</p> |                       |
| Example     | <p>This extended <code>loop</code> example, on each record returned as a result of the query, binds <code>name</code>, finds the salary (if any) from an associated hash-table, and for salaries greater than 20000: increments a count, accumulates the salary, and prints the details. Finally, the average salary is printed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                       |

```
(loop
  for (name) being each record in
  [select [ename] :from [emp]]
  as salary = (gethash name *salary-table*)
  initially (format t "~&~20A~10D" 'name 'salary)
  when (and salary (> salary 20000))
    count salary into salaries
    and sum salary into total
    and do (format t "~&~20A~10D" name salary)
  else
    do (format t "~&~20A~10A" name "N/A")
  finally
    (format t "~2&Av Salary: ~10D" (/ total salaries)))
```

Description The standard definition of `make-array` is extended to accept the keyword arguments `:weak`, `:allocation` and `:single-thread`.

If `weak` is non-nil, then `displaced-to` must be `nil` and if `element-type` is supplied it must have `upgraded-array-element-type t`, otherwise an error is signaled. That is, you cannot make a weak array which is displaced or has `array-element-type` other than `t`. When `weak` is non-nil, it makes `new-array` weak.

If `weak` is `nil`, then `make-array` behaves in the standard way, and `new-array` is not weak. The value `weak` defaults to `nil`. In 64-bit LispWorks, `allocation` cannot be used with `weak` and the length of a weak array must be less than 4194304 ( $2^{22}$ ) elements.

See `set-array-weak` for a description of weak arrays.

The possible values for `allocation` have the following meanings:

- `:new` Allocate the array normally.
- `nil` Same meaning as `:new`. This is the default value.
- `:static` Allocate the array in a static segment.
- `:long-lived` Allocate the array assuming it is going to be long-lived.
- `:old` Same meaning as `:long-lived`

Arrays (including strings) that are passed by address to foreign functions must be static, and so must should be created with `:allocation :static`.

Allocation with `:old` or `:long-lived` is useful when you know that the array will be long-lived, because your program will avoid the overhead of promoting it to the older generations.

If *single-thread* is true then the system knows that *new-array* will always be accessed in a single thread context. That makes some operations faster, in particular `vector-pop` and `vector-push`. The default value of *single-thread* is `nil`.

|                     |                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility notes | <i>allocation</i> can also be a fixnum <i>n</i> but this is now deprecated. The intent was to allocate the array in generation <i>n</i> , however the allocation is not actually guaranteed to be in the specified generation (although it will be in almost every call). |

| <i>free-function</i> | A designator for a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description          | <p>The standard definition of <code>make-hash-table</code> is extended such that <i>test</i> can be any suitable user-defined function, except that it must not call <code>process-wait</code> or similar <code>mp</code> package functions which suspend the current process. If <i>test</i> is not one of the standard test functions (<code>eq</code>, <code>eq1</code>, <code>equal</code> and <code>equalp</code>), and if <i>hash-function</i> is not supplied, then the hash value is the same as would be used if <i>test</i> were <code>equalp</code>.</p> <p><i>hash-function</i> may be supplied only if <i>test</i> is not one of the standard test functions. It takes a hash key as its argument and returns a hash value to use for hashing.</p> <p>If <i>weak-kind</i> is non-nil, it makes <i>hash-table</i> weak. Its semantics are the same as the second argument of <code>set-hash-table-weak</code>, that is:</p> <pre>(make-hash-table :weak-kind <i>weak-kind</i> &lt;other-args&gt;)</pre> <p>is equivalent to</p> <pre>(let ((ht (make-hash-table &lt;other-args&gt;)))   (set-hash-table-weak ht <i>weak-kind</i>)   ht)</pre> <p>The default value of <i>weak-kind</i> is <code>nil</code>.</p> <p><i>single-thread</i>, if true, tells <code>make-hash-table</code> that the table is going to be used only in single thread contexts, and therefore does not need to be thread-safe. Single thread context means that only one thread can access the table at any point in time. That may be because the table is used only in one thread, but it can also be the case if the table is only ever accessed in the scope of a <code>lock</code>. Making a table with <i>single-thread</i> makes access to this table faster, but not thread-safe. It does not have other effects. The default value of <i>single-thread</i> is <code>nil</code>.</p> <p><i>free-function</i> adds a "free action" for a weak hash table. This has an effect only if <code>make-hash-table</code> is called with <i>weak-kind</i> non-nil. The <i>free-function</i> is called after an entry is auto-</p> |

matically removed by the garbage collector (GC). If *weak-kind* is `nil`, *free-function* is ignored.

*free-function*, if supplied, must take two arguments: *key* and *value*. When an entry is removed from a weak table *hash-table* because the relevant object is not pointed by any other object, the *key* and the *value* are remembered. Some time later (normally short, but not well-defined) the *free-function* is called with *key* and *value* as its arguments.

*free-function* needs to be fast, to avoid delays in unexpected places. Otherwise there are no restrictions on what *free-function* does. In particular, it can keep the *key* or *value* alive by storing them somewhere.

When objects are removed from the table by explicit calls (`remhash`, `clrhash`, (`setf gethash`)), *free-function* is not called.

**Notes** Objects are removed from the table when the GC has identified them as free. For long-lived objects, which normally get promoted to higher generations, that may be quite a long time after the last pointer to them has gone.

*free-function* can also be specified in a call to `set-hash-table-weak`.

## make-instance

## Generic Function

**Summary** Creates and returns a new instance of a class.

**Package** `common-lisp`

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                |

| Values              | <code>instance</code>                                                                                                                                                                                                                                                                                                                                                                                                                                       | A fresh instance of class <code>class</code> . |
| Description         | <p><code>make-instance</code> behaves as specified in ANSI Common Lisp. In particular it checks the initialization arguments as calculated by <code>compute-class-potential-initargs</code>. This check can be suppressed by passing <code>:allow-other-keys t</code>. In addition, LispWorks provides global control over the initarg checking via <code>set-clos-initarg-checking</code> and per-class control via <code>class-extra-initargs</code>.</p> |                                                |
| Notes               | In a delivered image, <code>make-instance</code> does not check the initialization arguments.                                                                                                                                                                                                                                                                                                                                                               |                                                |
| Compatibility notes | In LispWorks 4.2 and previous versions, <code>make-instance</code> does not check the initargs. If your code contains invalid initargs, you could use one of the techniques mentioned above to resolve it.                                                                                                                                                                                                                                                  |                                                |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>make-string</code> behaves as specified in the ANSI Common Lisp Standard with one exception: the default value of <code>element-type</code> is the value of <code>*default-character-element-type*</code> or the type of <code>initial-element</code> if that is a supertype of <code>*default-character-element-type*</code> .<br><br>Therefore for strict compliance you must call <code>set-default-character-element-type</code> to set the default string element type to <code>character</code> . |
| See also    | <code>*default-character-element-type*</code><br><code>set-default-character-element-type</code><br><code>simple-string</code>                                                                                                                                                                                                                                                                                                                                                                                             |

## **make-string-output-stream** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                              |  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Creates a character output stream.                                                                                                                                                                                                                                                                                                                                                                           |  |

## map *Function*

Summary      Redefines the standard `map` function allowing it to take any type specifier.

Package      `common-lisp`

Signature      `map result-type function &rest sequences => result`

Arguments      `result-type`      A sequence type specifier or `nil`.  
`function`      A function designator.  
`sequence`      A sequence.

Values      `result`      A sequence.

Description      The function `map` has been extended to take any Common Lisp type. The `result` will be of type `result-type` unless this is not possible, in which case a `type-error` is signaled.

`merge`

## merge *Function*

Summary      Redefines the standard `merge` function allowing it to take any type specifier.

Package      `common-lisp`

| <i>element-type</i>      | By default, the value of <code>*default-character-element-type*</code> (the ANSI standard default is <code>character</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>external-format</i>   | An external file format designator. By default, this is <code>:default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>if-exists</i>         | What to do if the file stream already exists. The possible values for this are as in the ANSI standard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>if-does-not-exist</i> | What to do if the file stream does not already exist. The possible values for this are as in the ANSI standard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values                   | <i>stream</i> A file stream, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description              | <p>If <i>external-format</i> has a name which is not <code>:default</code> and the parameters include <code>:eol-style</code>, it is used as is.</p> <p>Otherwise, the system decides which external format to use via <code>guess-external-format</code>. By default, this finds a match based on the filename; or (if that fails), looks in the EMACS-style (-*) attribute line for an option called <code>encoding</code> or <code>external-format</code> or <code>coding</code>; or (if that fails), chooses from among likely encodings by analyzing the bytes near the start of the file. By default, it then also analyzes the start of the file for byte patterns indicating the end-of-line style, and uses a default end-of-line style if no such pattern is found. This behavior is configurable.</p> <p>After the external-format has been determined, it is verified using <code>valid-external-format-p</code>; and an error is signaled if this check fails.</p> <p>If <code>open</code> gets <code>:default</code> as its <i>element-type</i> arg, it chooses the type on the basis of the external format. If <code>open</code> gets an <i>element-type</i> other than <code>:default</code> and the direction is <code>:input</code> or <code>:io</code>, the argument must be a supertype of the type of characters produced by the external format; if the direction is <code>:out-</code></p> |

`put` or `:io`, it must be a subtype of the type of characters accepted by the external format; if it does not satisfy these requirements, an error is signaled.

Standard stream input and output functions for character and binary data generally work in the obvious way on a `file-stream` with `element-type base-char`, `(unsigned-byte 8)` or `(signed-byte 8)`. For example, `read-sequence` can be called with a string buffer and a binary `file-stream`: the character data is constructed from the input as if by `code-char`. Similarly `write-sequence` can be called with a string buffer and a binary `file-stream`: the output is converted from the character data as if by `char-code`. Also, 8-bit binary data can be read from and written to a `base-char file-stream`.

All standard stream I/O functions except for `write-byte` and `read-byte` have this flexibility.

| Arguments   | <code>stream</code> A stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <code>result</code> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description | The predicate <code>output-stream-p</code> is implemented as a generic function. The default method returns <code>t</code> if <code>stream</code> is an output stream. If the user wants to implement a stream with no inherent directionality (and thus does not include <code>fundamental-input-stream</code> or <code>fundamental-output-stream</code> ) but for which the directionality depends on the instance, then a method should be provided for <code>output-stream-p</code> . |
| Examples    | There is an example in “Stream directionality” on page 400.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| See also    | <code>fundamental-output-stream</code><br><code>input-stream-p</code>                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>proclaim</b> | <i>Function</i>                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary         | Established a specified declaration in the global environment.                                                                                                                                                                                                                                                                             |
| Package         | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                   |
| Signature       | <code>proclaim <b>declaration-list</b> =&gt; nil</code>                                                                                                                                                                                                                                                                                    |
| Arguments       | <code>declaration-list</code> A list of declaration forms to be put into immediate and pervasive effect.                                                                                                                                                                                                                                   |
| Values          | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                 |
| Description     | Unlike <code>declare</code> , <code>proclaim</code> is a function that parses the declarations in the list (usually a quoted list), and puts their semantics and advice into global effect. This can be useful when compiling a file for speedy execution, since a proclamation such as:                                                   |
|                 | <pre>(proclaim '(optimize (speed 3) (space 0) (debug 0)))</pre> means the rest of the file is compiled with these optimization levels in effect. Other ways of doing this are:                                                                                                                                                             |
|                 | <ul style="list-style-type: none"> <li>• use the <code>:optimize</code> option in <code>defsystem</code> to establish default optimization qualities for every member of the system, when compiled via <code>compile-system</code>.</li> <li>• add appropriate <code>declare</code> declarations in every function in the file.</li> </ul> |
|                 | As <code>proclaim</code> involves parsing a list of lists of symbols and is intended to be used a few times per file at most, its implementation is not optimized for speed - it makes little sense to use it other than at top level.                                                                                                     |
|                 | <b>Note:</b> For a top-level call to <code>proclaim</code> or <code>declaim</code> , optimize declarations are omitted from the compiled binary file. This deviates from the ANSI Common Lisp Standard but is useful because you are unlikely to want to change settings outside                                                           |

of that file. To make the global settings, you can call a function which calls `proclaim` (so it is not a top-level call).

See “Compiler control” on page 104 for a more extended description of the compiler optimize qualities.

**Examples**

```
(proclaim '(special *fred*))  
(proclaim '(type single-float x y z))  
(proclaim '(optimize (safety 0) (speed 3)))
```

**Notes**

As `proclaim` involves parsing a list of lists of symbols and is intended to be used a few times per file, its implementation is not optimized for speed — it makes little sense to use it other than at top level.

Remember to quote the argument list if it is a constant list. `(proclaim (special x))` attempts to call function `special`.

Exercise caution if you declare or proclaim variables to be special without regard to the naming convention that surrounds their names with asterisks.

## restart-case

*Macro*

**Summary**

Evaluates a restartable form in a special dynamic environment.

**Package**

`common-lisp`

**Signature**

`restart-case restartable-form {clause} => result*`

```
clause ::= (case-name lambda-list [[:interactive interactive-expression | :report report-expression | :test test-expression] ] declaration* form*)
```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <b>restart-case</b> behaves as specified in the ANSI Common Lisp standard.<br><br>In addition to that specification, <i>report-expression</i> may be a form whose <b>car</b> is <b>list</b> . Such a form is evaluated when the restart is set up and is expected to return a list of a format string and format arguments. When the restart is asked to report, this is done by calling <b>format</b> on the stream, the format string and the format arguments. This is more efficient than specifying an equivalent function, because no function object is created. |

| Summary     | Print information about the state of internal memory and its management.                                                                                                                                                                                                                                               |
| Package     | <b>common-lisp</b>                                                                                                                                                                                                                                                                                                     |
| Signature   | <b>room &amp;optional x</b>                                                                                                                                                                                                                                                                                            |
| Arguments   | <b>x</b><br>One of <b>nil</b> , <b>t</b> , or the keyword <b>:default</b> . Additionally in 64-bit LispWorks only, <b>x</b> can be the keyword <b>:full</b> .                                                                                                                                                          |
| Values      | <b>room</b> returns no values.                                                                                                                                                                                                                                                                                         |
| Description | This function provides statistics on the current state of the memory, including the amount of space currently allocated, and the amount available for allocation.<br><br>As outlined in the Common Lisp Hyperspec, the <b>room</b> function takes an optional argument which controls the level of detail it produces. |

The output of `room` differs between 32-bit and 64-bit LispWorks, and is described separately below.

### **Output of `room` in 32-bit LispWorks**

Given an argument of `nil`, a summary of the total allocation in the entire heap (in kilobytes) is produced. The “allocated” figure only represents the amount of space allocated in heap segments that are writable, as opposed to read-only segments that hold some of the system code such as the garbage collector (GC) itself. The free space figure covers all the free space in all segments. To obtain these values programmatically, call `room-values`.

When called without an argument, `room` additionally prints information on the distribution of space between the generations of the heap.

When called with argument `t`, a breakdown of allocation in the individual segments of each generation is produced. Each segment is identified by its start address in memory. For each segment there is a free space threshold (the “minimum free space”)—when the available space in the segment falls below this value, the GC takes action to attempt to free more space in this segment.

Two statistics about promotion are also reported on a per-segment basis: the number of sweeps that an object must survive in this generation before becoming eligible for promotion, and the total volume of objects that have survived for that long and are consequently awaiting promotion to the next generation. These statistics are not relevant for static segments, which are indicated as “static”.

`room` prints numbers in decimal format, except for the segment start addresses which it prints in hexadecimal format.

## Output of room in 64-bit LispWorks

The last line of the output of `room` is always a line containing the total allocated amount (memory occupied by live objects) and the total size (memory that LispWorks has allocated from the OS) (the "total line"). Both numbers are given in decimal followed parenthetically by the same number in hexadecimal. Above the total line is information for each generation.

`(room nil)` does not print any information about generations.

`(room)` prints the amount allocated for each generation in decimal.

`(room :full)` prints for each generation the amount allocated, both in decimal and in hexadecimal, and then the allocated amount of each allocation type in which there is any allocation in this generation.

`(room t)` prints for each generation the same as `(room :full)`, followed by information about the segments in this generation. For each segment it prints the allocation type and the start and end address for allocation in this segment.

Note that information for segments does not correspond to the allocated size, because not all the area in the segment is currently allocated.

See "Memory Management in 64-bit LispWorks" on page 146 for a description of allocation types and segments.

## Output of room in the Mobile GC

The last line of the output of `room` is always a line containing the total allocated amount (memory occupied by live objects) and the total size (memory that LispWorks has allocated from the OS) (the "total line"). Both numbers are given in decimal followed parenthetically by the same number in hexadecimal. Above the total line is information for each generation.

