|             | <i>asynchronous</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Boolean, default nil.                                 |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Always t.                                             |
| Description | <p>The function <code>setup-deliver-dynamic-library-for-java</code> prepares the LispWorks internal state for delivering (using <code>deliver</code>) a dynamic library that can be loaded from Java and use the Java interface.</p> <p><code>setup-deliver-dynamic-library-for-java</code> should be called just before calling <code>deliver</code>. It causes the call to <code>deliver</code> to produce a dynamic library even if the call to <code>deliver</code> is not given any keywords that indicate it should produce a dynamic library. When the delivered image is loaded into Java by <code>System.loadLibrary</code> or <code>System.load</code> (or the underlying <code>Runtime</code> methods), the host Java virtual machine is remembered by LispWorks and can be retrieved by calling <code>get-host-java-virtual-machine</code>, and if <code>init-java</code> is non-nil (the default) the Java interface is automatically initialized by a call to <code>init-java-interface</code>. Finally, if <code>function</code> is non-nil, it is then called with no arguments.</p> <p>The initialization of the Java interface and calling of <code>function</code> are done after the rest of the initialization of LispWorks. In particular, they occur after the <code>deliver</code> startup function (the first argument of <code>deliver</code>) has returned. If the <code>deliver</code> startup function does not return, the Java initialization does not occur.</p> |                                                       |

**asynchronous** controls whether the initialization is asynchronous from the Java point of view. When **asynchronous** is false (the default), the Java method that loads Lisp waits until Lisp has finished initialization, initialized the Java interface and **function** (if non-nil) has been called and returned. When **asynchronous** is true, the loading method returns immediately and LispWorks initializes asynchronously.

In the asynchronous case, calls from Java to Lisp (using methods in the `com.lispworks.LispCalls` class) may happen before Lisp is ready. Such calls are blocked until Lisp is ready, or 50 seconds have passed. If Lisp is not ready within 50 seconds, you will get an exception. It is possible to check if Lisp is ready by using `com.lispworks.LispCalls.waitForInitialization`.

There is a minimal example of delivering LispWorks for Java in:

```
(example-edit-file "java/lisp-as-dll/README.txt")
```

#### Notes

**function** is intended for performing Java-specific initialization after the Java interface has been initialized, including any initialization that requires the Java interface (which therefore cannot be done by the `deliver` startup function).

`setup-deliver-dynamic-library-for-java` works by setting up and exporting the C symbol `JNI_OnLoad`, which the loading methods in Java invoke. If you want to export your own `JNI_OnLoad`, you must not use `setup-deliver-dynamic-library-for-java`.

The function `get-host-java-virtual-machine` can be used to get the host Java virtual machine. In the synchronous case (the default), `get-host-java-virtual-machine` returns `nil` when called from the `deliver` startup function (first argument to `deliver`), because Lisp did not receive the Java virtual machine yet. In the asynchronous case, `get-host-java-virtual-machine` returns the virtual machine from the beginning.

A non-Java program can also load a dynamic library that was created by delivering with `setup-deliver-dynamic-library-for-java`. In this case, the Java interface is not initialized automatically, *function* is not called, and `get-host-java-virtual-machine` returns `nil`. `get-host-java-virtual-machine` can be used as predicate to tell whether the loading was done from a Java program or not.

If you want initialization that happens only when loaded by Java but not otherwise and you need this to happen before the Java interface is initialized, the easiest approach is to pass `nil` for *init-java* and pass, as *function*, a function that does your initialization and before calling `init-java-interface`. For example:

```
(setup-deliver-dynamic-library-for-java
  :init-java nil
  :function #'(lambda ()
    (my-java-pre-init)
    (init-java-interface)
    (my-java-post-init)))
```

If *init-java* is `nil`, you cannot use the Java interface until you call `init-java-interface`, as in the example above. The call to `init-java-interface` in this case can happen much later than the initialization, but note that calls from Java to Lisp that happen without checking if Lisp is ready will hang, and get an exception after 50 seconds.

In the asynchronous case with `nil` for *init-java*, `init-java-interface` can be called from the deliver startup function or later.

`setup-deliver-dynamic-library-for-java` modifies the way that `init-java-interface` looks for the virtual machine. In particular, you can call `init-java-interface` without specifying the Java virtual machine as in the example above, and `init-java-interface` will use `get-host-java-virtual-machine` to find it.

When `init-java` is true (the default), you can use `setup-java-interface-callbacks` to set some of the callbacks that in other situations you would pass to `init-java-interface`. `setup-java-interface-callbacks` should be called inside `function`, so they happen after the initialization of the Java interface.

LispWorks dynamic libraries that were delivered without using `setup-deliver-dynamic-library-for-java` can be loaded into Java, but to use the Java interface `init-java-interface` must be called with the Java virtual machine. It requires some expertise to pass the virtual machine to Lisp.

## setup-field-accessor *Function*

Summary      Defines a Java field accessor.

Package      `lw-ji`

Signature      `setup-field-accessor name class-name field-name static-p &optional is-final => result, error`

Arguments      `name`      A symbol.

`class-name`      A string.

`field-name`      A string.

`static-p`      A boolean.

`is-final`      A boolean.

Values      `result`      `name` or `nil`.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                   |

|             | <i>error</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A condition or <code>nil</code> . |
| Description | The function <code>setup-field-accessor</code> defines a field accessor for a field in a Java class.<br><br><code>class-name</code> must name a Java class.<br><br><code>field-name</code> must be a field name.<br><br><code>static-p</code> specifies whether the field is static or not.<br><br><code>is-final</code> specifies whether the field is final (read-only) or not.<br><br><code>setup-field-accessor</code> sets the symbol function of <code>name</code> to a function that reads the value of the field. If <code>is-final</code> is <code>nil</code> , it also defines <code>(setf name)</code> as the setter.<br><br>The arguments for the getter and setter are determined by the value of <code>static-p</code> . If <code>static-p</code> is non- <code>nil</code> , the getter takes no arguments and the setter takes the new value. If <code>static-p</code> is <code>nil</code> , the getter takes that object from which to get the value, and the setter gets the value and the object.<br><br><code>setup-field-accessor</code> looks up the field definition in Java, and if the definition is incorrect returns <code>nil</code> and the condition as the second value. |                                   |
| Notes       | In general, accessing fields should be avoided, because they are typically a less well-defined and implemented interface than methods, but sometimes it is necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                   |

| Description | <p>The functions <code>setup-java-caller</code> and <code>setup-java-constructor</code> define a Java caller, which is a function that calls a Java method or a constructor. Once this the caller is defined, calls to <code>name</code> ultimately invoke the Java method or constructor.</p> <p>Interpretation of the arguments and behavior of the defined caller is the same as the macros <code>define-java-caller</code> and <code>define-java-constructor</code>.</p> <p>Unlike the macros <code>define-java-caller</code> and <code>define-java-constructor</code>, the functions <code>setup-java-caller</code> and <code>setup-java-constructor</code> do the lookup immediately, and therefore require running Java. If the lookup fails, they do not set the symbol function, and return two values: <code>nil</code> and a condition indicating the reason for the failure.</p> <p>The functions (when successful) return <code>name</code>.</p> |

| Values      | <i>lisp-proxy-name</i> A symbol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | <p>The function <code>setup-lisp-proxy</code> defines a Lisp proxy, as described for <code>define-lisp-proxy</code>.</p> <p>Unlike <code>define-lisp-proxy</code> <i>name</i> can be <code>nil</code>, in which case <code>setup-lisp-proxy</code> generates a symbol by <code>c1:gensym</code>, uses it as the name and returns it.</p> <p><i>interface-and-method-descs</i> describes the Java interfaces to implement and the Lisp functions to call. <code>setup-lisp-proxy</code> takes it as a single argument, which must be a list, but otherwise parses it just like <code>define-lisp-proxy</code>.</p> |

| Description | <p>The class <code>standard-java-object</code> is a class for <code>jobject</code>. Instances of <code>standard-java-object</code> can be passed to the Java interface functions and callers you define, and returned from Java calls whenever a <code>jobject</code> is needed. Each instance is normally associated with a <code>jobject</code>, which is used by the Java interface.</p> <p>Apart from accessing the <code>jobject</code> in the instance, the Java interface does not do anything with the class, and makes no assumptions about it. There is no need for the class hierarchy in Lisp to reflect the class hierarchy in Java.</p> <p>You can define your own classes that inherit from <code>standard-java-object</code> as well as other classes using standard <code>def-class</code>. Alternatively, you can tell the importing interface to define classes. There is no obvious advantage for using the latter.</p> <p>The <code>jobject</code> slot defaults to <code>nil</code>, which the Java interface interprets as an invalid value. Your code needs to do something to set it. One option is to set it explicitly using the accessor <code>java-instance-jobject</code>. When you do that, the object must be a <code>jobject</code>, but the interface does not put any other restrictions. As long as it fits with the logic of your program, an instance of any Lisp class can hold a <code>jobject</code> of any Java class.</p> <p>The other way to set the <code>jobject</code> slot is to use one of the interface functions that does it implicitly. This include the functions <code>make-java-instance</code>, <code>create-instance-jobject</code> and <code>create-instance-jobject-list</code>, and the <code>:construct</code> keyword argument to <code>make-instance</code>.</p> |

The `:construct` keyword is processed by an `:after` method of `cl:initialize-instance` on `standard-java-object`. When `:construct` is supplied, it needs to be either a list (possibly `nil`) of arguments for the constructor, or `t`, which means use `default-constructor-arguments` to get the argument list. The method then calls `create-instance-jobobject-list` with the instance and the arguments to set create and set the `jobject`.

Additionally, the instance that is returned by `create-instance-from-jobobject` also has the `jobject`.