(`room`) and (`room :default`) prints the allocated and free sizes according to these types:

|        |                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------|
| Cons   | <code>cons</code> object only.                                                                                 |
| Other  | All other objects, except static objects and large objects (> 1 MB).                                           |
| Static | Static objects.                                                                                                |
| Large  | Large objects (> 1 MB). Note: this threshold may change in the future, but it is fixed in the current version. |

The Cons and Other segments are divided according to their generation and there may also some permanent segments (as a result of a call to `make-current-allocation-permanent`, `make-object-permanent` or `make-permanent-simple-vector`).

In addition, LispWorks also holds some reserved segments that are used during GC, and `room` prints the size of these too.

(`room t`) also prints the segments for each type. For each segment, it prints the start and end addresses (in hex), the allocated area, and whether there is a free "hole" in the middle of it. For the Large and Static segments, it also prints the generation number of each segment. Permanent Static and Large segments have generation number 3.

See “Mobile GC technical details” on page 154 for more technical details.

|       |                                                                                                                                                                                                                                                                                                                                                |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | The segments information is useful for debugging problems with memory management, but for analysis of application allocation ( <code>room :full</code> ) gives enough information. Especially for very large images, there are many segments, so the output of ( <code>room t</code> ) is very large and not so useful (except for debugging). |

|                     | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary             | A subtype of <code>float</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Package             | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature           | <code>single-float</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description         | <p>A <code>single-float</code> is an immediate object in 64-bit LispWorks.</p> <p>A <code>single-float</code> is a boxed object in 32-bit LispWorks.</p> <p><code>single-float</code> is disjoint from <code>double-float</code> in all LispWorks implementations, version 5.0 and later.</p> <p><code>single-float</code> is disjoint from <code>short-float</code> in all 32-bit LispWorks implementations in version 5.0 and later. In 64-bit LispWorks <code>single-float</code> is the same type as <code>short-float</code>.</p> |
| Compatibility notes | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>single-float</code> is the same type as <code>double-float</code> . However, there are distinct specialized array types <code>(array single-float)</code> , with single precision, and <code>(array double-float)</code> , with double precision.                                                                                                                                                                                                                  |

| Description         | The function <code>software-version</code> returns a string giving the version of the Operating System, or <code>nil</code> if this cannot be determined.                                                                                                                                                                                                                                   |
|                     | On Microsoft Windows systems, <i>description</i> begins with the specific Operating System. For supported systems this is "Windows Vista", "Windows Server 2008", "Windows 7", "Windows Server 2008 R2", "Windows 8", "Windows 10", "Windows Server 2012" or "Some Windows NT derivative". This is followed by the version numbers (Major.Minor), build number and optionally service pack. |
| Compatibility notes | On older unsupported operating systems, the <i>description</i> commences with "Windows 95", "Windows 98", "Windows Millennium", "Windows NT", "Windows 2000" or "Windows XP".                                                                                                                                                                                                               |

Prior to LispWorks 7.1, the description begins with "Windows 8" when running on Windows 10.

Example

```
(software-version)
=>
"Windows 8: 6.2 (build 9200) "

(software-version)
=>
"Windows 7: 6.1 (build 7600) "

(software-version)
=>
"Windows Vista: 6.0 (build 6000)"
```

**\*standard-output\***

**\*trace-output\***

**\*error-output\***

**\*query-io\***

**\*debug-io\***

*Variables*

Summary

These are bound globally to synonyms to the **\*background-\*** streams:

Package

`common-lisp`

Initial value

Synonyms to the **\*background-\*** streams.

Description

The variables **\*standard-input\***, **\*standard-output\***, **\*trace-output\***, **\*error-output\***, **\*query-io\*** and **\*debug-io\*** are bound globally to synonyms to the various default streams as follows:

- **\*standard-input\*** - synonym to **\*background-input\***

- `*standard-output*`, `*trace-output*` and `*error-output*` - synonym to `*background-output*`
- `*query-io*` and `*debug-io*` - synonym to `*background-query-io*`

See `*background-input*` for details.

## **step** *Macro*

Summary      Steps through the evaluation of a form.

Package      `common-lisp`

Signature      `step form => result`

Arguments      `form`                  A form to be stepped and evaluated.

Values      `result`                  The values returned by `form`.

Description      `step` evaluates a form and allows you to single-step through it. You can include a call to `step` inside a tricky definition to invoke the stepper every time the definition is used. `step` can also optionally step through macros.

The commands shown below are available. When certain stepper variables (as described below) are set, some of these commands are not relevant and are therefore not available. Use `:help` to get a list of the commands.

`:s n`                  Step this form and all of its subforms (optional positive integer argument).

`:st`                  Step this form without stepping its sub-forms.

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <code>:su</code>   | Step up out of this form without stepping its subforms.             |
| <code>:sr</code>   | Return a value to use for this form.                                |
| <code>:sq</code>   | Quit from the current stepper level.                                |
| <code>:redo</code> | Redo one of the previous commands.                                  |
| <code>:get</code>  | Get an item from the history list and put it in a variable.         |
| <code>:help</code> | List available commands.                                            |
| <code>:use</code>  | Replace one form with another form in previous command and redo it. |
| <code>:his</code>  | List the commands history.                                          |

The optional integer argument *n* for `:s` means do `:s n` times.

**Note:** `step` is a Listener-based form stepper. LispWorks also offers a graphical source-code Stepper tool. See the *LispWorks IDE User Guide* for details of that.

## Examples

The following examples illustrate some of these commands.

```

USER 12 > (step (+ 1 (* 2 3) 4))
(+ 1 (* 2 3) 4) -> :s
  1 -> :s
  1
  (* 2 3) -> :su
  6
  4 -> :s
  4
11
11

USER 13 > (defun foo (x y) (+ x y))
FOO

```

```

USER 14 > step (foo (+ 1 1) 2)
(FOO (+ 1 1) 2) -> :st
  (+ 1 1) -> :s
    1 -> :s
    1
    1 -> :s
    1
    2
    2 -> :s
    2
    4
    4

USER 15 > :redo (STEP (FOO # 2))
(FOO (+ 1 1) 2) -> :s
  (+ 1 1) -> :s
    1 -> :s
    1
    1
    2
    2 -> :s
    2
    (+ X Y) -> :s
      X -> :s
      2
      Y -> :s
      2
      4
      4
      4

```

You can interact when an evaluated form returns, by setting the variable `*no-step-out*` to `nil`. The prompt changes as shown below:

```

USER 36 > step (cons 1 2)
(CONS 1 2) -> :s
  1 -> :s
  1 = 1 <- :sr 3
  2 -> :s
  2 = 2 <- :sr 4
  (CONS 1 2) = (3 . 4) <- :s
  (3 . 4)

```

To allow expansion of macros, set the variable `*step-macros*` to `t`.

To step through the function calls in compiled code, set the variable `hcl:*step-compiled*` to `t`.

If required, the stepper can print out the step level: set the variable `*print-step-level*` to `t`, as shown in this session:

```
USER 21 > (setq *print-step-level* t)
T
USER 22 > step (cons 1 2)
[1] (cons 1 2) -> :s
[2]   1 -> :s      1
[2]   2 -> :s
      2
      (1 . 2)
(1 . 2)
```

It is not advisable to try to step certain compiled functions, such as `car` and `format`. The variable `hcl:*step-filter*` contains a list of functions which should not be stepped. If you get deep stack overflows inside the stepper, you may need to add a function name to `hcl:*step-filter*`.

By default, the stepper uses the same printing environment as the rest of LispWorks (the same settings of the `*print-...*` variables). To control the stepper printing environment independently, set the variable `hcl:*step-print-env*` to `t`.

The values of the variables `hcl:*step-print-...*` are then used instead of the variables `*print-...*`.

## stream-element-type

## *Generic Function*

Summary      Implements `stream-element-type` as a generic function.

Package      `common-lisp`

Signature      `stream-element-type stream => type`

Arguments      `stream`                  A stream.

|             |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>type</i> | A type specifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description |             | <p>The function <code>stream-element-type</code> is implemented as a generic function. Depending on the stream, a method should be defined for this generic function that returns the element type of the stream.</p> <p>Methods must be implemented for all subclasses of <code>buffered-stream</code>. Typically for character streams, the implementation can return the <code>array-element-type</code> of the buffer.</p> <p>For the class <code>fundamental-character-stream</code> a default method is provided which returns <code>character</code>. A method should be defined for stream classes based on the <code>fundamental-binary-stream</code> class.</p> <p>There is an example in “Recognizing the stream element type” on page 400.</p> |
| See also    |             | <code>buffered-stream</code><br><code>fundamental-binary-stream</code><br><code>fundamental-character-stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|           |                     | Type                                                                                                                               |
|-----------|---------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Summary   |                     | The string type.                                                                                                                   |
| Package   |                     | <code>common-lisp</code>                                                                                                           |
| Signature |                     | <code>string length element-type</code>                                                                                            |
| Arguments | <i>length</i>       | The length of the string (or <code>*</code> , meaning any).                                                                        |
|           | <i>element-type</i> | The type of string element. The default is the value of <code>*default-character-element-type*</code> rather than <code>*</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The union of all string types as specified in the standard, but extended with an extra parameter: <i>element-type</i> .<br><br>$(\text{string} \ length \ \text{element-type})$ means all string types whose element type is a subtype of <i>element-type</i> . That is:                                                                                 |
|             | <pre>(string * base-char)      = (vector base-char *)<br/><br/>(string * lw: bmp-char) = (or (vector base-char *)<br/>                           (vector lw: bmp-char *))<br/><br/>(string * character)     = (or (vector base-char *)<br/>                           (vector lw: bmp-char *)<br/>                           (vector character *))</pre> |
| Example     | <pre>CL-USER 235 &gt; (lw: set-default-character-element-type<br/>                  'base-char)<br/>BASE-CHAR<br/>CL-USER 236 &gt; (concatenate 'string "f" "o" "o")<br/>"foo"<br/>CL-USER 237 &gt; (type-of *)<br/>SIMPLE-BASE-STRING</pre>                                                                                                             |
| See also    | <b>*default-character-element-type*</b><br><b>set-default-character-element-type</b><br><b>simple-string</b>                                                                                                                                                                                                                                             |

|           | <i>Macro</i>                                                        |
|-----------|---------------------------------------------------------------------|
| Summary   | Determines the execution time of a form in the current environment. |
| Package   | <code>common-lisp</code>                                            |
| Signature | <code>time form =&gt; result</code>                                 |
| Arguments | <i>form</i> A form to be evaluated.                                 |
| Values    | <i>result</i> The result of the evaluation of the form.             |

**Description** `time` can be used to determine execution times. The macro evaluates the form *form* and returns its value *result*. `time` also prints some timing and size data: *user time*, *system time*, *elapsed time*, and the total amount of heap space allocated in executing the form (in bytes).

The *user time* printed is the time used by LispWorks or any code that it calls in a dynamic library.

The *system time* printed is the time used in the operating system kernel when it is doing work on behalf of the LispWorks process.

The *elapsed time* printed is the time you could in principle measure with a stopwatch.

If LispWorks is 100% busy throughout the execution of the code, then *user time* + *system time* = *elapsed time*.

Each of the times is printed as:

- *secs.micros* if less than 60 seconds
- *hours:minutes:secs.micros* if 60 seconds or more.

The timing and size data covers all stack groups, not just the one that invokes `time`.

**Notes**

1. Note that `time` itself uses a small, constant amount of heap space.
2. `time` measures all threads, so to test accurately for consing in *code* you need to do:  
`(sys:with-other-threads-disabled (time code))`  
This is particularly important when using the LispWorks IDE. Do not use `with-other-threads-disabled` in your application code.

Examples

```
CL-USER 7 > (time (loop for i below 3000000
                           sum (sqrt i)))
Timing the evaluation of (LOOP FOR I BELOW 3000000 SUM
(SQRT I))

User time      =  0:01:04.187
System time    =        0.062
Elapsed time   =  0:01:07.297
Allocation     = 4932022956 bytes
0 Page faults
Calls to %EVAL    72000048
3.4606518E9
```

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>trace</b> | <i>Macro</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Summary      | Invoke the Common Lisp tracing facility on the named functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Package      | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature    | <code>trace {function-name tracing-desc}* =&gt; trace-result</code><br><code>tracing-desc ::= (function-dspec {keyword form}*)</code><br><code>keyword ::= :after   :allocation   :before   :backtrace  </code><br><code>           :eval-after   :eval-before   :break  </code><br><code>           :break-on-exit   :entrycond   :exitcond  </code><br><code>           :inside   :process   :trace-output   :step  </code><br><code>           :when</code><br><code>qualifier ::= :after   :before   :around</code><br><code>function-name ::= symbol   (setf symbol)</code> |

|           |                       |                                                                                                                                                             |
|-----------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments | <i>function-name</i>  | A symbol whose symbol-function is to be traced, or a <code>setf</code> function name. Functions, macros and generic functions may be specified this way.    |
|           | <i>function-dspec</i> | A function-dspec as described in “Function dspecs” on page 84, which apart from symbols, can specify methods, <code>setf</code> functions and subfunctions. |
|           | <i>tracing-desc</i>   | Specifies the functional definition which is to be traced and specifies any additional options that are required.                                           |

**:after** is followed by a list of forms; these are evaluated upon returning from the function. The values of these forms are also printed out by the tracer. The forms are evaluated after printing out the results of the function call, and if they modify `hcl:*traced-results*` then the values received by the caller of the function are correspondingly altered (see also `hcl:*traced-results*`).

**:allocation** — if non-nil, the memory allocation made during a function-call is printed upon exit from the function. This allocation is counted in bytes. If it is any other symbol (except `nil`), `trace` uses the symbol to accumulate the amount of allocation made between entering and exiting the function. Upon exit from the function, the symbol contains the number of bytes allocated during the function-call. For example,

```
(trace (print :entrycond nil
              :exitcond nil
              :allocation $$print-allocation))
```

results in `$$print-allocation` containing the sum of the allocation made inside `print`.

Note that if the function is called again, `trace` continues to use `$$print-allocation` as an accumulator of memory allo-

cation. It adds to the present value rather than re-initializing it each time the function is called.

**:backtrace** generates a backtrace on each call to the traced function. It is followed by a keyword that can be any of the following values:

- :quick** Like the **:bq** debugger command.
- t** Like the **:b** debugger command.
- :verbose** Like the **:b :verbose** debugger command.
- :bug-form** Like the **:bug-form** debugger command.

**:before** is followed by a list of forms; these are evaluated upon entering the function and their values are printed out by the tracer. The forms are evaluated after printing out the arguments to the function, and if they alter **\*traced-arglist\*** then the values received by the body of the function are changed accordingly (see also **\*traced-arglist\***).

**:eval-after** and **:eval-before** are similar to **:after** and **:before**, without output.

**:break** is followed by a form. This is evaluated after printing the standard information caused by entering the function, and after executing any **:before** forms; if it returns **nil** then tracing continues normally, otherwise **break** is called. This provides a way of entering the debugger through the tracer.

**:break-on-exit** is followed by a form. This is evaluated after printing the standard information caused by returning from the function, and before executing any **:after** forms; if it returns **nil** then tracing continues normally, otherwise **break** is called. This provides a second way of entering the debugger through the tracer.

**:entrycond** controls the printing of the standard entry message (including the function's arguments). If the form following it evaluates to give a non-nil value when the function is entered, then the entry message is printed (but otherwise it is not). If this option is not present then the standard entry mes-

sage is always printed upon calling the function. See also the `:when` option.

`:exitcond` controls the printing of the standard exit message (including the function's results). If the form following it evaluates to give a non-nil value when the function is exited, then the exit message is printed (but otherwise it is not). If this option is not present then the standard exit message is always printed upon returning from the function. See also the `:when` option.

`:inside` restricts the tracing to within one of the functions given as an argument. A single symbolic function name is treated as a list of one element. For example, `:inside format` is equivalent to `:inside (format)`.

`:process` may be used to restrict the tracing to a particular process. If it is followed by a process then the function is only traced when it is invoked from within that process. If it is followed by `t` then it is traced from all processes — this is the default. In any other cases the function is not traced at all.

`:trace-output` should be followed by a stream. All the output from tracing the function is sent to this stream. By default output from the tracer is sent to `*trace-output*`. Use of this argument allows you to dispatch traced output from different functions to different places.

`:step`, when non-nil, invokes the stepper (for evaluated functions).

`:when` overrides all other keywords. It is followed by an expression, and tracing only occurs when that expression evaluates to non-nil. It is useful if you want to combine `:entrycond` and `:exitcond`.

|        |                           |                                                                                                                                                     |
|--------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Values | <code>trace-result</code> | If <code>trace</code> is called with no arguments then it returns a list of the names of all the functions currently being traced. When called with |
|--------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

one or more arguments, it returns the symbols of the functions specified in those arguments.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>trace</code> is the macro used to invoke the tracing facility. This is a useful debugging tool that enables information about selected calls to be generated by the system. The standard way of invoking <code>trace</code> is to call it with the names of the functions, macros and methods that are to be monitored in this way. Calls to these produce a record of the function that was called, the arguments it received and the results it produced.</p> <p>The arguments to <code>trace</code> each specify a function (or a macro or a method) to be traced. They may also contain further instructions to control how the tracing output is displayed, or to cause particular actions to occur when the functions is called or exited. If <code>trace</code> is called with a function that is already being traced, then the new tracing specification for that function replaces the old version.</p> |
| Notes       | <p>For detailed information about the current tracing state, call <code>tracing-state</code>.</p> <p>For information about problems with tracing and their resolution, see “Troubleshooting tracing” on page 60.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Example 1

```

USER 1 > (defvar *number-of-calls-to-max* 0)
*NUMBER-OF-CALLS-TO-MAX*

USER 2 > (trace (max :after
                      ((incf *number-of-calls-to-max*))))
(MAX)

USER 3 > (dotimes (i 2) (max i 1))
0 MAX > (0 1)
0 MAX < (1)
1
0 MAX > (1 1)
0 MAX < (1)
2
NIL

USER 4 > *number-of-calls-to-max*
2

USER 5 > (trace (max
                  :entrycond
                  (> (length compiler:*traced-arglist*)
                      2)
                  :exitcond nil))
(MAX)

USER 6 > (max 2 3 (max 4 5))
0 MAX > (2 3 5)
5

```

## Example 2

This example illustrates the use of `:inside`.

```

CL-USER 2 > (defun outer ()
              (inner))
OUTER

CL-USER 3 > (defun inner ()
              10)
INNER

CL-USER 4 > (trace (inner :inside outer))
              ;, only trace when inside OUTER
(INNER)

CL-USER 5 > (inner)
              ;, no tracing occurs since we are not inside OUTER
10

CL-USER 6 > (outer)    ;, INNER is traced inside OUTER
0 INNER > NIL
0 INNER < (10)
10

CL-USER 7 >

```

Example 3 To trace a method:

```

(defmethod foo (x) x)

(trace ((method foo (t))))

```

Example 4 To trace a setf function:

```

CL-USER 56 > (defvar *a* 0)
*A*

CL-USER 57 > (defun (setf foo) (x y) (set y x))
(SETF FOO)

CL-USER 58 > (trace (setf foo))
((SETF FOO))

CL-USER 59 > (setf (foo '*a*) 42)
0 (SETF FOO) > (42 *A*)
>> X : 42
>> Y : *A*
0 (SETF FOO) < (42)
42

```

| <b>truename</b> | <i>Function</i>                                                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary         | Returns the truename of a pathname.                                                                                                                                                                                                      |
| Package         | <code>common-lisp</code>                                                                                                                                                                                                                 |
| Signature       | <code>truename <i>filespec</i> =&gt; <i>truename</i></code>                                                                                                                                                                              |
| Arguments       | <code>filespec</code> A pathname designator.                                                                                                                                                                                             |
| Values          | <code>truename</code> A fully-specified physical pathname.                                                                                                                                                                               |
| Description     | <p>The function <code>truename</code> behaves as specified in ANSI Common Lisp. The returned value is a fully-specified pathname. Truenames are always fully-specified in LispWorks (this prevents them from ever being corrupted by</p> |

`*default-pathname-defaults*`). Note that this means that the paths returned by `directory` are always fully specified.

| Values               | When called with no arguments, it returns the symbols of all functions currently being traced. When called with one or more functions as arguments, <code>untrace</code> returns a list of the symbols of those functions. Thus, in all situations, <code>untrace</code> returns a list of the symbols of those functions being untraced.                |                      |                                                           |                    |                                                                                                                   |
| Description          | <code>untrace</code> is used to cease the tracing of functions. If it is called with no arguments then the tracing of all currently traced functions is stopped. If it is called with one or more symbols then the tracing of those functions is stopped. A warning is given if <code>untrace</code> is called with a function that is not being traced. |                      |                                                           |                    |                                                                                                                   |
| Examples             | <pre>USER 12 &gt; (progn (untrace) (trace + - / *))</pre> <code>*</code>                                                                                                                                                                                                                                                                                 |                      |                                                           |                    |                                                                                                                   |

```

USER 13 > (+ 2 3)
0 + > (2 3)
0 + < (5)
5

USER 14 > (untrace + -)
(* |/|)

USER 15 > (+ 2 3)
5

```

To untrace a method:

```
(untrace (clos:method foo (t)))
```

## update-instance-for-different-class

## *Generic Function*

Summary

As specified for Common Lisp, and locks the redefined instance.

Package

**common-lisp**

Description

The generic function **update-instance-for-different-class** behaves as specified for ANSI Common Lisp.

During the operation of updating the instance, including the call to **update-instance-for-different-class**, the redefined instance is locked against access. Any other process that tries to access the instance will hang until the operation finishes. Therefore your methods must avoid doing anything that may wait for another process which may access the instance, as this would cause a deadlock.

## **with-output-to-string** *Macro*

|             |                                                                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Creates a character output stream, performs a series of operations that may send results to this stream, and then closes the stream.                                                                                                  |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                              |
| Signature   | <code>with-output-to-string (var &amp;optional string-form &amp;key element-type) declaration form =&gt; result</code>                                                                                                                |
| Description | The macro <code>with-output-to-string</code> behaves as specified in the ANSI Common Lisp Standard with one exception: the default value of <code>element-type</code> is the value of <code>*default-character-element-type*</code> . |

Therefore for strict compliance you must call `set-default-character-element-type` to set the default string type to `character`.

## The COMPILER Package

This chapter describes symbols available in the `COMPILER` package.

The compiler is discussed in detail in Chapter 9, “The Compiler”.

| <b>deftransform</b> |                                                                                                   | <i>Macro</i>                                                                                                                                                        |
|---------------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary             | Defines a function that computes the expansion of a form.                                         |                                                                                                                                                                     |
| Package             | <code>compiler</code>                                                                             |                                                                                                                                                                     |
| Signature           | <code>deftransform name transform-name lambda-list &amp;body body =&gt; list-of-transforms</code> |                                                                                                                                                                     |
| Arguments           | <i>name</i>                                                                                       | A symbol naming the function to which the transform is to be applied.                                                                                               |
|                     | <i>transform-name</i>                                                                             | The symbol naming the transformation — it should be unique for the function being transformed — and provides a handle with which to redefine an existing transform. |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>lambda-list</i> | This must match against the form being expanded before expansion is allowed to take place, in the sense that it must be valid to call a function with such a lambda list using the arguments supplied in the candidate-form for expansion.                                                                                                                                                                                                                                                                                         |
| <i>body</i>        | The body of the expander function, the result of which replaces the original form (unless it evaluates to <code>compiler::%pass%</code> , in which case no transformation is applied).                                                                                                                                                                                                                                                                                                                                             |
| Values             | <i>list-of-transforms</i> A list of the names of transforms defined for the function, including the one just added.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description        | <code>deftransform</code> , like <code>defmacro</code> , defines a function that computes the expansion of a form. Transforms are only used by the compiler and not by the interpreter. <code>deftransform</code> allows you to add to the optimizations performed by the compiler.                                                                                                                                                                                                                                                |
| Examples           | <pre>(compiler:deftransform +  +-of-2  (x y)   '(system:: +2  ,x ,y)) (compiler:deftransform +  +-of-many (x &amp;rest y)   '(system:: +2  ,x (+ ,@y)))  ;; now an expression like (+ a b c 4 5 7 d e f) ;; compiles to use the binary version ;; of + (inlined by default), ;; rather than the full (slow) version of + (compiler:deftransform list  list-of-1 (x)   '(cons ,x '()))  (compiler:deftransform list  list-of-2 (x y)   '(cons ,x (cons ,y '())))  ;; save having to call list - ;; cons is inlined by default</pre> |

```

(compiler:deftransform constant my-trans (x)
  (cond ((constantp x) x)
        ((consp x) '(quote ,(eval x)))
        (t 'compiler::%pass%)) ; give up if not a
cons

(compile (defun three-list () (constant (list 1 2 3)))))

;; the function three-list returns the
;; same list (1 2 3)
;; every time it is called...

```

The `list-of-2` example returns

```
(LIST-OF-2 LIST-OF-1 COMPILER::LIST-TRANSFORM)
```

as its result, since a similar transform already exists in the compiler, by the name `compiler::list*-transform`.

#### Notes

`deftransform` differs from `defmacro` in various ways:

The evaluation of the body can return `compiler:%pass%` indicating that the form is not to be expanded (in other words, the transform method has elected to give up trying to improve the code).

The compiler only calls the expander function if the arguments match the lambda list — macros are unconditionally expanded.

There can be several `deftransforms` for the same symbol, each having a different name. (The compiler calls each one in turn until one succeeds. This repeats until they all pass, so that the replacement form may itself be transformed.)

If a transform takes keyword arguments the compiler preserves the correct order of evaluation.

A carelessly written `deftransform` may lead the compiler to transform valid Common Lisp into incorrect code — there is no semantic checking of the transform.

## The DBG Package

This chapter describes symbols available in the `DBG` package, used to configure the debugging information produced by LispWorks.

The debugger is discussed in detail in Chapter 3, “The Debugger”.

| <b>close-remote-debugging-connection</b> |                   | <i>Function</i>                                                                                                                                                                                                                                                                                                |
|------------------------------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                                  |                   | Close the remote debugging connection.                                                                                                                                                                                                                                                                         |
| Package                                  |                   | <code>dbg</code>                                                                                                                                                                                                                                                                                               |
| Signature                                |                   | <code>close-remote-debugging-connection <i>connection</i></code>                                                                                                                                                                                                                                               |
| Arguments                                | <i>connection</i> | A <code>remote-debugging-connection</code> .                                                                                                                                                                                                                                                                   |
| Description                              |                   | The function <code>close-remote-debugging-connection</code> performs all the close cleanup operations that were associated with <i>connection</i> by <code>remote-debugging-connection-add-close-cleanup</code> , closes the underlying stream and clears any other resources that <i>connection</i> is using. |

`close-remote-debugging-connection` may be called on either side (IDE or client) and causes the other side of the connection to call `close-remote-debugging-connection` on its own side.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p><code>close-remote-debugging-connection</code> is called automatically by LispWorks when the other side closes the connection. It is also called automatically after you call <code>configure-remote-debugging-spec</code> with <code>:setup-default nil</code> when the Debugger or Remote Listener window is closed.</p> <p>During debugging, you probably do not need to worry about closing connections, but if you use the remote debugging connections for other purposes then you will probably need to ensure they are closed, because each connection uses a process as well as some other resources.</p> |

| Description | <p>The function <code>configure-remote-debugging-spec</code> tells LispWorks how to open a connection for remote debugging on the client side if there is no existing connection to use (see <code>set-remote-debugging-connection</code> for details). <code>configure-remote-debugging-spec</code> changes the global settings, unless it is called inside the dynamic extent of <code>with-remote-debugging-spec</code>, in which case its effects last until the exit from this extent (except for <code>setup-default</code> and <code>enable</code>, see below).</p> <p>If <i>port</i>, <i>log-stream</i>, <i>failure-function</i>, <i>timeout</i>, <i>open-callback</i> or <i>name</i> are supplied then they configure the corresponding settings, otherwise the settings are not changed.</p> <p><i>host</i> and <i>port</i> configure the hostname and TCP port to connect to (see the <i>hostspec</i> and <i>service</i> arguments to <code>open-tcp-stream</code>). <i>host</i> can also be <code>nil</code>, which specifies that LispWorks must not try to open a debugging connection. The initial configured value of <i>port</i> is the value of <code>*default-ide-remote-debugging-server-port*</code>, which is 21101 initially.</p> <p><i>timeout</i> configure the timeout in seconds, or <code>nil</code> for indefinite. If a connection to the IDE side cannot be made within the specified timeout then remote debugging is not used.</p> |                                                                                     |

*log-stream* configures logging for communication problems, including failure to open the connection (unless the configured value of *failure-function* is non-nil) and errors when communicating across the connection. Failure to open the stream can happen if the host is not ready, the communication is blocked or the network/host are overloaded. Later failures should not happen as long as the underlying operating system is not broken. When the configured value of *log-stream* is non-nil, LispWorks writes error messages to it. Otherwise (the default) LispWorks does not log errors when communicating across the connection.

When the configured value of *failure-function* is non-nil, it will be called with the values of *host* and *port* in case of failure to open the connection, instead of writing to *log-stream*. The initial value of *failure-function* is `nil`.

The configured value of *name* is used as the name of the connection. It affects how the connection object is printed and also the name of the Lisp process that handles communication for the connection. It initially defaults to "Remote debugging".

When the configured value of *open-callback* is non-nil, it is called after the new connection has been opened, with the new connection as its argument. The initial configured value of *open-callback* is `nil`.

*setup-default* and *enable* determine whether the new connection becomes the default, and when it should be used. Note that they always have a global effect, even when `configure-remote-debugging-spec` is called in the dynamic extent of `with-remote-debugging-spec`.

When *setup-default* is `:delayed` (the default if the configured *open-callback* is `nil`) or `t`, the new connection will become the default connection, by a call to `set-default-remote-debugging-connection`. If *enable* is non-nil (the default), then the enabling switch is turned on as if by calling `set-remote-debugging-connection` with argument `t`. As a

result, assuming no other calls to `set-remote-debugging-connection` or `set-default-remote-debugging-connection` are made, the new connection will be used in the future whenever a connection is needed. See `set-remote-debugging-connection` for more details. If `setup-default` is `:delayed`, then the connection will be opened the first time it is needed. If `setup-default` is `t`, then `configure-remote-debugging-spec` opens the connection immediately. Thus with the default arguments, the connection will be opened the first time it is needed, and will then be used whenever a connection is needed.

When `setup-default` is `nil` (the default if the configured `open-callback` is non-`nil`), the connection is not made a default. If it is created when entering the debugger or for a Remote Listener, then it will be closed automatically when exiting the debugger or closing the Listener. See `remote-inspect` for how it deals with connections.

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | <p>For the connection to open successfully, the machine which is addressed by <code>host</code> must be listening for TCP connections on <code>port</code>. Normally that should happen as result of calling <code>start-ide-remote-debugging-server</code>, but you can reasonably easily write your own version of it if required.</p> <p>Using <code>configure-remote-debugging-spec</code> requires the ability to use <code>open-tcp-stream</code>, which at OS level means using the C library function <code>connect</code>.</p> <p>Sometimes it is easier to make the connection in the other direction. For example, the Android SDK allows you to redirect sockets from a host to the android device, by using <code>adb forward</code>, so when the Android device is the client side, it is easier to connect the other way, in which case you should use <code>start-client-remote-debugging-server</code> on the client side (instead of using <code>configure-remote-debugging-spec</code>), and call <code>ide-connect-remote-debugging</code> on the IDE side.</p> |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Opening a connection once and then re-using it is probably more efficient in most cases and also has the advantage that remote object handles remain valid. However, if opening a connection is relatively rare, using one-off connections removes the (quite small) overhead of keeping a connection open.

When you do not re-use the connection, the configured values are used each time you open a connection.

If you wish to open a connection yourself, then note that you cannot implement the delayed automatic opening that `configure-remote-debugging-spec` implements when `setup-default` is `:delayed` (the default) or `nil`. You can, however, implement the equivalent of `:setup-default t` (that is opening the connection before it is needed) by making the underlying stream yourself using `open-tcp-stream` or some other mechanism, using `create-client-remote-debugging-connection` to create the client connection and then using `set-default-remote-debugging-connection`, `set-remote-debugging-connection` and `with-remote-debugging-connection` as appropriate.

| Description | <p>The function <code>create-client-remote-debugging-connection</code> creates a client side remote debugging connection. The function <code>create-ide-remote-debugging-connection</code> creates an IDE side remote debugging connection.</p> <p>Normally you would use the higher level interface functions <code>start-client-remote-debugging-server</code> or <code>configure-remote-debugging-spec</code> to open a client side connection, and <code>start-ide-remote-debugging-server</code> or <code>ide-connect-remote-debugging</code> to open an IDE side connection. The higher level functions call these functions to create the connection.</p> <p><i>name</i> specifies a name for the connection, but otherwise does not affect its behavior. On the IDE side it is used in the title of Remote Listener and Remote Debugger tools. On both sides it is used in the name of the process that handles communication across the connection.</p> <p>Either <i>socket</i> or <i>stream</i> (but not both) must be non-nil.</p> |                                                                                              |

If *socket* is non-nil, it must be a socket handle, like the one that `start-up-server` passes to its *function* argument or the socket that `accept-tcp-connections-creating-async-io-states`, when called with `:create-state nil`, passes to its *connection-function*. A `socket-stream` is created with this socket and used as the stream in the connection. *socket* defaults to `nil`.

If *stream* is non-nil, it must be an `base-char` stream opened for `:io` and it is used directly in the connection. Typically it will be a `socket-stream`, but that is not a requirement. *stream* defaults to `nil`.

If *ssl* is non-nil, then `attach-ssl` is called on the stream, passing *ssl* as the `:ssl-ctx` argument. Note that this will work only if the stream is a `socket-stream`. *ssl* defaults to `nil`.

*log-stream*, if non-nil, must be an output stream. The connection writes messages to it in situations when communication fails. *log-stream* defaults to `nil`.

For the connection to work, the other side of the socket or stream must be the opposite kind of connection, that is for a client side connection the other side needs to be an IDE connection and vice versa.

The "ownership" of *socket* or *stream* is transferred to the connection by these functions. That means that no further I/O operations are allowed on *socket* or *stream* by other code, and they must not be closed. They will be closed when the connection is closed.

The value of *client-side-connection* that is returned by `create-client-remote-debugging-connection` can be used as the *connection* argument to `with-remote-debugging-connection`, `set-remote-debugging-connection` or `set-default-remote-debugging-connection`, or as the `:connection` keyword to `start-remote-listener` or `remote-inspect`. It is not remembered by LispWorks anywhere.

The value of *ide-side-connection* that is returned by `create-ide-remote-debugging-connection` is remembered by LispWorks, and is returned by `ide-list-remote-debugging-connections` or `ide-find-remote-debugging-connection` when appropriate. As a result, it may be used by any of the IDE side functions. It can also be passed explicitly to any of these functions. It is forgotten when it is closed.

Both *client-side-connection* and *ide-side-connection* can be manipulated by these functions:

- `close-remote-debugging-connection` closes it.
- `remote-debugging-connection-add-close-cleanup` adds a cleanup callback that is called when the connection is closed.
- `remote-debugging-connection-peer-address` finds the peer address of the connection.
- `remote-debugging-connection-name` returns its name.
- `ensure-remote-debugging-connection` checks if it is still open.

| Description                 | This variable is used to control the number of components of an object which are printed during output from the debugger. If its value is a positive integer then the components up to that number are printed. If it is <code>nil</code> then all the parts of an object are shown.                                                                                                                            |                 |
| Examples                    | <pre>USER 83 &gt; (setq dbg:*debug-print-length* 3)  3 USER 84 &gt; (aref   '(1 2 3 4 "Jenny" "cottage" "door")   2)  Error: (1 2 3 4 Jenny cottage door) must be        an array 1 (abort) return to top loop level 0.  Type :c followed by a number to proceed  USER 85 : 1 &gt; :v Call to ARRAY-ACCESS : Arg 0 (ARRAY) : (1 2 3 ...) Arg 1 (SUBSCRIPTS) : (2) Arg 2 (SET-P) : NIL Arg 3 (VALUE) : NIL</pre> |                 |
| Notes                       | <code>*debug-print-length*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                               |                 |

| Initial value | <code>4</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description   | <code>dbg:*debug-print-level*</code> controls the depth to which nested objects are printed during output from the debugger. If its value is a positive integer then components at or above that level are printed. By definition an object to be printed is considered to be at level 0, its components are at level 1, their subcomponents are at level 2, and so on. If <code>dbg:*debug-print-level*</code> is <code>nil</code> then objects are printed to arbitrary depth.        |
| Example       | <pre>USER 89 &gt; (setq dbg:*debug-print-level* 2) 2 USER 90 &gt; (subseq 3 '(cat (dog) ((goldfish)                                   (((hamster)))))  Error: Illegal START argument (CAT (DOG)                                ((GOLDFISH))                                (((HAMSTER)))) 1 (abort) return to top loop level 0.  Type :c followed by a number to proceed  USER 91 : 1 &gt; :v Call to CHECK-START-AND-END : Arg 0 (START) : (CAT (DOG) (#) (#)) Arg 1 (END) : NIL</pre> |
| Notes         | <code>*debug-print-level*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## ensure-remote-debugging-connection *Function*

|             |                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Ensures that an object is a working remote debugging connection.                                                                                                                                                                                                                                                                            |
| Package     | <code>dbg</code>                                                                                                                                                                                                                                                                                                                            |
| Signature   | <code>ensure-remote-debugging-connection object =&gt; connection-or-nil</code>                                                                                                                                                                                                                                                              |
| Arguments   | <i>object</i> An object.                                                                                                                                                                                                                                                                                                                    |
| Values      | <i>connection-or-nil</i> A <code>remote-debugging-connection</code> or <code>nil</code> .                                                                                                                                                                                                                                                   |
| Description | The function <code>ensure-remote-debugging-connection</code> checks that <i>object</i> is a remote debugging connection (either IDE or client side) and that it is opened, and if so returns it. Otherwise it returns <code>nil</code> .                                                                                                    |
| Notes       | The main purpose of <code>ensure-remote-debugging-connection</code> is to check that the connection is still open. Debugging connections may close unexpectedly when the other side closes or the Lisp image quits or the machine is shut down, or (less likely) if something is wrong with the underlying connection between the machines. |
| See also    | “Remote debugging” on page 25                                                                                                                                                                                                                                                                                                               |

## executable-log-file *Function*

|         |                                        |
|---------|----------------------------------------|
| Summary | Returns the default bug form log file. |
|---------|----------------------------------------|

|             |                                                                                                                                                                                                                            |

### **\*hidden-packages\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | A list of packages whose symbols should not be displayed in debugger output.                                                                                                                                                                                                                                                                                                                 |
| Package       | <code>dbg</code>                                                                                                                                                                                                                                                                                                                                                                             |
| Initial value | A list containing the <code>dbg</code> and <code>conditions</code> packages.                                                                                                                                                                                                                                                                                                                 |
| Description   | <p><code>dbg:*hidden-packages*</code> is used by the debugger. It should be bound to a list of package specifiers. If a package is included in the list then any symbols in it are not shown by the debugger. Thus during backtraces the call frames corresponding to functions in these packages are not displayed. This can be useful in restricting the debugger to particular areas.</p> |

Example

```
CL-USER 1 > unbound

Error: The variable UNBOUND is unbound.
  1 (continue) Try evaluating UNBOUND again.
  2 Return the value of :UNBOUND instead.
  3 Specify a value to use this time instead of
evaluating UNBOUND.
  4 Specify a value to set UNBOUND to.
  5 (abort) Return to level 0.
  6 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or
?: for other options.

CL-USER 2 : 1 > :b 3
Call to ERROR
Call to EVAL
Call to CAPI::CAPI-TOP-LEVEL-FUNCTION

CL-USER 3 : 1 > (push "COMMON-LISP" dbg:*hidden-
packages*)
("COMMON-LISP" #<The COMPILER package, 3131/4096
internal, 41/64 external> #<The SYSTEM package,
6258/8192 internal, 1266/2048 external> "DBG"
"CONDITIONS")

CL-USER 4 : 1 > :b 3
Call to CAPI::CAPI-TOP-LEVEL-FUNCTION
Call to CAPI::INTERACTIVE-PANE-TOP-LOOP
Call to MP::PROCESS-SG-FUNCTION

CL-USER 5 : 1 >
```

Notes

1. \*hidden-packages\* can be set to *value* by  
`(set-debugger-options :hidden value)`
2. \*hidden-packages\* is an extension to Common Lisp.

| <i>stream</i>     | An output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |                   |                   |                                                            |
| <i>connection</i> | An <code>ide-remote-debugging</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |               |                   |                   |                                                            |
| Values            | <i>stream-remote-object</i> A remote object handle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                   |                   |                                                            |
| Description       | <p>The function <code>ide-attach-remote-output-stream</code> creates an output stream on the client side which is attached to <i>stream</i>, such that any output written to the output stream on the client side is sent to the IDE side and written to <i>stream</i>. The returned <i>stream-remote-object</i> is a remote object handle corresponding to a client side output stream.</p> <p><code>ide-attach-remote-output-stream</code> must be called on the IDE side.</p> <p><i>connection</i> can be used to specify which connection to use. If <i>connection</i> is <code>nil</code>, then <code>ide-find-remote-debugging-connection</code> is called to find a connection. See <code>ide-find-remote-debugging-connection</code> for more details about finding a connection.</p> <p><code>ide-attach-remote-output-stream</code> returns the same <i>stream-remote-object</i> if it is called again for the same <i>stream</i> and <i>connection</i>.</p> <p><i>stream-remote-object</i> is returned on the IDE side, but must be used on the client side, so you need to pass it to the client, normally by one of <code>ide-set-remote-symbol-value</code>, <code>ide-</code></p> |               |                   |                   |                                                            |

`funcall-in-remote` or `ide-eval-form-in-remote`. For example, you can call:

```
(dbg:ide-set-remote-symbol-value
  '*my-log-stream*
  (dbg:ide-attach-remote-output-stream
    mp:*background-standard-output*))
```

After this call, anything that is written to `*my-log-stream*` on the client side will appear in the background output in the IDE.

Notes      `ide-funcall-in-remote` and `ide-eval-form-in-remote` themselves use this mechanism to bind their *output-stream* around the evaluation/function call.

If there are any errors when writing to *stream*, they are reported to the *log-stream* of the IDE side connection (as specified by `ide-connect-remote-debugging` and `start-ide-remote-debugging-server`). Possible reasons for such errors are:

- Writing a non `base-char` to a `base-char` stream. *stream-remote-object* itself can handle any `character`, but if *stream* is a `base-char` stream then an error will be signaled if the client writes a non `base-char` into it.
- Writing to a file that fills the disk.
- Other I/O errors.

## ide-connect-remote-debugging

*Function*

Summary     IDE side: Connect to a client remote debugging server.

Package     `dbg`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                        |

| Description | <p>The function <code>ide-connect-remote-debugging</code> attempts to open a TCP stream to the client machine named by <code>host</code> on port number <code>port</code>. If this is successful within <code>timeout</code> seconds, then <code>create-ide-remote-debugging-connection</code> is called with the new stream, <code>log-stream</code> and a name constructed from <code>name</code>, <code>host</code> and a counter to create and return <code>connection</code>.</p> <p><code>port</code> defaults to the value of <code>*default-client-remote-debugging-server-port*</code>, which is 21102 initially.</p> <p><code>timeout</code> defaults to <code>nil</code>, which means waiting indefinitely (or until the operating system reports an error).</p> <p>If <code>open-a-listener</code> is non-nil, <code>ide-open-a-listener</code> is called to open a Remote Listener. <code>open-a-listener</code> defaults to <code>nil</code>.</p> |                                                        |
| Notes       | <p>The client machine (specified by <code>host</code>) must be accepting TCP connections on port number <code>port</code>, which would normally be done by calling <code>start-client-remote-debugging-server</code>. Normally you do not need to supply <code>port</code> because both <code>start-client-remote-debugging-server</code> and <code>ide-connect-remote-debugging</code> default it to the value of <code>*default-client-remote-debugging-server-port*</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                        |

The underlying TCP stream functionality must be working between the machines, that is they must be able to connect by TCP.

When using the Remote Debugger, Remote Listener or Inspector, you do not need to access the connection directly because the tools make one for you. In addition, `create-ide-remote-debugging-connection` remembers the connection, so all the IDE side functions that look for connections will find it.

You could easily implement your own version of `ide-connect-remote-debugging` if needed using `open-tcp-stream` and `create-ide-remote-debugging-connection`.

The editor command `Connect Remote Debugging` calls `ide-connect-remote-debugging`.

### `ide-eval-form-in-remote`

### `ide-funcall-in-remote`

### `ide-set-remote-symbol-value`

### *Functions*

Summary      IDE side: Evaluate a Lisp form, call a function or set a variable, all on the client side.

Package      `dbg`

Signature      `ide-eval-form-in-remote form &key encoded-result timeout connection output-stream force-simple => results`

`ide-funcall-in-remote func-and-args &key encoded-result timeout connection output-stream => results`

`ide-set-remote-symbol-value symbol value &key connection => value`

|             | <i>value</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | An object.                                                                                                                                            |
| Values      | <i>results</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | The values returned by evaluating the form or calling the function, or the two values <code>nil</code> and <code>:timeout-waiting-for-remote</code> . |
|             | <i>value</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | An object.                                                                                                                                            |
| Description | <p>The function <code>ide-eval-form-in-remote</code> evaluates <i>form</i> on the client side and returns the result(s). Evaluation is done by <code>(eval form)</code>, unless either the evaluator has been eliminated (delivery with <code>:keep-eval nil</code>) or <i>force-simple</i> is non-nil, in which case a (very) simple evaluator is used. The simple evaluator recognizes symbols and conses, and returns all other objects. For a symbol, it returns the symbol-value (not recognizing symbol-macros). For a cons, if the car is one of <code>quote</code>, <code>if</code> or <code>progn</code> then it uses the Common Lisp semantics (using itself for recursion), otherwise it uses itself to evaluate all the elements of the cons's cdr and applies the car to those values.</p> <p>The function <code>ide-funcall-in-remote</code> applies the car of <i>func-and-args</i> to the cdr of <i>func-and-args</i> and returns the result(s). Note that it does not do any evaluation of the elements of <i>func-and-args</i>.</p> |                                                                                                                                                       |

The function `ide-set-remote-symbol-value` calls `ide-funcall-in-remote` to set the client side *symbol* to *value* as in:

```
(dbg:ide-funcall-in-remote '(set symbol value)
                           :connection connection)
```

*encoded-result* affects how the results are represented, where an "encoded" object is represented as a remote object handle and an "unencoded" object is represented as a normal object on the IDE side. Numbers, characters and strings are always unencoded, and all other objects except symbols and conses are always encoded. The value of *encoded-result* affects symbols and conses as follows:

|                            |                                                                                                                                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nil</code> (default) | The top-level conses are unencoded, which means that a result that is a list is returned as an unencoded list on the IDE side. Symbols that are in packages that exist on the IDE side are returned as unencoded symbols. Note that non top-level conses are encoded. |
| <code>:symbols</code>      | The top-level conses are unencoded, but symbols and all other conses are encoded.                                                                                                                                                                                     |
| <code>:not-cons</code>     | All conses, and symbols that are in packages that exist on the IDE side, are unencoded.                                                                                                                                                                               |
| <code>t</code>             | All conses and symbols are encoded.                                                                                                                                                                                                                                   |

*timeout* determines how long to wait for the result(s). If the client side does not return result(s) within *timeout* seconds, then `ide-eval-form-in-remote` and `ide-funcall-in-remote` return the two values `nil` and `:timeout-waiting-for-remote`.

*connection* can be used to specify which connection to use. If *connection* is `nil`, then `ide-find-remote-debugging-connection` is called to find a connection. See `ide-find-remote-debugging-connection` for more details about finding a connection.

*output-stream* must be an output stream, and defaults to the value of `*standard-output*`. During the evaluation or call on the client side, the variables `*standard-output*`, `*error-output*` and `*trace-output*` are bound to a stream that sends anything that is written to it back to the IDE side where it is written to *output-stream*. This is done using `ide-attach-remote-output-stream` to create a client side stream.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p><i>form</i>, <i>func-and-args</i>, <i>symbol</i> and <i>value</i> are printed on the IDE side and read on the client side, and therefore must be objects that can be printed and read correctly. If the client is shaken (for example, delivered at level 2 or more), some symbols may not exist on the client side and will cause errors. If you want to ensure that specific symbols will work correctly with these functions, then use <code>deliver-keep-symbols</code> to keep them in the client.</p> <p>Any remote object handle inside any of <i>form</i>, <i>func-and-args</i>, <i>symbol</i> or <i>value</i> is replaced by the object itself on the client side.</p> |

| Description | <p>The function <b>ide-find-remote-debugging-connection</b> tries to find a useful IDE remote debugging connection. If <b>ide-set-default-remote-debugging-connection</b> was called, and the connection argument in the last call is still open, then <b>ide-find-remote-debugging-connection</b> returns this connection as <i>connection-or-nil</i> and <i>default-p</i> is <b>t</b>. Otherwise it returns the connection that was opened last and is still open as <i>connection-or-nil</i> and <i>default-p</i> is <b>nil</b>. If there are no opened connections then it returns <i>connection-or-nil</i> and <i>default-p</i> both as <b>nil</b>.</p> <p>The function <b>ide-set-default-remote-debugging-connection</b> sets the default connection that <b>ide-find-remote-debugging-connection</b> will return to <i>connection</i>. <i>connection</i> must be a valid IDE side remote debugging connection, that is an instance of <b>ide-remote-debugging</b> that is still open. You can obtain one by calling <b>create-ide-remote-debugging-connection</b>, <b>ide-find-remote-debugging-connection</b>, <b>ide-list-remote-debugging-connections</b> or <b>remote-object-connection</b>.</p> <p>The function <b>ide-list-remote-debugging-connections</b> returns a list of opened connections. If <i>match-string</i> is <b>nil</b>, the list contains all the connections. If <i>match-string</i> is non-<b>nil</b>, the</p> |

list contains only the connections whose name contains *match-string* as a substring (plain match, case-insensitive).

|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p><code>ide-find-remote-debugging-connection</code> is used by all the IDE side remote debugging interface functions like <code>ide-open-a-listener</code> and <code>ide-eval-form-in-remote</code> when their <i>connection</i> argument is <code>nil</code> (the default).</p> <p>The various Editor commands (starting with "Remote"), except those ending with "In Listener", use <code>ide-eval-form-in-remote</code>, and therefore also use <code>ide-find-remote-debugging-connection</code>. The Editor command <code>Set Default Remote Debugging Connection</code> uses <code>ide-list-remote-debugging-connections</code> and <code>ide-set-default-remote-debugging-connection</code>.</p> <p>The Remote Debugger and Remote Listener tools, and all remote object handles, are each associated with a specific connection, and therefore do not use <code>ide-find-remote-debugging-connection</code>.</p> <p><code>ide-find-remote-debugging-connection</code> and <code>ide-list-remote-debugging-connections</code> can find the connections because <code>create-ide-remote-debugging-connection</code> remembers each connection it creates. The higher level interface functions <code>start-ide-remote-debugging-server</code> and <code>ide-connect-remote-debugging</code> use <code>create-ide-remote-debugging-connection</code>.</p> |

| Description | <p>The function <code>ide-open-a-listener</code> opens a Remote Listener, by calling <code>start-remote-listener</code> on the client side of the connection.</p> <p>If <i>connection</i> is non-<code>nil</code>, it is used, otherwise <code>ide-open-a-listener</code> calls <code>ide-find-remote-debugging-connection</code> to find a connection. See <code>ide-find-remote-debugging-connection</code> for further details.</p> <p><i>timeout</i> specifies the length of time (in seconds) to wait before returning. <i>timeout</i> defaults to 10 and <code>nil</code> means waiting indefinitely.</p> <p>When successful, <code>ide-open-a-listener</code> returns <i>process-remote-object</i>, which is a remote object (see <code>remote-object-p</code>) corresponding to the client process object that runs the read-eval-print loop. When a timeout occurs, <i>process-remote-object</i> is <code>nil</code>.</p> |
| Notes       | When <i>process-remote-object</i> is <code>nil</code> it does not necessarily mean a failure and the Remote Listener may open later anyway. In particular, you can use <code>:timeout 0</code> to avoid any waiting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## log-bug-form Function

Summary Writes a log of an error. This is useful in an application’s error handlers.

Package `dbg`

Signature `log-bug-form description &key log-file message-stream => path`

Arguments `description` A string.

`log-file` A pathname designator.

`message-stream` An output stream, `t` or `nil`.

Values `path` A pathname.

Description The function `log-bug-form` is a simple interface for writing a log of an error. Your application’s error handlers can call it.

`log-bug-form` opens the file `log-file` for output. It writes the current date followed by a bug form. The bug form contains `description`, and debugging information generated by the system. When it finishes it writes to the stream `message-stream` a single line reporting that a bug form was written.

If `log-file` is supplied it must be a valid path, and it is used to open the file. The default value of `log-file` is the value returned by `executable-log-file`.

`log-bug-form` calls `ensure-directories-exist` before opening the log file, therefore so the directory where the `log-file` is written does not need to exist before `log-bug-form` is called.

If `message-stream` is `t` the message is written to standard output. If `message-stream` is a stream the message is written to it,

and if *message-stream* is `nil` then no message is written. *message-stream* defaults to the value of `*error-output*`.

If there is an error during the operation, `log-bug-form` silently fails and returns `nil`.

On success `log-bug-form` returns the path where the log file was written.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes               | <p><code>log-bug-form</code> is invoked automatically if the debugger decides to use the console (the terminal) rather than use the LispWorks IDE debugging tools. This means that after such an error the user can always find a bug form in the default log file, which can be found by using <code>executable-log-file</code>. <code>log-bug-form</code> always appends, so if it is called frequently the log file grows continuously. You may need to clear it periodically. It may be a good idea to move the file rather than delete it, so a record of errors remains.</p> <p>When editing the log file it should be noted that each bug form is preceded by the time it was written, and that the bug forms are in chronological order. That means that the interesting bug form is most often the last one in the file.</p> |
| Compatibility notes | In LispWorks 7.0 and earlier, <i>message-stream</i> defaulted to the value of <code>*debug-io*</code> , but this was not documented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| See also            | <code>executable-log-file</code><br><code>logs-directory</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|         | <i>Function</i>                                          |
|---------|----------------------------------------------------------|
| Summary | Returns the directory in which LispWorks puts log files. |
| Package | <code>dbg</code>                                         |

|             |                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>logs-directory =&gt; dir</code>                                                                                  |
| Values      | <code>dir</code> A directory pathname.                                                                                 |
| Description | The function <code>logs-directory</code> returns the directory in which LispWorks puts log files for the current user. |
| See also    | <code>executable-log-file</code><br><code>log-bug-form</code>                                                          |

## **output-backtrace** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Prints a backtrace of the current stack. For use in exception handling routines.                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| Package     | <code>dbg</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| Signature   | <code>output-backtrace keyword &amp;key stream printer-bindings</code>                                                                                                                                                                                                                                                                                                                                                                                                            |  |
| Arguments   | <p><code>keyword</code> Defines how verbose the output should be.<br/>           It can be one of <code>:quick</code>, <code>:brief</code>, <code>:verbose</code> or <code>:bug-form</code>, in increasing order of verbosity.</p> <p><code>stream</code> An output stream designator.</p> <p><code>printer-bindings</code> A list of conses.</p>                                                                                                                                 |  |
| Description | <p>The function <code>output-backtrace</code> prints a backtrace of the current stack.</p> <p>The output goes to the stream designated by <code>stream</code>. <code>printer-bindings</code>, if supplied, must be a list of conses, where the car of each cons is a symbol. <code>printer-bindings</code> is ignored if <code>keyword</code> is <code>:quick</code>. Otherwise, around the actual printing it binds each symbol to the value in the cdr of the cons. This is</p> |  |

intended to override the bindings that are used in the functions that `output-backtrace` uses.

`output-backtrace` should be used by applications in their exception handling routines to log a backtrace whenever an unexpected situation arises. In general, any application that is not intended to be used by Lisp programmers should have error handlers to deal with unexpected situations, and all these handlers should use `output-backtrace`.

|          |                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------|
| Notes    | The symbols that can be bound are not limited to "printer" symbols, so the name <i>printer-bindings</i> is slightly misleading. |
| See also | <code>log-bug-form</code>                                                                                                       |

## \*print-binding-frames\* *Variable*

|               |                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Controls whether binding frames are printed in debugger output.                                                                                                                                                                                                                             |
| Package       | <code>dbg</code>                                                                                                                                                                                                                                                                            |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                            |
| Description   | This variable is used by the debugger when it displays the stack frames. Binding frames are formed when special variables are bound, but are normally not shown by the debugger. However if the value of <code>dbg:*print-binding-frames*</code> is true then the binding frames are shown. |
| Notes         | <ol style="list-style-type: none"><li>1. <code>*print-binding-frames*</code> can be set to <i>value</i> by<br/><code>(set-debugger-options :bindings value)</code></li><li>2. <code>*print-binding-frames*</code> is an extension to Common Lisp.</li></ol>                                 |

## Example

```

CL-USER 16 > (defun print-to-length (object length)
    (let ((*print-length* length))
      (prinnt object)))
PRINT-TO-LENGTH

CL-USER 17 > (setf dbg:*print-binding-frames* t)
T

CL-USER 18 > (print-to-length '(x y z) 2)

Error: Undefined operator PRINNT in form (PRINNT
OBJECT) .
  1 (continue) Try invoking PRINNT again.
  2 Return some values from the form (PRINNT OBJECT) .
  3 Try invoking something other than PRINNT with the
same arguments.
  4 Set the symbol-function of PRINNT to another
function.
  5 Set the macro-function of PRINNT to another
function.
  6 (abort) Return to level 0.
  7 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

| Initial value | t                                                                                                                                                                                                                                                                                                                                                                                     |
| Description   | This variable is used by the debugger when it displays the stack frames. Catch frames are created when the special form <code>catch</code> is used. They are set up so that throws to the matching tag can be received. By default the debugger displays these frames, but if <code>*print-catch-frames*</code> is set to <code>nil</code> then the catch frames are no longer shown. |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## \*print-handler-frames\*

*Variable*

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| Summary       | Controls whether handler frames are printed in debugger output. |
| Package       | <code>dbg</code>                                                |
| Initial value | <code>nil</code>                                                |

Description This variable is used by the debugger when it displays the stack frames. Handler frames are created by error handlers (see “The stack in the debugger” on page 12), and are normally not shown by the debugger. However if `*print-handler-frames*` is set to `t` then the handler frames are displayed.

- Notes
1. `*print-handler-frames*` can be set to *value* by  
`(set-debugger-options :handler value)`
  2. `*print-handler-frames*` is an extension to Common Lisp.

Example

```
USER 162 > (setq lw:*print-handler-frames* t)

T
USER 163 > (defun test (n)
  (handler-case (fn-to-use n)
    (type-error () (format t "~%Type error~%") 0)))

TEST
USER 164 > (test #C(1 1))

Error: Undefined function: FN-TO-USE, with args
  (#C(1 1))

1 (continue) Call FN-TO-USE again
2 (abort) return to top loop level 0.

Type :c followed by a number to proceed
```

```

USER 165 : 1 > :b 10
Catch frame: (NIL)
Catch frame: #::|block-catcher-1854|
Call to *%UNDEFINED-FUNCTION-FUNCTION   :
Call to %EVAL   :
Call to RETURN-FROM   :
Call to %EVAL   :
Call to EVAL-AS-PROGN   :
Handler frame: ((TYPE-ERROR %LEXICAL-CLOSURE%
(LAMBDA
 (CONDITIONS::TEMP)
 (GO #:|lambda-633|))
((#:|lambda-632|) (N . #))
NIL ((#:|lambda-631|) (TEST)))
((#:|lambda-633| # #))))
Catch frame: "<* Catch All Object *>"
Call to LET   :

```

See also      **`set-debugger-options`**

## \*print-invisible-frames\* *Variable*

Summary      Controls whether invisible frames are printed in debugger output.

Package      **dbg**

Initial value      **nil**

Description      This variable is used by the debugger when it displays the stack frames.

Invisible frames are those for functions with **hcl:invisible-frame** declarations. These are normally not shown by the debugger. However if **\*print-invisible-frames\*** is true then these frames are displayed.

Notes      1. **\*print-invisible-frames\*** can be set to *value* by  
`(set-debugger-options :invisible value)`

2. **\*print-invisible-frames\*** is an extension to Common Lisp.

See also      **set-debugger-options**

**\*print-open-frames\***                                            *Variable*

Summary      Controls whether open frames are printed in debugger output.

Package      **dbg**

Initial value      **nil**

Description      This variable is used by the debugger when it displays the stack frames. Open frames are made by the system and are normally not shown by the debugger. However if **\*print-open-frames\*** is set to **t** then the open frames are displayed. It is unlikely that you need to examine open frames: their use is connected with implementation details.

Examples      **USER 52 > (setq dbg:\*print-open-frames\* t)**

**T**

**USER 53 > (car 2)**

**Error: Cannot take CAR of 2**

**1 (abort) return to top loop level 0.**

**Type :c followed by a number to proceed**

**USER 54 : 1 > :b 3**

**Open frame (5)**

**Open frame (5)**

**Call to CAR-FRAME :**

Notes      **\*print-open-frames\*** is an extension to Common Lisp.

|               | <b>*print-restart-frames*</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Variable |

## **remote-debugging-connection**

### **client-remote-debugging**

### **ide-remote-debugging**

### *System Classes*

Summary Classes of the connections in the remote debugging APIs.

Package `dbg`

Superclasses `t`

Description The system class `remote-debugging-connection` is a super-class of all the connection classes in the remote debugging APIs. `client-remote-debugging` and `ide-remote-debugging` are subclasses of `remote-debugging-connection`.

All client side connections are instances of `client-remote-debugging`, and all IDE side connections are instances of `ide-remote-debugging`.

You should not try to instantiate these classes or inherit from them. In typical use, you do not need to access instances of these classes.

See “Remote debugging” on page 25 for how to create and use remote debugging connections.

See also “Remote debugging” on page 25

## **remote-debugging-connection-add-close-cleanup**

## **remote-debugging-connection-remove-close-cleanup**

### *Functions*

Summary Add or remove a function that is called when a remote debugging connection is closed.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Arguments   | <p><code>connection</code> A <code>remote-debugging-connection</code>.</p> <p><code>function</code> A function designator or a list whose car is a function designator.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Values      | <code>changed-p</code> Boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | <p>The function <code>remote-debugging-connection-add-close-cleanup</code> records <code>function</code> as a cleanup in <code>connection</code>. When <code>connection</code> is closed, for whatever reason, each recorded <code>function</code> is invoked (by <code>funcall</code> for a <code>function</code> or <code>symbol</code>, or by applying the car to the cdr for a <code>list</code>). <code>function</code> is added only if it is not already in the list (tested by <code>equal</code>).</p> <p>The function <code>remote-debugging-connection-remove-close-cleanup</code> removes <code>function</code> from the cleanups if it was already added (tested by <code>equal</code>).</p> <p><code>changed-p</code> is <code>t</code> if the cleanups were modified and <code>nil</code> otherwise.</p> <p>Both functions may be called on either side (IDE or client).</p> |
| Notes       | <p>You should not assume anything about the order of calls to the cleanup functions.</p> <p>Unhandled errors during the call to <code>function</code> are handled and reported to the <code>log-stream</code> of the connection.</p> <p><code>remote-debugging-connection-remove-close-cleanup</code> is needed when you repeatedly create some objects that do not live for long but you still want cleanups for them. In this situation, the cleanup list would grow indefinitely unless you</p>                                                                                                                                                                                                                                                                                                                                                                                          |

call `remote-debugging-connection-remove-close-cleanup` when an object is discarded.

“Remote debugging” on page 25

## `remote-debugging-stream-peer-address` *Generic Function*

Summary Advanced: Return the peer address of a remote debugging stream.

Package `dbg`

Signature `remote-debugging-stream-peer-address stream => remote-host, remote-port`

Method signatures `remote-debugging-stream-peer-address (stream t)`  
`remote-debugging-stream-peer-address (stream socket-stream)`

Arguments `stream` A stream.

Values `remote-host` A string.

`remote-port` An integer.

Description The generic function `remote-debugging-stream-peer-address` returns the “peer address” of `stream` as two values:

`remote-host` The hostname of the remote host.

`remote-port` The port number on the remote host.

`remote-debugging-stream-peer-address` is called by `remote-debugging-connection-peer-address` with the stream that its `connection` uses to communicate with the other side. It is intended to allow you to implement remote debugging with other types of stream by calling `create-client-remote-debugging-connection` and `create-ide-remote-`

`debugging-connection`. In typical usage you do not need to define a method on `remote-debugging-stream-peer-address`.

The method specialized on `t` returns `nil` and `nil`.

The method specialized on `socket-stream` returns the peer hostname and port using `socket-stream-peer-address`.

`remote-debugging-stream-peer-address` may be called on either side (IDE or client).

## **remote-inspect** *Function*

**Summary** Client side: inspect a client side object in an Inspector tool on the IDE side.

**Package** `dbg`

**Signature** `remote-inspect object &key connection`

**Arguments** `object` Any object.

`connection` A `client-remote-debugging`.

**Description** The function `remote-inspect` causes an Inspector tool on the IDE side to inspect a client side object. The actual object in the Inspector is a remote object handle to the client side `object`. The Inspector tool itself is an ordinary Inspector tool, and there is nothing that makes it a “remote” tool in any way.

`connection` specifies which connection to use. If it is supplied and is a valid open client connection, it is used.

If `connection` is `nil` (the default) or is not a valid connection, `remote-inspect` first checks if there is a default connection

that is enabled (by default, if there is a default connection then it is enabled, see `set-remote-debugging-connection`) and uses that, the same as the Debugger and Listener do. However, if there is no default connection enabled, `remote-inspect` behaves differently from the Debugger and Listener, because there is no obvious time-point to close temporary connections.

If there is no enabled default connection, `remote-inspect` does the following:

- If a previous call to `remote-inspect` already opened a connection, then `remote-inspect` re-uses it.
- Otherwise, if there a default connection then `remote-inspect` uses it anyway (even though it is not enabled).
- Otherwise, if there is a remote debugging spec (configured either by `configure-remote-debugging-spec` or `with-remote-debugging-spec`), then `remote-inspect` tries to open a connection using that spec. If this works, it uses the new connection, and unless it is configured as the default (`setup-default` non-nil in `configure-remote-debugging-spec`) it also records it for future calls of `remote-inspect`.

#### Notes

With the default setting, the connection opening function (`start-client-remote-debugging-server` or `configure-remote-debugging-spec`) both configures and enables the default connection, so `remote-inspect` will just use that connection (maybe opening it the first time).

An ordinary inspector can inspect a remote object because the generic function `get-inspector-values` has a method that specializes on remote object handles to invoke `get-inspector-values` on the client side and return the results. Thus `remote-inspect` can work only if `get-inspector-values` works on the client side, which is not guaranteed when delivering an application at higher values of the `level` argument to `deliver`.

The only way to close a non-default connection that was opened by `remote-inspect` is to terminate the process that runs it on either the IDE or client side.

You can also inspect a remote object from the Remote Debugger or Remote Listener.

## `remote-object-p`

## `remote-object-connection`

### *Functions*

Summary      IDE side: Test for a remote object handle and return its connection.

Package      `dbg`

Signature      `remote-object-p object => boolean`  
`remote-object-connection remote-object => connection`

Arguments      `object`      Any object.

`remote-object`      A remote object handle.

Values      `boolean`      A boolean.

`connection`      An `ide-remote-debugging`.

Description      The function `remote-object-p` is a predicate, returning true if `object` is a remote object handle and false otherwise.

The function `remote-object-connection` returns the `ide-remote-debugging` that `remote-object` is associated with.

| Arguments   | <i>connection</i> A <code>client-remote-debugging</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <i>return-connection</i> The value of <i>connection</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description | <p>The function <code>set-default-remote-debugging-connection</code> sets <i>connection</i> as the default connection for the remote debugging interface on the client side (used when entering the debugger and by calls to <code>start-remote-listener</code> and <code>remote-inspect</code>).</p> <p>The default connection is used when the enabling switch is <code>t</code>, which it typically is because that is the default in <code>start-client-remote-debugging-server</code> and <code>configure-remote-debugging-spec</code>. The switch can also be set by <code>set-remote-debugging-connection</code> and in a dynamic scope by <code>with-remote-debugging-connection</code> and <code>with-remote-debugging-spec</code>.</p> <p>See <code>set-remote-debugging-connection</code> for a discussion about the enabling switch.</p> |

Notes In typical usage, you will not need to use `set-default-remote-debugging-connection`.

“Remote debugging” on page 25

## **set-remote-debugging-connection** *Function*

Summary Client side (advanced): Set the remote debugging connection to use on the client side.

Package `dbg`

Signature `set-remote-debugging-connection connection => res`

Arguments `connection`     `nil`, `t` or a `client-remote-debugging`.

Values `res`         The value of `connection` if it is valid.

Description The function `set-remote-debugging-connection` sets an enabling switch controlling which remote debugging connection will be used by the remote debugging interface (entering the debugger, `start-remote-listener` or `remote-inspect`) on the client side.

If `connection` is `t`, then the default connection will be used (which may be set by `set-default-remote-debugging-connection`, `start-client-remote-debugging-server`, or `configure-remote-debugging-spec`). If `connection` is an instance of `client-remote-debugging`, then `connection` itself will be used. If `connection` is `nil`, then no connection is specified (the API may open one when needed).

The setting is global, unless it is called within the dynamic extent of `with-remote-debugging-connection`, in which case its effects last until the exit from this extent.

When entering the debugger, the connection is used when `invoke-debugger` is called and no hook blocks it. Possible hooks include `*debugger-hook*` and `with-debugger-wrapper`. For the Remote Listener and Inspector, the functions `start-remote-listener` and `remote-inspect` use the connection.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p>In typical usage, you will not need to explicitly call <code>set-default-remote-debugging-connection</code>, because <code>start-client-remote-debugging-server</code> and <code>configure-remote-debugging-spec</code> (with the default parameters) both set the default connection.</p> <p>In all cases, if the debugger is invoked and there is no connection to use, LispWorks may open a connection if it was configured to do so by <code>configure-remote-debugging-spec</code> or <code>with-remote-debugging-spec</code>.</p> <p>You can obtain a client remote debugging connection by using the <code>:open-callback</code> keyword with <code>start-client-remote-debugging-server</code> or <code>configure-remote-debugging-spec</code>.</p> |

| Description | <p>The function <code>start-client-remote-debugging-server</code> starts a client side server for remote debugging, which will create a client side remote debugging connection when a remote machine connects to it. With the default settings, this remote debugging connection will become the default connection and will be enabled for re-use whenever a connection is needed (entering the debugger, or calls to <code>start-remote-listener</code> or <code>remote-inspect</code>).</p> <p>The main operation of <code>start-client-remote-debugging-server</code> is calling <code>start-up-server</code> with <i>port</i> and a function that calls <code>create-client-remote-debugging-connection</code> to create a client for every connection to the server. <i>port</i> defaults to the value of <code>*default-client-remote-debugging-server-port*</code>, which is 21102 initially.</p> <p>The other keyword arguments affect what else <code>start-client-remote-debugging-server</code> does.</p> <p>If <i>open-callback</i> is non-<code>nil</code>, it is called with the each new connection that is created. <i>open-callback</i> defaults to <code>nil</code>.</p> <p>If <i>setup-default</i> is non-<code>nil</code> (the default when <i>open-callback</i> is <code>nil</code>), every new connection is made the default connection by a call to <code>set-default-remote-debugging-connection</code>, and if <i>enable</i> is non-<code>nil</code> (the default), it will be enabled for re-</p> |                                                                 |

use by `set-remote-debugging-connection` with argument `t`. If `setup-default` is `nil` (the default when `open-callback` is non-nil) then `enable` is ignored. `setup-default` defaults to `(not open-callback)`.

If `log-stream` is non-nil, LispWorks writes error messages to it relating to failures during communication on a connection. These failures should not happen normally, but may happen if something writes to the remote debugging connection not through the remote debugging interface. `log-stream` defaults to `nil`.

`start-client-remote-debugging-server` returns `process`, which is the result of `start-up-server`. You can use `server-terminate` to stop it.

#### Notes

To have a connection, the IDE side needs to connect to the client hostname on port number `port` using `ide-connect-remote-debugging`, or code that does similar things.

In normal operation, it is assumed that the IDE side will connect once, and from that point onward this connection will be used for all remote debugging. If the IDE subsequently opens another connection without first closing the first connection, then the first connection will "leak" on the client side. It is the responsibility of the IDE to close it in this case.

`open-callback` allows more complex usage, for example to store the connection somewhere and use it when required by `with-remote-debugging-connection` or `set-remote-debugging-connection`. Note that `setup-default` is `nil` by default when `open-callback` is non-nil.

`start-client-remote-debugging-server` is implemented using the other functions discussed in this section, so you can reasonably easily write your own version of it if you need to.

| <code>socket-filter</code> | A function of one argument or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                   |                       |                            |                                                  |                   |           |                         |                                        |
| <code>name</code>          | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                   |                       |                            |                                                  |                   |           |                         |                                        |
| <code>log-stream</code>    | An output stream or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                   |                       |                            |                                                  |                   |           |                         |                                        |
| Values                     | <code>server-process</code> A process handling incoming connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                   |                       |                            |                                                  |                   |           |                         |                                        |
| Description                | <p>The function <code>start-ide-remote-debugging-server</code> starts a TCP server (by calling <code>start-up-server</code>) that creates IDE remote debugging connections.</p> <p><code>port</code> must be an integer port number or string service name. It is supplied as the <code>service</code> argument to <code>start-up-server</code>. <code>port</code> defaults to the value of <code>*default-ide-remote-debugging-server-port*</code>, which is 21101 initially.</p> <p><code>name</code> is used in the name of the created connections.</p> <p>If <code>log-stream</code> is non-nil, LispWorks writes error messages to it relating to failures during communication on a connection. These failures should not happen normally, but may happen if something writes to the remote debugging connection not</p> |                   |                       |                            |                                                  |                   |           |                         |                                        |

through the remote debugging interface. *log-stream* defaults to `nil`.

If *socket-filter* is non-`nil`, it is called with the connected socket before creating the connection, and if it returns `nil` then the socket is closed and no connection is created. *socket-filter* defaults to `nil`.

The server creates IDE remote debugging connections by calling `create-ide-remote-debugging-connection` with the connected socket, a name (constructed from *name*, the peer address of the socket and a counter) and *log-stream*.

`start-ide-remote-debugging-server` returns *server-process*, which is the first result of `start-up-server`. You can terminate the server by calling `server-terminate` with *server-process*.

#### Notes

The client would normally open a connection using `configure-remote-debugging-spec` with host specifying the machine on which `start-ide-remote-debugging-server` has been called with the same port as *port* (which defaults to the value of `*default-ide-remote-debugging-server-port*` for both functions).

The underlying TCP stream functionality must be working between the machines, that is they must be able to connect by TCP.

When using the Remote Debugger, Remote Listener or Inspector, you do not need to access the connection directly because the tools do it for you. In addition, `create-ide-remote-debugging-connection` remembers the connection, so all the IDE side functions that look for connections will find it.

*socket-filter* can call `get-socket-peer-address` to check who is connecting. It can also be used just to log that a connection has been made, but must return `t` in this case.

You could easily implement your own version of `start-ide-remote-debugging-server` if needed using `start-up-server` and `create-ide-remote-debugging-connection`.

| Description | <p>The function <code>start-remote-listener</code> starts a Remote Listener tool on the IDE side, such that reading and evaluation is done on the client side where the <code>start-remote-listener</code> was called.</p> <p><code>start-remote-listener</code> first tells the IDE to start the Listener, and then runs a read-eval-print loop that communicates with the IDE's Listener over the connection.</p> <p>If <code>new-process-p</code> is non-<code>nil</code> (the default), then a new Lisp process is created to start the Listener and run the read-eval-print loop. This process runs until the read-eval-print loop</p> |                                                              |

exits. If *new-process-p* is `nil`, then the read-eval-print loop runs in the current process and `start-remote-listener` does not return until the read-eval-print loop exits.

*message*, when is not `nil`, is printed into the Listener tool before the first prompt appears.

*connection* (default `nil`) controls which connection to use. If *connection* is non-`nil` and is connected then it is used. Otherwise `start-remote-listener` uses the same mechanism as the debugger to find the connection, which by default means re-using an existing connection if one exists, or opening a new one (under the control of the remote debugging spec). In typical usage, this be set up by either `configure-remote-debugging-spec` or `start-client-remote-debugging-server`. See “Simple usage” on page 26 and “Advanced usage - multiple connections” on page 33 for details.

*close-on-exit* is used only when *connection* is non-`nil`. When *close-on-exit* is non-`nil`, the connection is closed when the read-eval-print loop exits. Otherwise (the default), the connection remains open for later re-use.

If the Listener tool on the IDE side is closed, then the read-eval-print loop exits. Normally this is the only way that the loop exits, but you could also exit it by throwing to a surrounding catch (when *new-process-p* is `nil`) or by terminating the process (by `current-process-kill`).

`start-remote-listener` returns `nil` if *connection* is not a valid connection (either `nil` or already closed) and it cannot find the connection to use. Otherwise, if *new-process-p* is non-`nil` (the default) it returns `t` immediately, and if *new-process-p* is `nil` it returns `nil` only when the Listener is closed.

## Notes

Using *message* is an easy way for the client to write some text to the IDE even when you do not need a Listener.

| Summary       | Controls blocking of multiprocessing in the terminal debugger.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Package       | <b>dbg</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Initial value | <b>t</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description   | <p>When the debugger is entered on the terminal, multiprocessing is blocked if the value of <b>*terminal-debugger-block-multiprocessing*</b> is <b>t</b>. This is the default value.</p> <p>If you set this variable to <b>nil</b> then other processes, including timers, will continue to run in parallel to the process that entered the terminal debugger (as they did before the debugger was entered). Beware that this will make it more difficult to debug multi-process activities.</p> <p>The other allowed value is <b>:maybe</b>. This means that multiprocessing is blocked in the terminal debugger unless the debugger was entered from the CAPI environment.</p> <p>The value of <b>*terminal-debugger-block-multiprocessing*</b> affects the behavior of a REPL started by <b>start-tty-listener</b>.</p> |
| Example       | <p>This listener session illustrates the effect of <b>*terminal-debugger-block-multiprocessing*</b>.</p> <p>Firstly we see the default behavior whereby a call to <b>print</b> in another process is blocked by the debugger.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

```
CL-USER 1 > dbg:*terminal-debugger-block-
multiprocessing*
T

CL-USER 2 > unbound

Error: The variable UNBOUND is unbound.
 1 (continue) Try evaluating UNBOUND again.
 2 Specify a value to use this time instead of
evaluating UNBOUND.
 3 Specify a value to set UNBOUND to.
 4 (abort) Return to level 0.
 5 Return to top-level loop.
 6 Return from multiprocessing.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 3 : 1 > (setq *timer* (mp:make-timer 'print
10))
Warning: Setting unbound variable *TIMER*
#<Time Event : PRINT>

CL-USER 4 : 1 > (mp:schedule-timer-relative *timer* 1)
#<Time Event : PRINT>

CL-USER 5 : 1 > :a
```

On leaving the debugger the output 10 from the call to `print` appears. Then we set `*terminal-debugger-block-multiprocessing*` to `nil` and repeat the commands:

```

CL-USER 6 >
10
(setf dbg:*terminal-debugger-block-multiprocessing*
nil)
NIL

CL-USER 7 > unbound

Error: The variable UNBOUND is unbound.
 1 (continue) Try evaluating UNBOUND again.
 2 Specify a value to use this time instead of
evaluating UNBOUND.
 3 Specify a value to set UNBOUND to.
 4 (abort) Return to level 0.
 5 Return to top-level loop.
 6 Return from multiprocessing.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 8 : 1 > (setq *timer* (mp:make-timer 'print
10))
#<Time Event : PRINT>

CL-USER 9 : 1 > (mp:schedule-timer-relative *timer* 1)
#<Time Event : PRINT>

CL-USER 10 : 1 >
10

```

Notice above that the output 10 from the call to `print` appears after 1 second, in the debugger. Multiprocessing was not blocked.

| Signature   | <code>with-debugger-wrapper wrapper &amp;body body =&gt; results</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |
| Arguments   | <code>wrapper</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | A function designator.         |
|             | <code>body</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Forms.                         |
| Values      | <code>results</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Results of <code>body</code> . |
| Description | <p>The macro <code>with-debugger-wrapper</code> executes forms in <code>body</code> with the function <code>wrapper</code> bound as a "debugger wrapper". This debugger wrapper takes effect only if the code in <code>body</code> tries to invoke the debugger (by a call to <code>invoke-debugger</code>), typically indirectly as a result of an error. Instead of entering the debugger, the debugger wrapper is called with two arguments: a function to call to enter the debugger, and the condition. The wrapper can do whatever is needed. If it wants to enter the debugger, it does it by calling its first argument with the second argument:</p> <pre>(funcall function condition)</pre> |                                |
| Example     | <p>Suppose that you run many processes in parallel with the same code. If the code is broken then every process will get an error. This example shows how a debugger wrapper can be used to keep a <code>lock</code> around entry to the debugger, so that the processes enter the debugger one by one. It contains firstly the "application code", then the debugger wrapper, and lastly forms which execute the application with or without the debugger wrapper.</p>                                                                                                                                                                                                                               |                                |

```

| Values      | <i>body-values</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | The values returned by <i>body</i> .                                          |
| Description | The macro <code>with-remote-debugging-connection</code> dynamically binds an enabling switch controlling which remote debugging connection will be used by the remote debugging interface (entering the debugger, <code>start-remote-listener</code> , <code>remote-inspect</code> ) on the client side while evaluating the forms in <i>body</i> as an implicit <code>progn</code> .<br><br>See <code>set-remote-debugging-connection</code> for details of how <i>connection</i> is interpreted.<br><br>Inside the dynamic extent of <i>body</i> , calls to <code>set-remote-debugging-connection</code> affect the switch only until the end of the <code>with-remote-debugging-connection</code> form. |                                                                               |
| Notes       | In typical usage, you will not need to use <code>with-remote-debugging-connection</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                               |
| See also    | <code>set-remote-debugging-connection</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                               |

## with-remote-debugging-spec Macro

|             | <code>body</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Lisp forms.                                                                        |
| Values      | <code>body-values</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | The values returned by <code>body</code> .                                         |
| Description | <p>The macro <code>with-remote-debugging-spec</code> establishes a dynamic extent of connection specification, calls <code>configure-remote-debugging-spec</code> passing it <code>host</code>, any supplied keywords (<code>port</code>, <code>log-stream</code>, <code>failure-function</code>, <code>timeout</code>, <code>open-callback</code>) and also <code>:setup-default nil :enable nil</code>. <code>body</code> is evaluated as an implicit <code>progn</code> in this dynamic extent. On exiting <code>with-remote-debugging-spec</code>, the connection specification reverts to what it was on entry.</p> <p>The effect is to have a configured connection specification in the dynamic extent of <code>body</code> that is different from the global one, without having any effect on the global settings.</p> |                                                                                    |

**with-remote-debugging-spec** returns the values returned by *body*.

See **configure-remote-debugging-spec** for the meaning of *host* and the other keywords.

## The DSPEC Package

This chapter describes symbols available in the `DSPEC` package.

The `dspec` system is discussed in detail in Chapter 7, “Dspecs: Tools for Handling Definitions”.

| <b>*active-finders*</b> |                                                                                                                                                                                                                                                                                                                          | <i>Variable</i> |

| Summary                 | Controls how source finding operates.                                                                                                                                                                                                                                                                                    |                 |
| Package                 | <code>dspec</code>                                                                                                                                                                                                                                                                                                       |                 |
| Initial value           | <code>(:internal)</code>                                                                                                                                                                                                                                                                                                 |                 |
| Description             | The variable <code>*active-finders*</code> controls how the functions <code>find-name-locations</code> and <code>find-dspec-locations</code> operate. This in turn controls source the finding commands in the LispWorks IDE. You can switch between different sources of location information by setting this variable. |                 |
|                         | The legal values for the elements of <code>*active-finders*</code> are:                                                                                                                                                                                                                                                  |                 |

|                                                                                                                                                                                                                                                                                       |                                                                                                                                                         |

| <i>dspec</i> | A dspec.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |          |             |                                                     |
| <i>body</i>  | Lisp forms, evaluated as an implicit <b>progn</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |              |          |             |                                                     |
| Values       | <i>result</i> The result of <i>body</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |              |          |             |                                                     |
| Description  | <p>The macro <b>def</b> informs the system that any definitions within <i>body</i> should be recorded as being within the dspec <i>dspec</i>. This means that when something attempts to locate such a definition, it should look for a definition named <i>dspec</i>.</p> <p>Use <b>def</b> to wrap a group of definitions so that source location for one of the group causes the LispWorks Editor to look for the dspec in the <b>def</b> instead. Typically you will also need a <b>define-form-parser</b> definition for the macro that expands into the <b>def</b>.</p> <p><i>dspec</i> can be non-canonical.</p> <p>You can also use <b>def</b> to provide a dspec for a definition that has its own class that has been defined with <b>define-dspec-</b></p> |              |          |             |                                                     |

`class`. In this case, you arrange to call `record-definition` with the same dspec as in the example below.

It is also possible to mix these cases, recording a dspec and also grouping inner definitions. For example `defstruct` does this, recording itself and also grouping definitions such as the constructor function.

In all cases, to make source location work in the LispWorks editor you typically also need a `define-form-parser` definition for the macro that expands into the `def`.

Example

```
(defmacro define-wibble (x y)
  `(~(dspec:def (define-wibble ,x)
    (set-wibble-definition ',x ',y (dspec:location)))))

(defun set-wibble-definition (x y loc)
  (when (record-definition `(define-wibble ,x) loc)
    ;; defining code here
    ))
```

`location`

## define-dspec-alias

*Macro*

Summary

Informs the dspec system that a definer expands into another definer.

Package

`dspec`

Signature

`define-dspec-alias name lambda-list &body body`

Arguments

*name*      A symbol naming a definer.

*lambda-list*      A list representing the parameters of a *name* dspec.

*body*      Forms evaluated to yield a dspec.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <code>define-dspec-alias</code> works rather like <code>deftype</code>. Dspecs whose <code>car</code> is <i>name</i> should have parameters that match <i>lambda-list</i>. They will be canonicalized into the dspec returned by <i>body</i>.</p> <p><code>define-dspec-alias</code> is useful when you add a new way of making existing definitions with a new defining form that expands into a system-provided defining form. The dspec system should consider the new and system-provided definers as variant forms of the same dspec class. <code>define-dspec-alias</code> is used to convert one of them to the other during canonicalization by <code>canonicalize-dspec</code>.</p> |
| Example     | <code>defparameter</code> is pre-defined as an alias for <code>defvar</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| See also    | <code>canonicalize-dspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>prettyf</i>         | A function to return a prettier form of a dspec of the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>definedp</i>        | A function to decide if a dspec of the class currently has a definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>object-dspec</i>    | A function to return the dspec from an object if it was defined by the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>defined-parts</i>   | A function to return all the currently defined parts in the class for a given a primary-name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>aggregate-class</i> | The aggregate dspec class for a part dspec.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description            | <p>The macro <code>define-dspec-class</code> defines a dspec class, providing handlers for definitions in that dspec class.</p> <p><code>define-dspec-class</code> defines <i>name</i> as a dspec class, inheriting from the dspec class <i>superspace</i>. <i>superspace</i> should be <code>nil</code> to define a new top-level dspec class.</p> <p><i>documentation</i> should be a string documenting the dspec class. For example "<code>My Objects</code>".</p> <p>After evaluating a <code>define-dspec-class</code> form, <i>name</i> can be used by defining forms to record locations of definitions of that dspec class name by calling <code>record-definition</code>.</p> <p>All of the remaining arguments described below can be omitted if not needed. The most important arguments for the LispWorks IDE are <i>definedp</i> and <i>undefiner</i>.</p> <p>If <i>undefiner</i> is supplied, its value must be a function of one argument. When LispWorks wants to remove a definition, it will call the function with a canonical dspec of class <i>name</i>. The function should return a form that removes the current definition of that dspec. For example, the undefining form for package dspecs might be <code>delete-package</code>. If <i>undefiner</i> is omitted, then definitions of this class cannot be undefined.</p> <p>If <i>canonicalize</i> is supplied, its value must be a function of one argument. The function will be called by <code>canonicalize-</code></p> |

`dspec` for a dspec of the given class. The value returned by the canonicalize function must be a fully canonical dspec of the given class. A typical use for the canonicalize function would be to remove extra options from the dspec which are not required to make the dspec unique. The canonicalize function should return `nil` for malformed dspecs and should take care not to signal an error. The default canonicalize function returns the dspec if it has the form

`(name symbol)`

If `prettify` is supplied, its value must be a function of one argument. When LispWorks wants to print a dspec, for example in an error message, it will call the prettify function for the class of the dspec. The argument will be the canonical dspec and the function should return a dspec which is considered "prettier" for a user to see. The default prettify function returns the dspec unchanged.

If `definedp` is supplied, its value must be function of one argument. When LispWorks wants to discover if a given dspec is defined, it calls the function with the `dspec-primary-name` of the dspec. The `definedp` function should return true if the primary name is defined in this dspec class and `nil` otherwise. The default `definedp` function always returns `nil`.

If `object-dspec` is supplied, its value must be a function of one argument. When LispWorks wants to find the dspec that created a given object (for example a package object created by a `defpackage` form), it calls the `object-dspec` functions in all dspec classes. The function should return a dspec for the object if that object was defined by the dspec class or `nil` otherwise. For example, the `object-dspec` function for package dspecs might be:

```
#'(lambda (obj)
  (and (packagep obj)
       `(package ,(package-name obj))))
```

The *object-dspec* function is used by the menu command **Find Source** in the LispWorks IDE Inspector tool to find where the current object was defined.

If *defined-parts* is supplied, its value must be a function of one argument. When LispWorks wants to find all the definitions that are parts of a given aggregate dspec class, it calls the *defined-parts* functions with the **dspec-primary-name** of the dspec in each class that aggregates with it. The function should return a list of dspecs which are defined parts of the primary name in the class *name*. If *defined-parts* is supplied, *aggregate-class* must also be supplied.

If *aggregate-class* is supplied and non-nil, its value must be a symbol naming a dspec class that is the aggregate class of the parts defined by *name* dspecs. For example, the aggregate class of **method** is **defgeneric** because methods are the defined parts of a particular generic function. If *aggregate-class* is supplied, the *defined-parts* must also be supplied. If *aggregate-class* is nil then *name* is not a part class.

To make **c1:documentation** work for your dspec class, add a suitable method as described for **documentation**.

Example See “Dspec classes” on page 77.

| Arguments         | <p><i>definer-and-options</i></p> <p>A symbol <i>definer</i> naming a definer of functions, macros, variables and so on, or a list (<i>definer options</i>) where <i>options</i> is a plist of keys and values.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>parameters</i> | <code>nil</code> , or list of parameters <i>params</i> in the top level form, optionally ending with <code>&amp;rest param-getter</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>body</i>       | The body of a parser function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values            | <i>parser</i> A form parser function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description       | <p>The macro <code>define-form-parser</code> defines a form parser for forms beginning with <i>definer</i>.</p> <p><i>options</i> is a property list with the following keys allowed:</p> <ul style="list-style-type: none"> <li><code>:parser</code> A parser function <i>parser-function</i>.</li> <li><code>:alias</code> A dspec class or alias <i>alias</i>.</li> <li><code>:anonymous</code> A boolean.</li> </ul> <p>The parser function defined is named by <i>parser-function</i>. If the <code>:parser</code> option is omitted then the name defaults to a symbol in the current package whose symbol name is the symbol name of <i>definer</i> with "<code>-FORM-PARSER</code>" appended.</p> <p>If <i>parameters</i> and <i>body</i> are given, then <i>parser-function</i> is defined as a global function that is expected to return a dspec for the defining form or <code>nil</code> if this is not possible. Within <i>body</i>, <i>definer</i> is bound to the <code>car</code> of the actual form being parsed. In simple cases, this is just <i>definer</i>, but if the form parser is used as in the <code>:alias</code> option of another form parser then the symbol will be bound to the <code>car</code> of that form instead.</p> |

The *params* are bound to subsequent subforms of the defining form. If `&rest param-getter` is supplied, then it is bound to a function of no arguments that returns two values: the next subform if there is one and a boolean to indicate if a subform was found.

If *parameters* and *body* are omitted, then *parser-function* is expected to be a form parser defined by a different `define-form-parser` form, or you can specify as an alias a definer with an existing form parser via the value *alias* of the `:alias` key in *options*.

If the `:anonymous` option is non-nil then *definer* is not associated with the form parser. This is useful in conjunction with *parameters* and *body* for defining generic form parsers that can be used in other `define-form-parser` forms.

LispWorks contains pre-defined form parser functions for the Common Lisp definers `defun`, `defmethod`, `defgeneric`, `defvar`, `defparameter`, `defconstant`, `defstruct`, `defclass`, `defmacro` and `deftype` and for LispWorks definers such as `fli:define-foreign-type` and `dspec:define-form-parser` itself.

When a defining symbol *definer* has an associated form parser, this parser function is used by the source location commands such as **Expression > Find Source** in the LispWorks IDE. Having identified the file where the definition was recorded, LispWorks parses the top level forms in the file looking for the one which matches the definition spec. When found, this match is displayed.

**Example** Define a parser for `def-foo` forms which have a single name as the second element in the form:

```
(dspec:define-form-parser def-foo (name)
  `(&,def-foo ,name))
```

Define a parser for `def-other-foo` forms which are like `def-foo` forms:

```
(dspec:define-form-parser
  (def-other-foo (:parser def-foo-form-parser)))
```

Define a parser for **def-bar** forms whose name is made from the second element of the form and any subsequent keywords:

```
(dspec:define-form-parser def-bar (name &rest details)
  `(~(,def-bar ,name
    ,(loop for detail = (funcall details)
           while (keywordp detail)
           collect detail))))
```

Define a parser for forms which have another name as the second element in the form:

```
(dspec:define-form-parser (two-names
  (:anonymous t)) (name1 name2)
  `(~(,two-names ,name1 ,name2)))
```

Define a new way to define CLOS methods, and tell the dspec system to treat them the same. Note the use of **define-dspec-alias** to inform the dspec system that **my-defmethod** is another way of naming **defmethod** dspecs:

```
(defmacro my-defmethod (name args &body body)
  `(~(defmethod ,name ,args
    ,@body))

(dspec:define-dspec-alias my-defmethod
  (name &rest args)
  `(~(defmethod ,name ,@args)))

(my-defmethod foo ((x number))
  42)

(dspec:define-form-parser
  (my-defmethod
    (:parser
      #.(dspec:get-form-parser 'defmethod))))
```

A simpler way to write the last form is:

```
(dspec:define-form-parser
  (my-defmethod
    (:alias defmethod)))
```

## discard-source-info

*Function*

Summary      Clears the internal dspec database.

Package      **dspec**

Signature      **discard-source-info => nil**

Arguments      None.

Values      Returns **nil**.

Description      The function **discard-source-info** removes all source location information from the internal dspec database.

Example      To build **my-image** which does not contain source locations for the definitions loaded, but retaining a tags database of those definitions:

```
(load-all-patches)
(load "my-code")
(dsdp:save-tags-database
  (compile-file-pathname #P"my-tags-database"))
(dsdp:discard-source-info)
(save-image "my-image")
```

See also      **save-tags-database**

## dspec-class

*Function*

Summary      Returns the dspec class of a dspec.

Package      **dspec**

|             |                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>dspec-class dspec =&gt; class</code>                                                                                                                                           |
| Arguments   | <code>dspec</code> A dspec.                                                                                                                                                          |
| Values      | <code>class</code> A dspec class name.                                                                                                                                               |
| Description | The function <code>dspec-class</code> returns the dspec class name for <code>dspec</code> .                                                                                          |
| Example     | <pre>CL-USER 14 &gt; dspec:dspec-class 'foo FUNCTION  CL-USER 15 &gt; dspec:dspec-class '(defmacro foo) DEFMACRO  CL-USER 16 &gt; dspec:dspec-class '(defmethod foo) DEFMETHOD</pre> |

| Arguments   | <i>dspec</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A dspec.                                            |
| Values      | <i>locations</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A list of pairs ( <i>recorded-dspec location</i> ). |
| Description | <p>The function <b>dspec-definition-locations</b> returns the locations of the definitions recorded for the dspec <i>dspec</i>.</p> <p>For each known definition <i>recorded-dspec</i> names the definition that defined <i>dspec</i> in <i>location</i>, and <i>location</i> is a pathname or keyword as described in <b>at-location</b>.</p> <p>Note that non-file locations, such as <code>:unknown</code>, can occur in the list. The locations in <i>locations</i> are all basic locations: that is, there are no <code>(:inside ...)</code> locations.</p> |                                                     |

If *dspec* is a local dspec, the parent function is located.

Example      `CL-USER 6 > (dspec:dspec-definition-locations  
                  '(defun foo-bar))  
      (((DEFSTRUCT FOO) #P"C:/temp/hack.lisp"))`

See also      `name-definition-locations`

## **dspec-equal** *Function*

Summary      Tests two dspecs for equality as dspecs.

Package      `dspec`

Signature      `dspec-equal dspec1 dspec2 => result`

Arguments      `dspec1, dspec2`    Dspecs.

Values      `result`            A boolean.

Description      The function `dspec-equal` compares *dspec1* and *dspec2* for equality as dspecs.

Both arguments are canonicalized before the comparison.

Dspecs in different subclasses of the same namespace are `dspec-equal` if their names match.

Unknown dspecs are compared simply by `equal`.

Example      `CL-USER 44 > (dspec:dspec-equal '(deftype foo)  
                  '(defclass foo))`  
                  T

## **dspec-name** *Function*

Summary      Extracts the name from a canonical dspec.

|             |                                                                                                                                                                                                                                                                                    |                    |

| Arguments   | <i>classes</i>   | A list of dspec class names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | <i>name</i>      | A name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Values      | <i>locations</i> | A list of pairs ( <i>recorded-dspec location</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description |                  | <p>The function <code>find-name-locations</code> returns the locations of the relevant definitions for <i>name</i> in the classes listed in <i>classes</i>.</p> <p>For each known definition <i>recorded-dspec</i> names the definition that defined <i>name</i> in <i>location</i>, and <i>location</i> is a pathname or keyword as described in <code>at-location</code>.</p> <p>The location information is collected from all finders on <code>*active-finders*</code>, that is, the relevant definitions are those known to at least one of these finders.</p> <p>If two or more finders return the same pair (<i>recorded-dspec location</i>), as compared by <code>dspec-equal</code> and location equality, then only the first occurrence of the pair (in the order of <code>*active-finders*</code>) appears in <i>locations</i>.</p> |

| get-form-parser |                | <i>Function</i>                                    |
|-----------------|----------------|----------------------------------------------------|
| Summary         |                | Returns the form parser associated with a definer. |
| Package         |                | <code>dspec</code>                                 |
| Signature       |                | <code>get-form-parser definer =&gt; parser</code>  |
| Arguments       | <i>definer</i> | A symbol naming a definer.                         |
| Values          | <i>parser</i>  | A form parser function, or <code>nil</code> .      |

|             |                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>get-form-parser</code> returns a form parser function if there is one associated with <code>definer</code>.</p> <p>This is the case for predefined definers and for those for which you have established a form parser using <code>define-form-parser</code>.</p> <p>If there is no associated form parser, <code>nil</code> is returned.</p> |
| Example     | <pre>CL-USER 1 &gt; dspec:get-form-parser 'defun DSPEC:NAME-ONLY-FORM-PARSER</pre>                                                                                                                                                                                                                                                                                  |

|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary         | Returns the source location.                                                                                                                                                                                                                                                                                                        |
| Package         | <code>dspec</code>                                                                                                                                                                                                                                                                                                                  |
| Signature       | <code>location =&gt; location</code>                                                                                                                                                                                                                                                                                                |
| Values          | <code>location</code> A pathname or a keyword.                                                                                                                                                                                                                                                                                      |
| Description     | The macro <code>location</code> returns a location suitable for passing to <code>record-definition</code> . This is usually done via a separate defining function. You will need to use <code>location</code> only if you create your own ways of making definitions (and not if your definers call only system-provided definers). |
| Example         | <pre>(defmacro define-wibble (x y)   `(dspec:def (define-wibble ,x)     (set-wibble-definition ',x ',y (dspec:location)))))  (defun set-wibble-definition (x y loc)   (when (record-definition `(define-wibble ,x) loc)     ;; defining code here   ))</pre>                                                                        |
| See also        | <code>at-location</code><br><code>def</code><br><code>record-definition</code>                                                                                                                                                                                                                                                      |

| <b>name-defined-dspecs</b> | <i>Function</i>                                            |
|----------------------------|------------------------------------------------------------|
| Summary                    | Returns defined dspecs matching a name.                    |
| Package                    | <code>dspec</code>                                         |
| Signature                  | <code>name-defined-dspecs classes name =&gt; dspecs</code> |
| Arguments                  | <code>classes</code> A list of dspec class names.          |

|             |               |                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>name</i>   | A name.                                                                                                                                                                                                                                                                 |
| Values      | <i>dspecs</i> | A list of canonical dspecs.                                                                                                                                                                                                                                             |
| Description |               | <p>The function <code>name-defined-dspecs</code> looks in each of the dspec classes <i>classes</i> for definitions of <i>name</i>.</p> <p>For each definition found (as if by <code>dspec-defined-p</code>), the result <i>dspecs</i> contains the canonical dspec.</p> |
| See also    |               | <code>dspec-defined-p</code>                                                                                                                                                                                                                                            |

## **name-definition-locations** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                      |                                                     |

## **name-only-form-parser** *Function*

Summary     A pre-defined form parser.

Package     [dspec](#)

Signature    **name-only-form-parser** *top-level-form* *getter* => *dspec*

Arguments    *top-level-form*    A top level defining form.

*getter*        The subform getter function.

Values       *dspec*        A dspec.

Description    The function **name-only-form-parser** is a predefined form parser for use with **define-form-parser**. The parser consumes one subform and returns it.

**name-only-form-parser** can be used for function definitions where the function name is an abbreviation for the full dspec. It is the predefined parser for **defun**, **defmacro** and **defgeneric** forms.

You can define it to be the parser for your defining forms. using **define-form-parser**.

Example      (defmacro my-definer (name &body body)  
                  `(defun ,name (x)  
                  ,@body))

```
(dspec:define-form-parser
  (my-definer (:parser
    dspec:name-only-form-parser)))
```

| Values       | <code>dspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A dspec or <code>nil</code> . |
| Description  | <p>The function <code>object-dspec</code> returns a dspec for <i>object</i> if there is one, or <code>nil</code> otherwise. When the result <code>dspec</code> is not <code>nil</code>, it is a dspec as described in “Forms of dspecs” on page 76.</p> <p>An object has a dspec only when it represents the result of some definition. The most useful cases are functions (of any kind) and methods, because their dspecs can be used to trace and advise them. Classes and packages also have dspecs.</p> <p>Dspecs can also be useful for finding where the definition of the object originated, either by using dspec functions like <code>find-dspec-locations</code>, which returns the location, or using the editor command <code>Find Source For Dspec</code>, which edits them. The Common Lisp function <code>ed</code> also recognizes dspecs and goes to the source.</p> <p>If <i>object</i> does not have a dspec then <code>object-dspec</code> returns <code>nil</code>.</p> |                               |

## parse-form-dspec

*Function*

|             |                                                                                                                                   |                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| Summary     | Parses the dspec from a defining form.                                                                                            |                               |
| Package     | <code>dspec</code>                                                                                                                |                               |
| Signature   | <code>parse-form-dspec form =&gt; result</code>                                                                                   |                               |
| Arguments   | <code>form</code>                                                                                                                 | A form.                       |
| Values      | <code>result</code>                                                                                                               | A dspec or <code>nil</code> . |
| Description | The function <code>parse-form-dspec</code> invokes the defined form parser for <code>form</code> and returns the resulting dspec. |                               |
| Example     | <pre>(parse-form-dspec '(def-foo my-foo (arg) (foo-it arg))) =&gt; (def-foo my-foo)</pre>                                         |                               |
| See also    | <code>define-form-parser</code><br><code>get-form-parser</code>                                                                   |                               |

## record-definition

*Function*

|           |                                                                                          |                        |
|-----------|------------------------------------------------------------------------------------------|------------------------|
| Summary   | Checks for existing definitions and records a new definition.                            |                        |
| Package   | <code>dspec</code>                                                                       |                        |
| Signature | <code>record-definition dspec location &amp;key check-redefinition-p =&gt; result</code> |                        |
| Arguments | <code>dspec</code>                                                                       | A dspec.               |
|           | <code>location</code>                                                                    | A pathname or keyword. |
|           | <code>check-redefinition-p</code>                                                        | A boolean.             |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Values              | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A generalized boolean. |
| Description         | <p>The function <b>record-definition</b> tells the system that <i>dspec</i> is defined at <i>location</i>.</p> <p>The system-provided definer macros call the function <b>record-definition</b> with the current location.</p> <p><i>location</i> should be a pathname or keyword as returned by <b>location</b>.</p> <p>When <i>check-redefinition-p</i> is true, it checks for existing definitions and reports these according to the value of <b>*redefinition-action*</b>. The default value of <i>check-redefinition-p</i> is <i>t</i>.</p> <p>If the definition is made, then <i>result</i> is true. If the definition is not made then <i>result</i> is <i>nil</i>. This can happen if you choose the "Don't redefine ..." restart at a redefinition error.</p> |                        |
| Notes               | You should not usually call <b>record-definition</b> , since all the system-provided definers call it. However, for new classes of definition which you add with <b>define-dspec-class</b> , you should call <b>record-definition</b> for dspecs in their new classes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                        |
| Compatibility notes | <b>record-definition</b> was documented in the <b>lispworks</b> package in LispWorks 4.3 and earlier. Although it is currently still available there, this may change in future releases and you should now reference it via the <b>dspec</b> package.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                        |

## **\*redefinition-action\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Specifies the action on some redefinitions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Package       | <code>dspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Initial value | <code>:warn</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description   | <code>*redefinition-action*</code> controls messages about redefinitions seen by the source location system.<br><br>If <code>*redefinition-action*</code> is set to <code>:warn</code> then you are warned. If it is set to <code>:quiet</code> or <code>nil</code> , the redefinition is done quietly. If, however, it is set to <code>:error</code> , then LispWorks signals an error.<br><br>These messages are triggered by defining forms provided, but they could also be from any call to <code>record-definition</code> . |
| Notes         | <code>*redefinition-action*</code> does not affect the behavior of <code>cl:defstruct</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                     |                                                                                                                                                                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility notes | <code>*redefinition-action*</code> is documented in the <code>lispworks</code> package in LispWorks 4.3 and earlier. It is still currently still available there but this may change in future releases and you should now reference it via the <code>dspec</code> package. |

| Values               | <i>new-form-value</i> A Lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |              |                 |              |
| Description          | <p>A call to <code>replacement-source-form</code> can be used to allow the debugger and stepper to identify that <i>original-form</i> has been replaced by <i>new-form</i> in a macro expansion. Forms in a macro expansion that are <code>eq</code> to forms in the arguments to the macro will be identified automatically, but some macros (such as <code>iterate</code>) need to generate new forms that are equivalent to the original forms and wrapping them with <code>replacement-source-form</code> allows them to be identified too.</p> <p><i>original-form</i> should be a form that occurred in the arguments to the macro and does not otherwise occur in the expansion of the macro. <i>new-form</i> should be a form that was created by the macro.</p> |                      |              |                 |              |

The value of *new-form*, *new-form-value*, is returned when the **replacement-source-form** form is evaluated.

Examples Without the **dspec:replacement-source-form**, the calls to **pprint** would be unknown to the debugger and stepper because the forms do not occur in the original source code:

```
(defmacro pprint-for-print (&body forms)
  `(#(progn
      ,(loop for form in forms
             collect
             (if (and (consp form)
                       (eq (car form) 'print))
                 `(dspec:replacement-source-form
                   ,form
                   (pprint ,(cdr form)))
                 form))))
```

## save-tags-database

## *Function*

Summary Saves the current internal dspec database to a given file.

Package **dspec**

Signature **save-tags-database pathname => pathname**

Arguments *pathname* A filename.

Values *pathname* The filename that was supplied.

Description The function **save-tags-database** saves the current internal dspec database into the file given by *pathname*. The file can then be used in the variable **\*active-finders\***.

See also **\*active-finders\***

| Description                    | <p>The function <code>single-form-form-parser</code> is a predefined form parser for use with <code>define-form-parser</code>. The parser consumes one subform and returns a dspec made from the defining form and the subform. This can be used in the common case where a defining form has a name that follows the defining macro and the dspec class is the same as the defining macro, for example <code>defclass</code>.</p> <p><code>single-form-form-parser</code> is the predefined parser for <code>defvar</code>, <code>defparameter</code>, <code>defconstant</code>, <code>define-symbol-macro</code>, <code>define-compiler-macro</code>, <code>deftype</code>, <code>defsetf</code>, <code>define-setf-expander</code>, <code>defpackage</code>, <code>defclass</code>, <code>define-condition</code> and <code>define-method-combination</code> top level forms. It is also the parser for various LispWorks extensions such as <code>defsystem</code>.</p> <p>You can define it to be the parser for your defining forms. using <code>define-form-parser</code>.</p> |                              |

| Description | <p>The function <code>single-form-with-options-form-parser</code> is a predefined form parser for use with <code>define-form-parser</code>. The parser consumes one subform and returns a dspec made from the defining form and either the first element of the subform if it is a cons or the subform itself otherwise. This can be used in the common case where a defining form has a name with options that follows the defining macro and the dspec class is the same as the defining macro, for example <code>defstruct</code>.</p> <p><code>single-form-with-options-form-parser</code> is the pre-defined parser for <code>defstruct</code>, <code>fli:define-foreign-function</code>, <code>fli:define-foreign-variable</code>, <code>fli:define-c-struct</code>, <code>fli:define-c-union</code>, <code>fli:define-c-enum</code> and <code>fli:define-c-typedef</code> forms.</p> <p>You can define it to be the parser for your defining forms. using <code>define-form-parser</code>.</p> |

| Values      | <code><i>result</i></code>                                                                                                                                                                                                                                                                                                                                                  | A generalized boolean. |
| Description | <p>The function <code>traceable-dspec-p</code> determines whether the dspec <i>dspec</i> denotes a definition that can be traced using the Common Lisp macro <code>trace</code>.</p> <p><i>dspec</i> must not be a local dspec, and must be defined, according to <code>dspec-defined-p</code>. The result does not depend on whether <i>dspec</i> is currently traced.</p> |                        |
| Example     | <pre>CL-USER 67 &gt; (dspec:traceable-dspec-p '(subfunction                                          foo bar)) NIL</pre><br><pre>CL-USER 68 &gt; (dspec:traceable-dspec-p '(defun open)) OPEN</pre>                                                                                                                                                                         |                        |

|             | <i>Function</i>                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Gets and sets the global tracing state..                                                                                                                                                                  |
| Package     | <code>dspec</code>                                                                                                                                                                                        |
| Signature   | <code>tracing-enabled-p =&gt; enabledp</code><br><code>(setf tracing-enabled-p) enabledp =&gt; enabledp</code>                                                                                            |
| Values      | <code>enabledp</code> A generalized boolean.                                                                                                                                                              |
| Description | The function <code>tracing-enabled-p</code> determines whether tracing (by the Common Lisp macro <code>trace</code> ) is currently on. This is independent of whether any functions are currently traced. |

The function (`(setf tracing-enabled-p)`) switches tracing on or off according to the value of *enabledp*. This does not affect the list of functions that are currently traced.

| Arguments   | <b>dspec</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A dspec. |
| Values      | <b>state</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A list.  |
| Description | The function <b>tracing-state</b> returns a listing describing the current state of the tracing system. It shows the current tracing state for the dspec <i>dspec</i> , or for all traced definitions if <i>dspec</i> is not supplied.<br><br>The result <i>state</i> is a list each element of which is a list whose car is a dspec naming the traced definition and whose cdr is the additional trace options. Note that <b>tracing-state</b> returns more information than is returned by <b>trace</b> . It is useful for preserving a complex set of traces. |          |
|             | The function ( <b>(setf tracing-state)</b> ) sets the state of the tracing system. It changes the current tracing state for the dspec <i>dspec</i> , or for all traced definitions if <i>dspec</i> is not supplied.                                                                                                                                                                                                                                                                                                                                              |          |

(**setf tracing-state**) can be used to switch between different sets of traces. Note however that turning tracing on or off is better done using **tracing-enabled-p**.

## The EXTERNAL-FORMAT Package

This chapter describes symbols available in the `EXTERNAL-FORMAT` package, along with some of the actual external formats (typically with keyword names)

Use of these symbols are discussed in Chapter 26, “Internationalization: characters, strings and encodings”.

`:bmp`  
`:bmp-native`  
`:bmp-reversed`

*External Formats*

Summary      Implement reading and writing of 16-bit characters only (excluding supplementary characters).

Signature      `:bmp &key use-replacement little-endian`  
                 `:bmp-native &key use-replacement`  
                 `:bmp-reversed &key use-replacement`

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description         | <p>The external format <code>:bmp</code> and its variants implement reading and writing of 16-bit characters only (excluding supplementary characters).</p> <p><code>:bmp-native</code> and <code>:bmp-reversed</code> are the actual implementation formats. They implement reading and writing 16-bit characters with the native byte order (<code>:bmp-native</code>) or the reversed byte order (<code>:bmp-reversed</code>).</p> <p><code>:bmp</code> implements reading and writing 16-bit characters with control over the byte order. This format maps to either <code>:bmp-native</code> or <code>:bmp-reversed</code> as appropriate.</p> <p>If <i>little-endian</i> is supplied, it determines the byte order. Otherwise, if it is used for opening a file, the system checks whether the file starts with the BOM (Byte Order Mark), and if so it uses it. Otherwise the native byte order is used. The system uses the required byte order and the native byte order of the computer it executes on to decide whether to use <code>:bmp-native</code> or <code>:bmp-reversed</code>.</p> <p>When writing, these <code>:bmp</code> external formats signal an error when trying to write supplementary characters (code greater than <code>#xffff</code>).</p> <p><code>:bmp</code> cannot read surrogate code points. When encountering a surrogate code point it either signals an error (the default), or if <i>use-replacement</i> is non-nil, replaces it with the replacement character. When <i>use-replacement</i> is non-nil, these external formats never signal an error when reading.</p> |
| Compatibility note: | These formats were new in LispWorks 7.0. In LispWorks 6.1 and earlier versions <code>:unicode</code> is the external format to read 16-bit characters. Other than the treatment of surrogate code points, <code>:bmp</code> now does what <code>:unicode</code> used to do.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Summary            | Implements UTF-16 translation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |
| Signature          | <code>:unicode &amp;key <i>little-endian</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                        |
| Description        | <p>The external format <code>:unicode</code> implements UTF-16 translation, with default byte order the native one. <code>:unicode</code> is equivalent to <code>(:utf-16 :little-endian <i>little-endian</i>)</code> where the value of <i>little-endian</i> depends on the byte order of the native machine.</p> <p>When opening a file with <code>:external-format :unicode</code> (without passing <i>little-endian</i>), the system checks for the existence of the BOM (Byte Order Mark) in the beginning of the file, and if there is a BOM uses it to determine the correct byte order. Otherwise, it uses the native byte order. There are no checks for a BOM in other situations.</p> |                        |
| Notes              | <code>:unicode</code> differs from <code>:utf-16</code> when <i>little-endian</i> is not supplied and there is no BOM, because <code>:unicode</code> uses the native endianness and <code>:utf-16</code> uses big-endian. In all other circumstances <code>:unicode</code> is equivalent to <code>:utf-16</code> .                                                                                                                                                                                                                                                                                                                                                                               |                        |
| Compatibility note | In LispWorks 6.1 and earlier versions, <code>:unicode</code> reads only 16-bit characters, including character objects corresponding to surrogate code points. There is no exact match to that in LispWorks 7.0 and later, because there is no external format that reads surrogates. <code>:bmp</code> can be used to read 16-bit characters, either giving an error or using the replacement character for surrogate code points.                                                                                                                                                                                                                                                              |                        |
| See also           | “16-bit External formats guide” on page 445                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |