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | <p>When you pass <code>:construct t</code>, the call to <code>default-constructor-arguments</code> happens inside <code>cl:initialize-instance</code>, before all the <code>cl:initialize-instance</code> methods were called (the actual order of calls is the standard order). That means that if <code>default-constructor-arguments</code> depends on some values in the instance that may be set by an <code>cl:initialize-instance</code> method of another class, it may not work properly. You can avoid this problem by not passing the keyword <code>:construct</code> and instead using <code>create-instance-jobobject-list</code> on the result of <code>make-instance</code>.</p> <p>The interface for setting the <code>jobject</code> implicitly requires an association from the CLOS class name to the constructor, by using <code>define-java-constructor</code> or <code>setup-java-constructor</code> with the <code>class-symbol</code> argument.</p> <p><code>create-instance-from-jobobject</code> requires an association from the Java class name to the CLOS class name, which is created by <code>record-java-class-lisp-symbol</code>.</p> |

| Signature   | <code>throw-an-exception <i>exception-class-or-exception</i> &amp;rest <i>args</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments   | <p><i>exception-class-or-exception</i><br/> A string or a Java object.</p> <p><i>args</i>            Lisp objects.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The function <code>throw-an-exception</code> throws a Java exception from a proxy method invocation.</p> <p><code>throw-an-exception</code> must be called inside the function that is invoked from a proxy, otherwise a Lisp error is signaled. It causes throwing of a Java exception from the call.</p> <p><i>exception-class-or-exception</i> can be either a string naming an exception class or a Java object of an exception class. When it is a string, <code>throw-an-exception</code> constructs an exception of this class using <i>args</i> as arguments (same as <code>create-java-object</code>). If <i>exception-class-or-exception</i> is an exception then the <i>args</i> are ignored.</p> <p><code>throw-an-exception</code> throws in the Lisp sense out of your code, thus executing unwinding forms of surrounding <code>cl:unwind-protect</code>, and only then actually does the Java throwing (using JNI).</p> <p><code>throw-an-exception</code> can be used with the exception that is caught by <code>catching-java-exceptions</code>, if it is desired that the exception will be handled by the Java caller to the proxy. It is also needed when the method is documented to throw a specific exception in some situation.</p> |

## \*to-java-host-stream\* *Variable*

|         |                                                          |
|---------|----------------------------------------------------------|
| Summary | An output stream that sends its output to the Java host. |
|---------|----------------------------------------------------------|

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package       | <code>lw-ji</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Initial Value | An output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description   | The variable <code>*to-java-host-stream*</code> is bound globally to an output stream that sends any output that is written to it to the Java host, by calling <code>send-message-to-java-host</code> . The <i>where-keyword</i> argument to <code>send-message-to-java-host</code> is <code>:add</code> , so the output is added at the end and scrolled if needed. If you do not want scrolling, you can use <code>*to-java-host-stream-no-scroll*</code> instead.<br><br>See <code>send-message-to-java-host</code> for details. |
| Notes         | The connection to the Java host is made by <code>init-java-interface</code> . Until <code>init-java-interface</code> has been called, output to <code>*to-java-host-stream*</code> does nothing.<br><br><code>*to-java-host-stream*</code> is not buffered and makes frequent calls to <code>send-message-to-java-host</code> . This should be OK for dealing with a few kilobytes for each user gesture.                                                                                                                           |
| See also      | <code>send-message-to-java-host</code><br><code>*to-java-host-stream-no-scroll*</code>                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## **\*to-java-host-stream-no-scroll\*** *Variable*

|               |                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | An output stream that sends its output to the Java host without scrolling.                                                                                                                             |
| Package       | <code>lw-ji</code>                                                                                                                                                                                     |
| Initial Value | An output stream.                                                                                                                                                                                      |
| Description   | The variable <code>*to-java-host-stream-no-scroll*</code> is bound globally to an output stream that sends any output that is written to it to the Java host, by calling <code>send-message-to-</code> |

`java-host`. The *where-keyword* argument to `send-message-to-java-host` is `:add-no-scroll`, so the output is added at the end, without ever scrolling. If you want it to scroll when needed, you can use `*to-java-host-stream*` instead.

See `send-message-to-java-host` for details.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | The connection to the Java host is made by <code>init-java-interface</code> . Until <code>init-java-interface</code> is called, output to <code>*to-java-host-stream-no-scroll*</code> does nothing.<br><br><code>*to-java-host-stream-no-scroll*</code> is not buffered and makes frequent calls to <code>send-message-to-java-host</code> . This should be OK for dealing with a few kilobytes for each user gesture. |

| Arguments   | <code>name</code> A symbol.                                                                                                                                                                                                                                                                                                                                                                                              |  |
| Values      | <code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                           |  |
| Description | <p>The function <code>verify-java-caller</code> verifies the Java caller, which means looking up the corresponding Java methods and setting up the caller for <code>name</code>.</p> <p><code>name</code> must be a caller name defined by <code>define-java-caller</code> (but not any of the other definers or <code>setup-java-caller</code>). If it is not, an error is signaled. Note that the importing inter-</p> |  |

face defines the caller using `define-java-caller` and that `define-java-callers` also expands to `define-java-caller`, so `verify-java-caller` can be used on such caller (but not on constructors or field accessors).

`verify-java-caller` looks up the Java class and method of the caller (unless they are already cached), and caches the information (so future calls to *name* or verification can use it).

`verify-java-caller` returns `t` if successful, `nil` otherwise.

`verify-java-caller` requires running Java.

- Notes
1. In most cases using `verify-java-callers` to verify all the callers is more convenient.
  2. Verification is useful to guard against typing mistakes when you typed the `define-java-caller` explicitly because that does not do any lookup until run time, or when you are not sure that the class definition has not changed between the time you imported the definition and the time it is used.

## **verify-java-callers** *Function*

- Summary Verify all Java callers and return information about which was successful.

- Package `lw-ji`

- Signature `verify-java-callers &key classes return -> result`

- Arguments `classes` A list of strings, or `nil`.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                               |

| Description | <p>The function <code>verify-java-callers</code> verifies all Java callers and returns information about which was successful and which was not.</p> <p>If <i>classes</i> is non-nil, it must be a list of strings specifying Java classes. In this case, <code>verify-java-callers</code> verifies only callers for these classes. By default <code>verify-java-callers</code> verifies all callers that were defined by <code>define-java-caller</code>.</p> <p><i>return</i> specifies what to return. See below for details.</p> <p><code>verify-java-callers</code> maps through all the callers that were defined by <code>define-java-caller</code> on all classes (if <i>classes</i> is nil) or on the supplied <i>classes</i>.</p> <p>Note that the importing interface defines the caller using <code>define-java-caller</code> and that <code>define-java-callers</code> also expands to <code>define-java-caller</code>, so <code>verify-java-callers</code> verifies these callers too. <code>verify-java-callers</code> does not verify constructors or field accessors.</p> <p>For each caller, <code>verify-java-callers</code> looks up the Java class and the method of the caller (unless it is already cached), and caches the information so calls to the caller and future verifications can use it.</p> <p><code>verify-java-callers</code> returns a list containing an item for each failed lookup, except when <i>return</i> is the keyword <code>:successful</code>, in which case there is an item for each successful lookup. The value of each item depends on the value of <i>return</i> as follows:</p> <ul style="list-style-type: none"> <li><code>t</code> Each item is a cons (<code>args . condition</code>) where <code>args</code> is a list (<code>name class-name method-name</code>) of the required arguments of the <code>define-java-caller</code> form, and <code>condition</code> is the con-</li> </ul> |                                                                                                                                               |

dition that was produced when looking up. Unless something very unusual happened, this condition will be of type either `java-class-error` (if it failed to find the class) or `java-method-error` (if it failed to find the method).

|                          |                                                                                                                                                              |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:name-only</code>  | Each item is the name of the caller that failed.                                                                                                             |
| <code>:name</code>       | Each item is a cons where the <code>c1:car</code> is the name caller and the <code>c1:cdr</code> is the condition that was generated when trying the lookup. |
| <code>:info-only</code>  | Each item is the list ( <code>name class-name method-name</code> ) of the required arguments for <code>define-java-caller</code> of the failed caller.       |
| <code>:successful</code> | Each item is the name of a successful caller.                                                                                                                |

The default value of *return* is `t`.

`verify-java-callers` requires running Java.

Verification is useful to guard against typing mistakes when you typed the `define-java-callers` explicitly because that does not do any lookup until run time, or when you are not sure that the class definition has not changed between the time you imported the definition and the time it is used.

The intention is that you call `verify-java-callers` on starting your application, at least during the development phase, log the result and check it to see if anything is missing.

| Description | <p>The function <code>verify-lisp-proxy</code> verifies a single proxy definition.</p> <p>The function <code>verify-lisp-proxies</code> verifies all the proxy definitions that were defined by <code>define-lisp-proxy</code> (but not those created by <code>setup-lisp-proxy</code>).</p> <p>Verify means two things:</p> <ul style="list-style-type: none"> <li>• Check that all symbols in the definition which are not keywords have function definitions, and</li> <li>• Check that the methods that are declared in the interfaces that the definition uses have <i>method-specs</i>. This check is</li> </ul> |                                                                                                                                                                                                                                |                  |

performed only if *do-undefined-method* is non-nil, and requires running Java. The default value of *do-undefined-method* is `nil`.

`verify-lisp-proxy` returns two values:

*unbounds* reports symbols lacking function definitions. For each list in *unbounds*, its first element is the method name, and its second element is the symbol that is not fbound. If the default function is not fbound, there is a list where the first element is "`Default function`".

*undefined-methods* (if *do-undefined-method* is non-nil) can be either a string if one of the interfaces cannot be found (the string says that it cannot find an interface and gives its names), or a list. Each element in the list corresponds to an interface. The first element is the interface name, and the rest of the elements are strings specifying methods for which there is no matching *method-descs*.

`verify-lisp-proxies` maps through the proxy definitions that were defined by `define-lisp-proxy`, and verifies each one of them. It returns two values, a list for definitions with symbols are not fbound, and a list for definitions with methods that are undefined. Each item of *defs-with-unbounds* is a list corresponding to a definition with symbol not fbound, where the `c1:car` is the definition name and the `c1:cdr` is the *unbounds* list as returned by `verify-lisp-proxy`. Each item in *defs-with-undefined-methods* is a cons corresponding to a definition where a method is undefined, where the `c1:car` is the definition name and the `c1:cdr` is a string or a list of undefined methods as described above.

## Notes

Failure to find an interface is a real error, and will cause `make-lisp-proxy` to signal error when trying to make a proxy. Symbols which are not fbound and missing methods would cause the default function to be called, which may or may not be the intention. Symbols that are not fbound are useful when they are intended to be always overridden, in

which case they should be keywords, so verification ignores them.

| Values      | <i>java-class-name</i> | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description |                        | <p>The functions <code>write-java-class-definitions-to-file</code> and <code>write-java-class-definitions-to-stream</code> generate the definitions for the Java class named by <i>java-class-name</i>, and then write them to the destination specified by <i>filename</i> or <i>stream</i>.</p> <p>The generation of forms as the same as <code>generate-java-class-definitions</code> does, except that when <i>add-in-package</i> is non-nil <code>write-java-class-definitions-to-stream</code> and <code>write-java-class-definitions-to-file</code> insert a <code>cl:in-package</code> form after the package manipulation forms. The default value of <i>add-in-package</i> is non-nil.</p> <p>The arguments <i>java-class-name</i>, <i>lisp-name</i>, <i>lisp-class-p</i>, <i>package-name</i>, <i>name-constructor</i>, <i>prefix</i>, <i>export-p</i>, <i>create-defpackage</i> and <i>lisp-supers</i> are processed as described in the entry for <code>generate-java-class-definitions</code>.</p> <p>If <i>add-in-package</i> is non-nil, then after writing the package manipulation forms, a <code>cl:in-package</code> form is written with the package in which the definition names are interned, and the current package is bound to this package, which means the definition names do not need to be qualified with the package name.</p> <p><i>print-case</i> controls the binding of <code>cl:*print-case*</code> while outputting. The default value of <i>print-case</i> is <code>:downcase</code>.</p> <p><i>if-exists</i> is used by <code>write-java-class-definitions-to-file</code> when opening the file, in the same way as <code>open</code>.</p> |

`write-java-class-definitions-to-stream` generates the definitions for the class, and then writes all the definitions to the stream *stream*, with all the printer control variable set to the default except `cl:*print-case*` which takes its value from the *print-case* argument. It adds some comments, as lines starting with ";;".

`write-java-class-definitions-to-file` first open the file for output using the *filename* and *if-exists* arguments, and then calls `write-java-class-definitions-to-stream` with all the arguments except *filename* and *if-exists*.

`write-java-class-definitions-to-stream` and `write-java-class-definitions-to-file` return the *java-class-name*.

## Notes

1. `write-java-class-definitions-to-stream` and `write-java-class-definitions-to-file` require Java running, that is a working Java Virtual Machine and access to the definition of the class.

The generated code, however, is plain lisp, and can be compiled and loaded without Java. They allow you to use either of these functions once to generate the definitions, and add the output or file to your sources, and hence be able to compile and sources without running Java. Note that the output has no machine dependency at all. so as long as you can assume that the definition of the class does not change, you can output the definitions anywhere. For "globally public" classes (in the Java or Android packages), you can probably ask Lisp Support to generate the classes you need, and never bother with running Java on your development machine.

2. The output of these functions is all "user code", that is it uses only exported functions and macros that are available to user. It can be edited as desired, and definitions from it can be copied and used elsewhere.

3. `write-javascript-definitions-to-stream` is intended to allow writing the definitions of several classes to the same file. This especially useful when you write the definitions of several Java classes with the same package.

## Java classes and methods

This chapter describes the Java classes and methods available in LispWorks.

For an overview of this functionality with examples of use, see Chapter 15, “Java interface”.

### `com.lispworks.LispCalls`

*Java class*

#### Summary

```
public class com.lispworks.LispCalls implements  
InvocationHandler
```

The Java class `com.lispworks.LispCalls` defines methods for calling from Java to Lisp.

`com.lispworks.LispCalls` is part of the LispWorks distribution. For Android it is part of the `7-1-0-0/etc/lisp-works.jar` file. See the Chapter 16, “Android interface” for details. On other platforms it is defined in the JAR file `lisp-calls.jar` which is part of the LispWorks distribution in the `etc` directory, that is (`(lispworks-file "etc/lisp-calls.jar")`). This JAR file needs to be on the classpath (for example by the keyword argument `:java-class-path` to `init-java-interface`).

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | In the method name, the type specifies the return type, and v or A specifies whether the arguments are supplied as variable arguments or Array. Otherwise the pairs of v and A methods behave the same.<br><br>The <i>name</i> argument is a string specifying a Lisp symbol. The name is parsed by a simple parser as described for <code>com.lispworks.LispCalls.checkLispSymbol</code> (with <code>fboundp = true</code> ). |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If the symbol is not found or is not fbound, these methods throw a `RuntimeException` with a string giving the reason for failure.

If the symbol is found, it is applied to the arguments `args`. For each argument, if it is a primitive type or of a class corresponding to a primitive type or a string, it is converted to the corresponding Lisp value. Otherwise it is passed as a `jobject`. See “Types and conversion between Lisp and Java” on page 198. The result of the call is converted to the return type of the method and returned from the method. The conversion of the result type allows any float to be returned as a double, but does not coerce between integers and floats. For the `Object` return value, the result must be either a Java object (`jobject` or an instance of `standard-java-object`), or a Lisp object that can be converted to a Java object. See “Types and conversion between Lisp and Java” on page 198.

The Lisp function is an ordinary Lisp function, but it needs to return the right value. Unless the call is using the `void` callers (`com.lispworks.LispCalls.callVoidA` or `com.lispworks.LispCalls.callVoidV`), returning the wrong value will call the `java-to-lisp-debugger-hook` (see `init-java-interface`) with an appropriate condition, and then return zero of the correct type (that is 0, 0d0 or Java `null`) from the call.

The call to the Lisp function is wrapped such that trying to throw out of it does not actually finish the throw, and instead returns zero of the correct type from the call. It is also wrapped by a debugger hook, which is invoked if the code tries to enter the debugger (normally as a result of an unhandled error, but could be any call to `c1:invoke-debugger`). The hook calls the `java-to-lisp-debugger-hook` (see `init-java-interface`) with the condition, and then calls `c1:abort`. If there is no `c1:abort` restart inside the Lisp function that catches this abort, this causes returning a zero of the correct type.

An important issue to remember is that when delivering with shaking, LispWorks eliminates symbols for which there is no reference. If the only call to a Lisp symbol `foo` is from Java, LispWorks will not see the reference and it will eliminate `foo`. To guard against this, you can either pass `foo` in a list to the `deliver` keyword `:keep-symbols`, or more conveniently, use the function `hcl:deliver-keep-symbols` (see the *LispWorks Delivery User Guide*), for example:

```
(defun function-called-from-java (arg1 arg2)
  ...
)

(deliver-keep-symbols 'function-called-from-java)
```

|          |                                                                                                                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Examples | <pre>int sum = com.lispworks.LispCalls.callIntV ("+", 2, 3, 10); =&gt; sum = 15  int position = com.lispworks.LispCalls.callIntV ("search", "r", "international"); =&gt; position = 4  double logThree = com.lispworks.LispCalls.callDoubleV("log", 3); =&gt; logThree = 1.0986123</pre> |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## com.lispworks.LispCalls.checkLispSymbol *Method*

```
public static boolean checkLispSymbol(String name,
                                     boolean fboundp)
```

|             |                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>Checks whether a Lisp symbol exists, and optionally whether it is <code>fbound</code>.</p> <p><code>name</code> specifies the name of the Lisp symbol. The string <code>name</code> is parsed in a simple way, rather than using the Lisp reader. The parsing involves:</p> <ol style="list-style-type: none"> <li>1. Upcase the string.</li> </ol> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

2. If there is a colon, take the part before it as a package name. Otherwise use "COMMON-LISP-USER" as the package name.
3. If the colon is followed by another colon, skip it and set a flag allowing internals. Otherwise, set a flag allowing only externals.
4. Take the rest of the string as the symbol name.
5. Find the package from the package name.
6. Find the symbol using the package and the symbol name. If it is internal, use it only if the flag allowing internal was set.
7. If *fboundp* is `true`, check whether the symbol is fbound.

If all these steps succeed, `checkLispSymbol` returns `true`. Otherwise it returns `false`.

For symbols with names that do not need escaping, the result is the same normal processing by the Lisp reader without interning when there is no symbol.

`checkLispSymbol` caches the results in the Java side, which means that if the symbol appears or gets defined after the first call to `checkLispSymbol` it may return the wrong result.

|          |                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

## `com.lispworks.LispCalls.createLispProxy` *Method*

```
public static native Object createLispProxy(String
name)
```

|             |                                                                         |
|-------------|-------------------------------------------------------------------------|
| Description | Creates a Lisp proxy, which is a Java proxy which calls Lisp functions. |
|-------------|-------------------------------------------------------------------------|

*name* specifies a symbol which is the name of a proxy definition, defined in Lisp by either `define-lisp-proxy` or `setup-lisp-proxy`. The *name* is parsed by a simple parser as described for `com.lispworks.LispCalls.checkLispSymbol` (with `fboundp = false`).

Once it found the symbol, it makes a proxy the same way that calling `make-lisp-proxy` with *name* would, and returns it. The result is an object that implements all the interfaces that are defined in the proxy definition, and when the methods of these interfaces are called on the object it calls into Lisp. See `define-lisp-proxy` for details.

If `createLispProxy` is successful it returns the proxy object. If there is any problem, this will cause a call to `c1:error`. If the `c1:error` call is not handled, the `java-to-lisp-debugger-hook` (see `init-java-interface`) is called with the condition, and then `null` is returned from `createLispProxy`. If the error is handled and tries to throw out of the context of the Lisp side of `createLispProxy`, the throw is blocked and `createLispProxy` returns `null`.

|                                                      |               |
|------------------------------------------------------|---------------|
| <b>com.lispworks.LispCalls.waitForInitialization</b> | <i>Method</i> |
|------------------------------------------------------|---------------|

```
static public boolean waitForInitialization ()

static public boolean waitForInitialization (long
seconds)

static public boolean waitForInitialization (long
timeout , java.util.concurrent.TimeUnit unit)
```

|             |                                                                                          |
|-------------|------------------------------------------------------------------------------------------|
| Description | Waits for a LispWorks dynamic library to finish initialization and accept foreign calls. |
|-------------|------------------------------------------------------------------------------------------|

Note: You should not use `waitForInitialization` on Android. Use the methods in `com.lispworks.Manager` instead, in particular `com.lispworks.Manager.init` and `com.lispworks.Manager.status`.

The method without arguments waits for up to 10000 seconds. The method that takes `long` waits for up to `seconds` seconds. The method that takes `long` and

`java.util.concurrent.TimeUnit` waits for up to the period defined by `timeout` and `unit`. See the Java documentation for the possible values of `java.util.concurrent.TimeUnit`.

`waitForInitialization` returns when LispWorks has finished its initialization or when the wait period has passed. If LispWorks finishes its initialization first, `waitForInitialization` returns true. If the wait period has passed, `waitForInitialization` returns false.

When `waitForInitialization` is called with 0 seconds, it returns immediately with true if LispWorks is already initialized, and false otherwise. Thus it can be used as a predicate without waiting.

**Notes** Until LispWorks finishes its initialization, calls into LispWorks from Java using the other methods in `com.lispworks.LispCalls` hang, and raise an exception if hanging for too long. If this is an acceptable behavior, then you do not need `waitForInitialization`. If this is not acceptable, `waitForInitialization` allows you to check and avoid this situation. Typically your code will do something like:

```
if (com.lispworks.LispCalls.waitForInitialization(1))
    com.lispworks.LispCalls.callIntV("A-LISP-FUNCTION");
else
    do_something_else();
```

If the LispWorks dynamic library was created with synchronous initialization (the default), then by the time the loading method (normally `System.loadLibrary` or `System.load`) returns, LispWorks has finished initializing. In this case you need `waitForInitialization` only in code that does not know if the loading method has returned (or even called at all).

If the LispWorks dynamic library was created with asynchronous initialization (`setup-deliver-dynamic-library-for-java` was called with true for `asynchronous`), the loading method returns immediately, and LispWorks initializes asynchronously. In this situation you can be sure that LispWorks finished initializing only after a call to `waitForInitialization` has returned true.

If you don't know how the LispWorks dynamic library was created, just assume that it is asynchronous and always check using `waitForInitialization`.

## Android Java classes and methods

This chapter describes the Android interface Java code.

For an overview of this functionality with examples of use, see Chapter 16, “Android interface”.

### **com.lispworks.Manager** *Java class*

#### Summary

```
public class com.lispworks.Manager
```

A Java class that defines methods for using Lisp on Android .

It contains one essential method, `com.lispworks.Manager.init`, which loads and initializes LispWorks. It also contains methods to set error reporters that will get called when an error inside Lisp is not caught by user handlers or when `report-error-to-java-host` is called, some methods to define where messages from Lisp (calls to `send-message-to-java-host` or `format-to-java-host`) go, and some other utilities.

`com.lispworks.Manager` defines these methods and fields:

## Initialization

```

public static int init(Context context , String
deliverName, Runnable reporter)

public static int init(Context context)

public static int init(Context context, Runnable reporter)

public static int init(Context context, String
deliverName)

public static int status()

public static int init_result_code()

public static String mInitErrorString = ""

public static boolean loadLibrary()

public static boolean loadLibrary(String deliverName)

final public static int STATUS_INITIALIZING = 0
final public static int STATUS_READY = 1
final public static int STATUS_NOT_INITIALIZED = -1
final public static int STATUS_ERROR = -2

final public static int INIT_ERROR_NO_LIBRARY = -2000
final public static int INIT_ERROR_NO_ASSET = -2001
final public static int INIT_ERROR_FAIL_HEAP = -2002

```

## Error handling

```

public static void setErrorReporter(LispErrorReporter
ler)

public static void
setGuiErrorReporter(LispGuiErrorReporter ler)

public interface LispErrorReporter

public interface LispGuiErrorReporter

public static synchronized void clearBugFormLogs(int
count)

```

```
public static void showBugFormLogs(Activity act)
public static String mInitErrorString = ""
public static int mMaxErrorLogsNumber = 5
```

## Message handling

```
public interface MessageHandler
public void setMessageHandler(MessageHandler handler)
public static synchronized void
setTextView(android.widget.TextView textView)
public static void addMessage(String message, int where)
public static int mMessagesMaxLength
final public static int ADDMESSAGE_RESET = 0
final public static int ADDMESSAGE_APPEND = 1
final public static int ADDMESSAGE_PREPEND = 2
final public static int ADDMESSAGE_APPEND_NO_SCROLL = 3
final public static int ADDMESSAGE_ADD = 4
final public static int ADDMESSAGE_ADD_NO_SCROLL = 5
```

## Others

```
public static void
setCurrentActivity(android.app.Activity)
public static ClassLoader getClassLoader()
public static Context getApplicationContext()
```

Notes      The `com.lispworks.Manager` class is part of the LispWorks distribution, inside the `lispworks.jar` file.

See also    “Delivering for Android” on page 224

## com.lispworks.Manager.init

### Method

```
public static int init(Context context)
public static int init(Context context, Runnable reporter)
```

```
public static int init(Context context, String
deliverName)
```

```
public static int init(Context context, String
deliverName, Runnable reporter)
```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>Load and initialize Lispworks asynchronously.</p> <p><code>init</code> first checks whether LispWorks is already initialized or in the process of initializing, and if it is returns immediately the appropriate value (<code>STATUS_READY</code> or <code>STATUS_INITIALIZING</code>). Otherwise it loads LispWorks, and initiates the initialization process on another thread. It returns before initialization finished.</p> <p>The argument <code>context</code> is any object of class <code>android.content.Context</code>. <code>init</code> uses it to find the application context, and hence where the LispWorks heap is.</p> <p>The argument <code>reporter</code> is a <code>Runnable</code> that is invoked (that is its run method is invoked) when LispWorks finished initialization. The invocation is on the main thread. The <code>reporter</code> in general should use <code>com.lispworks.Manager.status</code> to check that initializing LispWorks succeeded. Once the <code>reporter</code> is invoked and <code>com.lispworks.Manager.status</code> returned <code>STATUS_READY</code>, it is possible to make calls into Lisp by methods in <code>com.lispworks.LispCalls</code>. If <code>reporter</code> is not supplied, it is possible to know that LispWorks is ready by two other mechanisms:</p> <ul style="list-style-type: none"> <li>• Use the <code>com.lispworks.Manager.status</code> method from other places, or</li> <li>• Call from Lisp into Java from the restart <i>function</i> (the first argument to <code>deliver-to-android-project</code>). When this restart <i>function</i> runs, LispWorks is already ready.</li> </ul> <p>The argument <code>deliverName</code> specifies the name of the delivered LispWorks, specifically the base name of the heap and the dynamic library. See <code>deliver-to-android-project</code> for discussion. The default for <code>deliverName</code> is "LispWorks", which is</p> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

the default in `deliver-to-android-project`, so normally you do not need it.

`init` returns one of the `STATUS_*` constants. See the entry for `com.lispworks.Manager.status`.

`init` can be called repeatedly and it is thread-safe. The second and subsequent calls will not try to initialize it, unless the status is `STATUS_ERROR`, in which case it will try again. Each *reporter* that is passed to `init` is called independently. This is designed so if your application does not initialize LispWorks on startup, each part of it that relies on LispWorks can use `com.lispworks.Manager.status` to check whether LispWorks is ready, and if not call `init` with a *reporter*, and when the *reporter* is invoked check that `com.lispworks.Manager.status` returns `STATUS_READY`, and then rely on working LispWorks.

## `com.lispworks.Manager.status`

### *Method and Fields*

```
public static int status()

final public static int STATUS_INITIALIZING = 0
final public static int STATUS_READY =1
final public static int STATUS_NOT_INITIALIZED = -1
final public static int STATUS_ERROR = -2
```

Description

Return the status of LispWorks:

`STATUS_INITIALIZING`

LispWorks started initializing but has not finished yet. Because `com.lispworks.Manager.init` is asynchronous, it typically returns this value.

`STATUS_READY`

LispWorks finished initializing.

**STATUS\_NOT\_INITIALIZED**

LispWorks has not started initializing, that is before `com.lispworks.Manager.init` was called.

**STATUS\_ERROR**

There was an error during initialization that prevented initialization. The method `com.lispworks.Manager.init_result_code` and the field `com.lispworks.Manager.mInitErrorString` gives more information about the reason for failure.

`com.lispworks.Manager.init`  
`com.lispworks.Manager.init_result_code`  
`com.lispworks.Manager.mInitErrorString`  
“Delivering for Android” on page 224

## `com.lispworks.Manager.init_result_code`

## *Method and Fields*

```
public static int init_result_code()

final public static int INIT_ERROR_NO_LIBRARY = -2000
final public static int INIT_ERROR_NO_ASSET = -2001
final public static int INIT_ERROR_FAIL_HEAP = -2002
```

Description

Return a more detailed code specifying the result of the call to `com.lispworks.Manager.init`. The code is either one of the three `INIT_ERROR_*` constants above, or one of the codes that `InitLispWorks` returns.

`INIT_ERROR_NO_LIBRARY`

`com.lispworks.Manager.init` did not find the library.

Normally that would mean it is not in the project where it should be (`libs/armeabi-v7a` for Eclipse, `jnilibs/armeabi-v7a` for Android Studio), or its name is not correct. See [deliver-to-android-project](#) for details.

#### `INIT_ERROR_NO_ASSET`

`com.lispworks.Manager.init` failed to find the LispWorks heap in the assets. Normally that means that the LispWorks heap is missing from the project (it should be in assets), or its name is incorrect. See [deliver-to-android-project](#) for details.

#### `INIT_ERROR_FAIL_HEAP`

Extracting the heap from the assets failed. That in general should not happen. It may happen if the disk on the system is full.

Other values are documented for `InitLispWorks`. In general:

- 0 or greater means success (`com.lispworks.Manager.status` returns `STATUS_READY`).
- Values greater than -100 and lower than 0 mean timeout. Since `com.lispworks.Manager.init` is asynchronous, that would be the values during initialization (`com.lispworks.Manager.status` returns `STATUS_INITIALIZING`).
- -100 means not initialized (`com.lispworks.Manager.status` returns `STATUS_NOT_INITIALIZED`).
- Values lower than -100 indicate an error (`com.lispworks.Manager.status` returns `STATUS_ERROR`).

`init_result_code` would typically be used after `com.lispworks.Manager.status` returned `STATUS_ERROR`

When there is an error, `com.lispworks.Manager.mInitErrorString` contains a string describing it.

See also      `com.lispworks.Manager.mInitErrorString`  
`com.lispworks.Manager.init`  
`com.lispworks.Manager.status`  
`deliver-to-android-project`  
“Delivering for Android” on page 224

## **com.lispworks.Manager.mInitErrorString** *Field*

```
public static String mInitErrorString = ""
```

Description      Contains a string explaining the result for an error during initialization.  
  
`mInitErrorString` is set to a non-empty string if there is an error during initialization of LispWorks, which would be detected either by using `com.lispworks.Manager.status` or `com.lispworks.Manager.init_result_code`.  
  
The explanation is technical, so it will not be useful to show it to end users, but it should be helpful to developers, and certainly to LispWorks support.

See also      `com.lispworks.Manager.init`  
`com.lispworks.Manager.status`  
`com.lispworks.Manager.init_result_code`  
“Delivering for Android” on page 224

## **com.lispworks.Manager.loadLibrary** *Method*

```
public static boolean loadLibrary()  
  
public static boolean loadLibrary(String deliverName)
```

Description      Loads only the LispWorks dynamic library without initializing, for debugging.  
  
Normally `loadLibrary` is called by `com.lispworks.Manager.init`, and in general you should not use it. It is supplied because it is sometimes useful for debugging.

`com.lispworks.Manager.init` can be called after `loadLibrary` was called, and will skip the call to it in this case.

`deliverName` has the same meaning as in `com.lispworks.Manager.init`.

Note that `loadLibrary` is not thread-safe on its own.

`loadLibrary` returns `true` on success, otherwise it returns `false` and sets `com.lispworks.Manager.mInitErrorString`

See also      `com.lispworks.Manager.init`  
                `com.lispworks.Manager.mInitErrorString`

`com.lispworks.Manager.LispErrorReporter`

`com.lispworks.Manager.setErrorReporter`

`com.lispworks.Manager.LispGuiErrorReporter`

`com.lispworks.Manager.setGuiErrorReporter` *Methods and Interfaces*

```
public interface LispErrorReporter {
    boolean report(String errorString, String filename);
}

public static void setErrorReporter(LispErrorReporter ler)

public interface LispGuiErrorReporter {
    boolean report(String errorString, String filename);
}

public static void
setGuiErrorReporter(LispGuiErrorReporter ler)
```

Description      Set error reporters that gets invoked when either `report-error-to-java-host` is called, or an error is not caught by your handler or hook.

`setErrorReporter` and `setGuiErrorReporter` are used to set error reporters. When either `report-error-to-java-host` is called (by your code, the system does not use it) or an error is not handled by your handlers (including debugger-

wrappers and `cl:*debugger-hook*)`, the `report` method of the interface is invoked. By default the reporters are both `null`.

The `errorString` of the report message is a string describing the error. The `filename` is the name of a file that contains a log file, but can be also `null`.

**Note:** when `report-error-to-java-host` is called it is your responsibility to pass the right strings.

The reporters should do whatever you want to do. The return value should indicate if the error was dealt with completely, so there is no need to call `com.lispworks.Manager.addMessage` (see below).

The reporter that is set by `setErrorReporter` (“the Lisp error reporter”) and the reporter that is set by `setGuiErrorReporter` (“the Lisp GUI error reporter”) differ by the scope in which their `report` method is invoked:

- The `report` method of the Lisp error reporter is invoked within the scope of the error, which also means it can be any thread. It is therefore cannot do anything related to the GUI, and needs to be runnable on any thread. In general, it should only set internal variables and return, but it may also do things like copying the log file somewhere.
- The `report` method of the Lisp GUI error reporter is invoked outside the scope of the error, on the GUI thread. It is done by the event loop of the GUI thread, so it is also synchronous with respect to processing events. It can therefore safely access the GUI and perform what is needed to inform the user that an error has occurred.

`setErrorReporter` and `setGuiErrorReporter` can be called at any time, before or after `com.lispworks.Manager.init`. There is only one Lisp error reporter and one Lisp GUI error reporter, and each call to `setErrorReporter`

or `setGuiErrorReporter` overwrites the previous value. The reporters can be set to `null`.

When Lisp calls into Java to report an error, it does the following steps:

1. If `com.lispworks.Manager.mMaxErrorLogsNumber` is greater than 0, records the error and delete previous record(s) if the number of records reached `com.lispworks.Manager.mMaxErrorLogsNumber` (these records can be displayed by `com.lispworks.Manager.showBugFormLogs`).
2. If the Lisp error reporter (the non-GUI one) is not `null`, invoke its `report` method.
3. If the Lisp GUI error reporter is not `null`, arrange for its `report` method to be invoked on the GUI process, and does the next 2 steps after this invocation.
4. If neither of the reporters returned `true`, use `com.lispworks.Manager.addMessage` to append the error message. See documentation for `com.lispworks.Manager.addMessage`.
5. If `com.lispworks.Manager.mMaxErrorLogsNumber` is not greater than 0, delete the log file if it is not `null`.

|       |                                                                                                                                                                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | The log files are deleted when LispWorks starts (when <code>com.lispworks.Manager.init</code> is successful). They are also in the internal cache directory, which means they are not visible to other applications. If you want to make the logs visible, the reporter needs to copy the file to an external directory. |

**com.lispworks.Manager.clearBugFormLogs** *Method*

```
public static synchronized void clearBugFormLogs(int
count)
```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>Clear the bug form logs list.</p> <p>LispWorks keeps a record of error reports containing the error strings and the file names containing the log (the arguments to the <code>report</code> method of <code>com.lispworks.Manager.LispErrorReporter</code> received). <code>clearBugFormLogs</code> eliminates all entries except the last <code>count</code> entries, and removes the files.</p> <p>The record is limited to <code>com.lispworks.Manager.mMaxErrorLogsNumber</code>, which defaults to 5.</p> <p>The record can be displayed by <code>com.lispworks.Manager.showBugFormLogs</code>, which allows the user to open the log file of a record by selecting it.</p> |
| Notes       | The log files are also automatically deleted when LispWorks starts (that is when <code>com.lispworks.Manager.init</code> is successful).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| See also    | <code>com.lispworks.Manager.setErrorReporter</code><br><code>com.lispworks.Manager.mMaxErrorLogsNumber</code><br><code>com.lispworks.Manager.showBugFormLogs</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**com.lispworks.Manager.mMaxErrorLogsNumber** *Field*

```
public static int mMaxErrorLogsNumber = 5
```

|             |                                                                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>Maximum number of error logs to keep.</p> <p>The default value of 5 is a compromise between keeping many logs (in case some are useful) and avoiding filling the disk. During development you may want to enlarge it, and in the finished product maybe reduce it, possibly to 0.</p> <p>The log files are deleted when LispWorks is initialized.</p> |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## com.lispworks.Manager.showBugFormLogs

### Method

```
public static void showBugFormLogs(Activity act)
```

#### Description

This method is for debugging.

`showBugFormLogs` shows a list of the `BugFormLogs`, where each item is an error string, and allows you to open the associated log file by touching the item. If there is only one item, it opens it immediately.

The argument `act` is the activity that invokes the bug list.

The bug list is displayed in its own activity, `com.lispworks.BugFormLogsList`, and the log file is opened to another activity, `com.lispworks.BugFormViewer`. To make `showBugFormLogs` work, you must add these activities to the file `AndroidManifest.xml` in your project like this:

```
<activity android:name="com.lispworks.BugFormViewer"  
        android:label="Bug Form viewer"> </activity>  
<activity android:name="com.lispworks.BugFormLogsList"  
        android:label="Bug Form Logs"> </activity>
```

The `AndroidManifest.xml` of the OthelloDemo examples contains these lines. Apart from putting the activities in the `AndroidManifest.xml`, you should not do anything else with them.

This method shows Lisp bug forms, so is useful only for Lisp developers.

There will not be any bug form logs if there was no error, or `com.lispworks.Manager.mMaxErrorLogsNumber` is set to 0, in which case `showBugFormLogs` does nothing. It is also possible for the user error reporters (see `com.lispworks.Manager.setErrorReporter`) to delete the log files, so `com.lispworks.BugFormViewer` will fail to show it.

`showBugFormLogs` is useful during development. Once the application is working, you probably want to remove the activities from `AndroidManifest.xml` and not use `showBugFormLogs`.

**com.lispworks.Manager.addMessage****com.lispworks.Manager.mMessagesMaxLength      Method and Fields**

```
public static void addMessage(String message, int where)
public static int mMessagesMaxLength = 10000

final public static int ADDMESSAGE_RESET = 0
final public static int ADDMESSAGE_APPEND = 1
final public static int ADDMESSAGE_PREPEND = 2
final public static int ADDMESSAGE_APPEND_NO_SCROLL = 3
final public static int ADDMESSAGE_ADD = 4
final public static int ADDMESSAGE_ADD_NO_SCROLL = 5
```

**Description**

Adds a message.

The actual meaning of adding a message is either to call the message handler if it was set by `com.lispworks.Manager.setMessageHandler`, or put the message in the output text view if it was set by `com.lispworks.Manager.setTextView`, if neither the handler or the view are set, then `addMessage` accumulates the messages, and inserts the text next time that that `com.lispworks.Manager.setTextView` is called.

The operation of `addMessage` is first to check whether the handler is not `null`, and if it is call the handler with the two arguments. If the handler returns `true`, `addMessage` does not do anything else. Otherwise, if there is a textview it adds the message to it, otherwise it adds the message to its own buffer.

`where` needs to be one of the six `ADDMESSAGE_*` constants, and determines how the message is added. `ADDMESSAGE_RESET` causes `addMessage` to first clear the textview or the internal string before adding the message. `ADDMESSAGE_PREPEND` means adding the string at the beginning of the textview or

internal string, followed by a newline. `ADDMESSAGE_APPEND`, `ADDMESSAGE_APPEND_NO_SCROLL`, `ADDMESSAGE_ADD` and `ADDMESSAGE_ADD_NO_SCROLL` all add the message to the end of the textview or internal string. `ADDMESSAGE_APPEND` and `ADDMESSAGE_APPEND_NO_SCROLL` follow the message by a newline, while the `ADDMESSAGE_ADD` and `ADDMESSAGE_ADD_NO_SCROLL` do not.

`ADDMESSAGE_APPEND_NO_SCROLL` and `ADDMESSAGE_ADD_NO_SCROLL` do not scroll, while `ADDMESSAGE_APPEND` and `ADDMESSAGE_ADD` scroll the textview to make at least the top of the new message visible.

`addMessage` is used by LispWorks to perform the operation of `send-message-to-java-host`, and to report errors which are not dealt with by the error reporters. You can use it when it is useful.

The call to the handler is done on the thread on which `addMessage` is called, so the handler must be able to cope with being called on any thread, and needs to be thread-safe. The access to the textview or the internal string is done on the GUI thread and is thread-safe.

`mMessagesMaxLength` limits the length that `addMessage` accumulates. The length of the text that `addMessage` accumulates, either internally or in the `TextView`, is limited to the value `mMessagesMaxLength` (default 10000). When appending causes the length to overflow this value, `addMessage` removes the beginning of the old accumulated text so the total is limited to `mMessagesMaxLength`. However, it does not remove part of the message itself, so calling `addMessage` with a string longer than `mMessagesMaxLength` will cause the `TextView` or internal string to be longer than `mMessagesMaxLength` (the old text would be removed completely in this case).

Compatibility notes

`ADDMESSAGE_ADD` and `ADDMESSAGE_ADD_NO_SCROLL` are new in LispWorks 7.1. In LispWorks 7.0, the `ADDMESSAGE_APPEND` and `ADDMESSAGE_APPEND_NO_SCROLL` inserted the newline

before the message. If you rely on that, you may have to modify your code.

**com.lispworks.Manager.setMessageHandler****com.lispworks.Manager.MessageHandler** *Method and Interface*

```
public void setMessageHandler(MessageHandler handler) {
    mMessagehandler = handler }

public interface MessageHandler {
    boolean handle(String message, int where);
}
```

## Description

Sets the message handler which `com.lispworks.Manager.addMessage` uses.

The `handler` is `null` by default, and can be set to `null`.

When the `handler` is not `null`, `com.lispworks.Manager.addMessage` calls the `handle` method with its arguments. The result tells

`com.lispworks.Manager.addMessage` whether to deal further with the string, see its reference entry for further details.

Note that the `handler` can be called on any thread, and needs to be thread-safe.

[com.lispworks.Manager.addMessage](#)

**com.lispworks.Manager.setTextView***Method*

```
public static synchronized void
setTextView(android.widget.TextView textview)
```

Description Sets the textview for `com.lispworks.Manager.addMessage`.

The `textview` defaults to `null` and can be set to `null`. When it is `null`, `com.lispworks.Manager.addMessage` accumulates the message.

When `setTextView` is called, if there is already a textview it takes the content first and puts it in the buffer of `com.lispworks.Manager.addMessage`. If the new value `textview` is not `null`, it puts into it the buffer of `com.lispworks.Manager.addMessage` and clears the buffer. This is designed such that you can set the `TextView` to another `TextView` or to `null` without losing text.

The intention is that `TextView` makes it easy to display messages that come from Lisp. In a fully-developed product you probably want a better mechanism, by setting the message handler with `com.lispworks.Manager.setMessageHandler`.

There is no expectation by `setTextView` or `com.lispworks.Manager.addMessage` about the properties of the `TextView` except that it is possible to add text to it and delete all the text from it. You can manipulate it yourself (for example delete all the text, or all the text except the last 100 lines) while is set.

`setTextView` can be called on any thread, and is thread-safe. The manipulation of the `TextView` by `com.lispworks.Manager.addMessage` is always done on the GUI process,

**com.lispworks.BugFormViewer**                            *Java class*

```
public class BugFormViewer extends Activity
```

Description      Used by `com.lispworks.Manager.showBugFormLogs` to show an individual log.

See also      `com.lispworks.Manager.showBugFormLogs`

# The MP Package

This chapter describes symbols available in the `mp` package, giving you access to the multiprocessing capabilities of LispWorks.

Multiprocessing is discussed in detail in Chapter 19, “Multiprocessing”.

## **allowing-block-interrupts** *Macro*

**Summary** Allows control over blocking interrupts.

**Package** `mp`

**Signature** `allowing-block-interrupts start-blocked &body body => results`

**Arguments** `start-blocked` A generalized boolean

`body` Code

**Values** `results` Values returned by evaluating `body`.

**Description** The macro `allowing-block-interrupts` executes `body` allowing control over blocking interrupts by `current-pro-`

`process-unblock-interrupts` and `current-process-unblock-interrupts`.

Within the dynamic scope of `allowing-block-interrupts`, you can switch the blocking of interrupts on and off. Blocking interrupts prevents any interruption of the current process, including `process-interrupt`, `process-kill`, `process-reset`, `process-break` and `process-stop`. These interrupts are all queued and processed once interrupts become unblocked.

Blocking interrupts also blocks interrupts due to POSIX signals. Such interrupts are processed either by another Lisp thread, or once interrupts become unblocked.

If `start-blocked` is true, `allowing-block-interrupts` blocks interrupts on entry. If `start-blocked` is false, the state does not change on entry. If you want to ensure that the initial forms of `allowing-block-interrupts` are interruptible even if it is inside the scope of another `allowing-block-interrupts`, you need to explicitly call `current-process-unblock-interrupts` on entry.

`allowing-block-interrupts` can be used recursively.

In compiled code, `allowing-block-interrupts` with a true value of the `start-blocked` argument is guaranteed not to process interrupts before an explicit change to the blocking state (that includes exiting the scope of `allowing-block-interrupts`). In particular, if the first cleanup form of an `unwind-protect` is a call to `allowing-block-interrupts`, it is guaranteed to execute without interrupts on exit from the protected form. No such guarantee is given in interpreted code.

On exit from `allowing-block-interrupts`, the current state of interrupt blocking and whether there is a surrounding use of `allowing-block-interrupts` OR with-interrupts-blocked is restored to the state that existed on entry.

`allowing-block-interrupts` returns the results of `body`.

## any-other-process-non-internal-server-p

## *Function*

**Summary** Tests whether there is any other process except the caller that is not marked as "internal server".

## Package mp

Signature any-other-process-non-internal-server-p => result

Arguments      None.

Values              *result*              A boolean.

Description The function `any-other-process-non-internal-server-p` is the predicate for whether there is any other process, except the caller process, that is not marked as "internal server".

**Notes** Processes are marked as "internal server" by a true value for `:internal-server` amongst the *keywords* in a call to `process-run-function`.

See also [process-run-function](#)  
[process-internal-server-p](#)

**barrier** *System Class*

|              |                                                                                                                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | A class of objects for synchronizing processes.                                                                                                                                                                  |
| Package      | <code>mp</code>                                                                                                                                                                                                  |
| Superclasses | <code>t</code>                                                                                                                                                                                                   |
| Description  | Instances of the system class <code>barrier</code> are used for synchronizing processes. They are made by <code>make-barrier</code> and <code>barrier-wait</code> is typically called at synchronization points. |

**barrier-arriver-count** *Function*

|             |                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the arriver count of a <code>barrier</code> .                                                                                                                    |
| Package     | <code>mp</code>                                                                                                                                                          |
| Signature   | <code>barrier-arriver-count barrier =&gt; result</code>                                                                                                                  |
| Arguments   | <code>barrier</code> A <code>barrier</code> .                                                                                                                            |
| Values      | <code>result</code> A positive fixnum, or <code>nil</code> .                                                                                                             |
| Description | The function <code>barrier-arriver-count</code> returns the arriver count of the <code>barrier</code> <code>barrier</code> , or <code>nil</code> for a disabled barrier. |
| Notes       | If <code>barrier</code> is in use, the arriver count can change at any time.                                                                                             |
| See also    | <code>barrier</code><br><code>barrier-wait</code>                                                                                                                        |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <b>barrier-block-and-wait</b> enables the <b>barrier</b> <i>barrier</i> with <i>t</i> , that is it makes any number of arrivers wait, and then waits until <i>count</i> arrivers arrive. |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|  |                                                                                                                                                                                |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | <i>wait-if-used-p</i> controls whether to wait if another process is already inside <b>barrier-block-and-wait</b> . The default value of <i>wait-if-used-p</i> is <b>nil</b> . |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|  |                                                                  |
|--|------------------------------------------------------------------|
|  | <i>barrier</i> is a <b>barrier</b> made by <b>make-barrier</b> . |
|--|------------------------------------------------------------------|

|  |                                                                                                                                                                                                                   |
|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | <i>errorp</i> controls whether to signal an error if another process is already inside <b>barrier-block-and-wait</b> and <i>wait-if-used-p</i> is <b>nil</b> . The default value of <i>errorp</i> is <b>nil</b> . |
|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*timeout*, if non-nil, specifies the time in seconds to wait before timing out. The default value of *timeout* is `nil`.

*unlock* specifies whether processes that already wait on *barrier* should be unblocked first. The default value of *unlock* is `nil`.

`barrier-block-and-wait` is "using" *barrier*, and only one process can do this the same time. `barrier-block-and-wait` first tries to mark *barrier* as used by the current process, which will fail if another process is inside `barrier-block-and-wait` with the same barrier. In this case it does one of three options:

1. If *wait-if-used-p* is non-nil, it calls `barrier-wait` on *barrier* (without any keyword argument) and returns the result.
2. If *errorp* is non-nil, it calls `error`.
3. Otherwise it returns the other process.

Once `barrier-block-and-wait` has successfully marked *barrier* as used, it changes its count to *t* as if by calling `(barrier-change-count barrier t)`, which will cause other `barrier-wait` calls to wait. If *unlock* is non-nil, it first unblocks all processes that wait on the barrier, so the effect is the same as `(barrier-enable barrier t)`.

It then waits until the arriver count of *barrier* is greater than or equal to *count*, or, if *timeout* is supplied, *timeout* seconds passed. It then returns the number of arrivers.

*result* can be one of three types:

|                         |                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>integer</code>    | The call was successful, and <i>result</i> is the number of arrivers.                                                                                                |
| <code>symbol</code>     | <i>barrier</i> was in use, and <i>wait-if-used-p</i> is non-nil, so <code>barrier-wait</code> was called. <i>result</i> is the result of <code>barrier-wait</code> . |
| <code>mp:process</code> | <i>barrier</i> is in use, and <i>result</i> is the process that uses it.                                                                                             |

## Notes

1. When `barrier-block-and-wait` returns, `barrier` is still set with `t`, that is calls to `barrier-wait` on barrier will wait. Normally the current process will go on to do some operations that require the other processes to wait, and then release them by calling `barrier-disable` or `barrier-enable`.
2. In typical usage, the arriver count is just increased by one by each call to `barrier-wait`, so as long as other processes use only `barrier-wait` (or `barrier-block-and-wait` with `wait-if-used-p` non-nil), `barrier-block-and-wait` will return after `count` processes called `barrier-wait` and are waiting. That is the intended purpose of `barrier-block-and-wait`. If other processes call functions that manipulate the arriver count or the count of `barrier` (`barrier-disable`, `barrier-enable`, `barrier-unblock`, `barrier-change-count`), then `barrier-block-and-wait` will "get confused", in the sense that while its behavior is still well-defined, it is not intuitive.
3. With the default keyword values (not counting `timeout`), `barrier-block-and-wait` is useful for controlling a fixed set of processes by another "master" process. The processes in the set need to call `barrier-wait` at appropriate points. When the "master" process wants to stop them for a while, it calls `barrier-block-and-wait`. When it wants to restart them, it calls `barrier-disable`.
4. A non-nil value of `wait-if-used-p` is useful when any member of a group of processes may decide that it needs to stop all the other processes in the group. In this case, this process calls `barrier-block-and-wait` with `wait-if-used-p` non-nil (and count the number of processes in the group minus one). If two of the processes happen to call it at the same time, one will get the barrier, and the other process will have to wait.

5. The effect of `barrier-block-and-wait` can be approximated by using `barrier-change-count` followed by normal `process-wait` that checks the arrivers count in the wait function. `barrier-block-and-wait` has two advantages:
  - a) It checks against more than one process trying to do it at the same time.
  - b) `barrier-block-and-wait` will wake up immediately when the arriver count reaches the right number. `process-wait` will wake up only when the scheduler checks the wait function and wakes it up.

|-------------|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     |                                                | Changes the count of a <code>barrier</code> .                                                                                                 |
| Package     |                                                | <code>mp</code>                                                                                                                               |
| Signature   |                                                | <code>barrier-change-count barrier new-count =&gt; result</code>                                                                              |
| Arguments   | <code>barrier</code><br><code>new-count</code> | A <code>barrier</code> .<br>A positive fixnum, or <code>t</code> meaning <code>most-positive-fixnum</code> .                                  |
| Values      | <code>result</code>                            | A boolean.                                                                                                                                    |
| Description |                                                | The function <code>barrier-change-count</code> changes the count of the <code>barrier</code> <code>barrier</code> to <code>new-count</code> . |

If *barrier* is enabled and the arriver count is less than *new-count*, this just sets the count of *barrier* to *new-count* and returns *t*. Otherwise, it calls

```
(barrier-unblock barrier :reset-count new-count)
```

and returns *nil*.

## barrier-count

## *Function*

Summary      Returns the current count of a **barrier**.

Package      **mp**

Signature      **barrier-count barrier => result**

Arguments      *barrier*      A **barrier**.

Values      *result*      A positive fixnum, or **nil**.

Description      The function **barrier-count** returns the current count of the **barrier** *barrier*, or **nil** if *barrier* is disabled.

Notes      The count value can be changed by **barrier-unblock**, **barrier-enable**, **barrier-disable** or **barrier-change-count**.

| Values      | <b>result</b>                                                                                                                                                                                                                                                                                                                                                                                                                                | One of the keywords <b>:unblocked</b> and <b>:passed-through</b> . |
| Description | <p>The function <b>barrier-pass-through</b> increments the arriver count of the <b>barrier barrier</b>. If the arriver count thereby reaches the count, <b>barrier-pass-through</b> unblocks <b>barrier</b> and returns <b>:unblocked</b>, otherwise it returns <b>:passed-through</b>.</p> <p><b>barrier-pass-through</b> is equivalent to calling <b>barrier-wait</b> with <b>pass-through t</b>. See <b>barrier-wait</b> for details.</p> |                                                                    |

| Description | <p>The function <code>barrier-unblock</code> unblocks the <code>barrier</code> <code>barrier</code>, potentially disabling it, resetting its count or killing the waiting processes.</p> <p>Without keyword arguments, <code>barrier-unblock</code> unblocks <code>barrier</code>, which means that any thread that is waiting on <code>barrier</code> wakes and returns from <code>barrier-wait</code>, and its arriver count is reset to 0.</p> <p>If <code>disable</code> is true, or if <code>disable</code> is not passed and <code>barrier</code> was made with <code>disable-on-unblock</code> true, then <code>barrier-unblock</code> also disables <code>barrier</code>, so any further calls to <code>barrier-wait</code> return <code>nil</code> immediately.</p> <p>If <code>reset-count</code> is non-nil, it must be valid count (a positive fixnum or <code>t</code>), and <code>barrier-unblock</code> sets the count of <code>barrier</code> to this value.</p> <p>If <code>kill-waiting</code> is true, instead of waking up the waiting threads, <code>barrier-unblock</code> kills them (by <code>process-terminate</code>).</p> |

| Description         | <p>The function <b>barrier-wait</b> waits on a barrier until enough threads arrive on <i>barrier</i>. When <b>barrier-wait</b> is called, it "arrives", and when the number of arrivers reaches the count of the barrier (that is, the <i>count</i> argument to <b>make-barrier</b>), <b>barrier-wait</b> returns. Effectively, the last "arriver" unblocks the barrier and wakes up all the other waiting threads.</p> <p><i>timeout</i> is the maximum time to wait in seconds.</p> <p>If <i>pass-through</i> is true, <b>barrier-wait</b> performs the other operations but does not wait.</p> <p><i>discount-on-abort</i> controls whether to change the arrivers count of <i>barrier</i> on an abort (see later).</p> |

*discount-on-timeout* controls whether to change the arrivers count of *barrier* on a timeout (see later).

*disable-on-unblock* controls whether to disable *barrier* when unblocking.

*callback*, if supplied, specifies a callback called before unblocking.

**barrier-wait** first checks whether *barrier* is disabled, and if it is then **barrier-wait** returns `nil` immediately. It then checks the number of arrivers of *barrier*, which is the number of other calls to **barrier-wait** on the same barrier since it was last unblocked or created.

If the number of arrivers is less than the count minus 1, **barrier-wait** increases the number of arrivers by 1, and then waits for *barrier* to be unblocked (unless *pass-through* is true, which causes it to return immediately). If the number of arrivers of *barrier* equals its count minus 1, then **barrier-wait** unblocks *barrier* (as described below) and returns `:unblocked`.

*discount-on-abort*, *discount-on-timeout*, *disable-on-unblock* and *callback* allow you to control how **barrier-wait** waits and also how *barrier* is unblocking. For each of these, the effective value is either that supplied to **barrier-wait**, or if it was not supplied to **barrier-wait**, the value in *barrier* itself (see **make-barrier**).

*timeout* can be used to limit the time that **barrier-wait** waits. It is either a number of seconds or `nil` (the default), meaning wait forever. If **barrier-wait** times out, it returns `:timeout`. By default it does not change the number of arrivers after a timeout, so the call is still counted as an "arrival", but this can be changed by using *discount-on-timeout*. If *discount-on-timeout* is true then **barrier-wait** decrements the arrivers count after a timeout, so the call has no overall effect on the arrivers count.

If `barrier-wait` is aborted while it waits (for example by `process-terminate` or throwing using `process-interrupt`), it does not change the arrivers count by default, so the call still counts as an arrival, but this can be changed by using `discount-on-abort`. If `discount-on-abort` is true, then `barrier-wait` decrements the arrivers count on aborting, so the call has no overall effect on the arrivers count.

If `barrier-wait` would have waited but `pass-through` is true, it returns the symbol `:passed-through` instead of waiting. Hence a call to `barrier-wait` with a true value of `pass-through` has the effect of incrementing the arriver count, and unblocking other waiters if needed, but never itself waiting.

Unblocking a barrier: when the number of arrivers at `barrier` equals its count minus 1, `barrier-wait` "unblocks the barrier". This involves the following steps:

1. If `callback` is non-nil, it is called with `barrier` while holding an internal lock in the barrier. See the comment in `make-barrier`. If `callback` aborts, nothing will have been changed in `barrier` (including no change to the number of arrivers).
2. `barrier` is marked as unblocked for the currently waiting threads.
3. The number of arrivers in `barrier` is reset to 0. Unless the next step disables `barrier`, this means that any subsequent call to `barrier-wait` will wait, as if `barrier` had just been created.
4. If `disable-on-unblock` is true, `barrier-wait` then disables `barrier`. Until it is re-enabled, any other call to `barrier-wait` will return immediately.
5. All the threads waiting on `barrier` are woken.
6. The symbol `:unblocked` is returned.

The possible values of `result` occur in these circumstances:

|                              |                                                                              |
|------------------------------|------------------------------------------------------------------------------|
| <code>t</code>               | The current process waited and some other process unblocked <i>barrier</i> . |
| <code>:unblocked</code>      | The current process unblocked <i>barrier</i> .                               |
| <code>:timeout</code>        | The wait timed out.                                                          |
| <code>:passed-through</code> | The current process did not wait because <i>pass-through</i> is true.        |
| <code>nil</code>             | <i>barrier</i> is disabled.                                                  |

## condition-variable

## System Class

Summary A class of objects for synchronizing processes.

Package `mp`

Superclasses `t`

Description Instances of the system class `condition-variable` are used for synchronizing processes. They are made by `make-condition-variable`.

See also [make-condition-variable](#)  
[condition-variable-wait](#)

## condition-variable-broadcast

## Function

Summary Wakes all threads currently waiting on a given `condition-variable`.

Package `mp`

Signature `condition-variable-broadcast condvar => signaledp`

Arguments `condvar` A `condition-variable`.

Values `signaledp` A generalized boolean.

Description The function `condition-variable-broadcast` wakes all threads currently waiting on the `condition-variable` `condvar`. In most uses of condition variables, the caller should

be holding the `lock` that the waiter used when calling `condition-variable-wait` for `condvar`, but this is not required. When using the `lock`, you may prefer to use `lock-and-condition-variable-broadcast`.

The return value `signaledp` is non-nil if some processes were signaled, or `nil` if there were no processes waiting.

## condition-variable-signal *Function*

Summary      Wakes one thread waiting on a given `condition-variable`.

Package      `mp`

Signature      `condition-variable-signal condvar => signaledp`

Arguments      `condvar`      A `condition-variable`

Values      `signaledp`      A generalized boolean

Description      The function `condition-variable-signal` wakes exactly one thread waiting on the `condition-variable` `condvar`. In most uses of condition variables, the caller should be holding the `lock` that the waiter used when calling `condition-variable-wait` for `condvar`, but this is not required. When using the `lock`, you may prefer to use `lock-and-condition-variable-signal`.

The return value *signaledp* is non-nil if a process was signaled, or nil if there were no processes waiting.

| Arguments   | <code>condvar</code><br><code>lock</code><br><code>timeout</code><br><code>wait-reason</code> | A <code>condition-variable</code> .<br>A <code>lock</code> .<br>A non-negative <code>real</code> or <code>nil</code> .<br>A string.                                                                                                                                                                                                                      |
| Values      | <code>wakep</code>                                                                            | A generalized boolean.                                                                                                                                                                                                                                                                                                                                   |
| Description |                                                                                               | The function <code>condition-variable-wait</code> waits at most <i>timeout</i> seconds for the <code>condition-variable</code> <i>condvar</i> to be signaled. The <code>lock</code> <i>lock</i> is released while waiting and claimed again before returning. The caller must be holding the <code>lock</code> <i>lock</i> before calling this function. |

The return value `wakep` is non-nil if the signal was received or nil if there was a timeout. If `timeout` is nil, `condition-variable-wait` waits indefinitely.

If `wait-reason` is non-nil, it is used as the `wait-reason` while waiting for the signal.

It is recommended that you use `lock-and-condition-variable-wait` or `simple-lock-and-condition-variable-wait` instead of `condition-variable-wait`. The locking functions make it easier to avoid mistakes, and can be more efficient.

Notes      `timeout` controls how long to wait for the signal: before returning, the function waits to claim `lock`, possibly indefinitely.

| Summary     | Blocks interrupts in the current process.                                                                                                                                                                                                                     |
| Package     | <code>mp</code>                                                                                                                                                                                                                                               |
| Signature   | <code>current-process-block-interrupts =&gt; t</code>                                                                                                                                                                                                         |
| Description | <p>The function <code>current-process-block-interrupts</code> blocks interrupts in the current process.</p> <p>It signals an error if called outside the dynamic scope of <code>allowing-block-interrupts</code> or <code>with-interrupts-blocked</code>.</p> |

Blocking interrupts prevents any interruption of the current process, including `process-interrupt`, `process-kill`, `process-reset`, `process-break` and `process-stop`. These interrupts are all queued and processed once interrupts become unblocked.

Blocking interrupts also blocks interrupts due to POSIX signals. Such interrupts are processed either by another Lisp thread, or once interrupts become unblocked.

The effect of `current-process-block-interrupts` stays in force until the next call to either `current-process-unblock-interrupts` or `current-process-block-interrupts`, or an exit out of the scope of a surrounding `allowing-block-interrupts` or `with-interrupts-blocked`. Inside this range bodies of `allowing-block-interrupts` and `with-interrupts-blocked` have their own state, but they restore it on exit.

| Arguments   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description | <p>The function <code>current-process-kill</code> kills the current process.</p> <p><code>current-process-kill</code> signals an error if it is called when interrupts are blocked, unless it is inside the scope of <code>with-other-threads-disabled</code>, in which case the process is marked as "dying", and actually dies on exit from <code>with-other-threads-disabled</code>.</p> <p>Normally, <code>current-process-kill</code> throws out and does not return. It does execute all surrounding <code>unwind-protect</code> forms.</p> <p>If <code>current-process-kill</code> is called while the process is already doing cleanups, it just returns.</p> |

Notes If you have a process that is broken and repeatedly goes into the debugger and you are not interested in debugging it, then calling `current-process-kill` is the best way of getting rid of it. This is especially useful on non-Cocoa platforms (GTK+ and Windows) when you get an interface that is badly broken.

## **current-process-pause** *Function*

Summary Sleeps for a specified time, but can be woken up.

Package `mp`

Signature `current-process-pause time &optional function &rest args => result`

Arguments `time` A positive number.

`function` A function designator.

`args` Arguments passed to `function`.

Values The keyword `:poked`, or `nil`.

Description The function `current-process-pause` sleeps for `time` seconds, but wakes up if another process did something to wake up the current process (normally this is `process-poke`, but it can also be `process-interrupt`, `process-stop`, `process-unstop` or `process-kill`).

`current-process-pause` is quite similar to `cl:sleep`, but it returns if anything causes the process to wake up, even if the time did not pass.

If `function` is passed just before going to sleep, `current-process-pause` applies `function` to `args`, and if this returns a true value `current-process-pause` returns it immediately.

*function* and *args* are not used otherwise. If another process calls `process-poke` on the current process after setting something that causes *function* to return true, it guarantees that `current-process-pause` will return immediately without sleeping.

If another process woke up the current process, `current-process-pause` returns the keyword `:poked`. If it slept the full time, it returns `nil`.

#### Notes

1. In contrast to `process-wait`, the *function* argument to `current-process-pause` is applied only once, and within the dynamic scope of `current-process-pause`. It therefore does not have any of the restrictions that the *wait-function* of `process-wait` has.
2. The purpose of *function* is to guard against the possibility that another process pokes the current process while it is in the process of going to sleep.
3. There is no way to distinguish between the function returning `:poked` and the process being poked in some way.
4. The pausing does not happen reliably, and it can return `:poked` in a situation when it seems unexpected. For example, if the current process does:

```
(mailbox-read *mailbox*)
...
(current-process-pause)
```

the call to `current-process-pause` may return `poked`, because a process that sent an event to the mailbox tried to poke the current process, and by the time this poke happened the current process is already inside `current-process-pause`. The only guarantees are that `current-process-pause` does not wait when a poke occurred, and that it returns `nil` only when it paused the full time.

Example      Supposed you want to have a process that each minute does some cleanup, but may also be told by other processes to go and do the cleanup. The process be doing:

```
(loop
  (mp:current-process-pause 60 'check-for-need-cleanup)
  (do-cleanup))
```

Another process which wants to provoke a cleanup will do:

```
(setup-cleanup-flag)

(mp:process-poke *cleanup-process*)
```

Note that `check-for-need-cleanup` is passed to `current-process-pause`, because another process may call `process-poke` after `current-process-pause` was called but before it went to sleep. If `check-for-need-cleanup` was not passed, `current-process-pause` would unnecessarily sleep the whole 60 seconds in this case. The same thing could be implemented by `process-wait-with-timeout`, but the implementation above does not require a wait function that can run in another dynamic scope repeatedly at arbitrary times, and it uses much less system resources. It is also easier to debug.

## **current-process-send** *Function*

Summary      Sends an object as an event to the current process.

Package      `mp`

Signature      `current-process-send object`

Arguments      `object`      A Lisp object.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>current-process-send</code> sends <i>object</i> as an event to the current process.</p> <p>This is useful when you want to execute code as an event rather than in the current context. A typical example is when a CAPI callback needs to do something in the current process which is not appropriate to invoke inside the callback.</p> <p>For the object to actually be processed as an event, the current process must process events sometime after <code>current-process-send</code> is called. In the "standard" situation, for example in a process started by CAPI, the object will be processed as an event by calling <code>general-handle-event</code>.</p> |
| See also    | <p><code>process-send</code><br/> <code>general-handle-event</code><br/> “Communication between processes and synchronization”<br/> on page 283</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Signature                                   | <code>current-process-set-terminate-method &amp;key local-terminator<br/>remote-terminator terminate-by-send</code>                                                                                                             |
| Arguments                                   | <p><i>local-terminator</i> A function designator for a function of no arguments.</p> <p><i>remote-terminator</i>A function designator for a function of one argument.</p> <p><i>terminate-by-send</i>A generalized boolean.</p> |
| Description                                 | The function <code>current-process-set-terminate-method</code> sets the Terminate Method of the current process. See <code>pro-</code>                                                                                          |

`cess-run-function` for the meaning of the keyword arguments.

The default value of `terminate-by-send` is `t`. Therefore calling `current-process-set-terminate-method` without arguments sets the Terminate Method to terminate-by-send. Calling `current-process-set-terminate-method` with `terminate-by-send nil` makes the process not have a Terminate Method.

## **debug-other-process** *Function*

Summary      Examine the stack of a process other than the current process.

Package      **mp**

Signature      **debug-other-process** *process*

Arguments      *process*      A process or a string.

Description      The function **debug-other-process** causes the debugger to be entered to examine the stack of another process *process*. The debugger itself continues to run in the current process, and the execution of the other process *process* is not affected. That means that all debugger commands that try to affect execution (for example **:a**, **:c**, **:res**, **:ret**, **:trap**) do not work as in the normal debugger. **:a** is changed instead to exit the debugger.

**Note:** if the other process is still active, the stack will change "under the feet" of the debugger, with unpredictable results. Thus **debug-other-process** is useful only for debugging purposes, or when you already stopped the other process.

The usual way to enter a debugger on another thread is to use **process-break**. However, that would fail if the other process hangs for some reason. In this situation, you can use **debug-other-process** to try to find out why it hangs.

If *process* is a string, the process is found as if by **find-process-from-name**. The list of process names can be found via **ps**.

[process-break](#)  
[ps](#)

\*default-process-priority\* Variable

**Summary** The default priority for processes.

## Package mp

Description The variable **\*default-process-priority\*** contains the default priority for processes.

See also [process-run-function](#)

## **ensure-process-cleanup** *Function*

**Summary** Run forms when a given process terminates.

## Package mp

**Signature**      **ensure-process-cleanup** *cleanup-form* &**key priority force**  
**process** =>

**Signature**      `ensure-process-cleanup cleanup-form &optional process =>`

Arguments      *cleanup-form*      Form to run when process terminates.

*priority* An integer in the inclusive range [-1000000, 1000000].

*force* A boolean.

*process* A `mp:process` object.

Values      None.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description        | <p>The function <code>ensure-process-cleanup</code> ensures that the <i>cleanup-form</i> is present for the process <i>process</i>. When <i>process</i> terminates, its cleanup forms are run. Cleanup forms can be functions of one argument (the <i>process</i>), or lists, in which case the <code>c1:car</code> is applied to the <i>process</i> and the <code>c1:cdr</code> of the list.</p> <p><i>process</i> is the process to watch for termination. By default, this is the value returned by <code>get-current-process</code>.</p> <p><i>priority</i> determines the execution order of the forms. Higher <i>priority</i> means later execution. The system uses values between 700000 and 900000 for cleanups that need to be last, and 0 for other cleanups. The default value of <i>priority</i> is 0.</p> <p><i>force</i> determines what to do if the same cleanup is already registered but with a different <i>priority</i>. When adding cleanup forms, <code>ensure-process-cleanup</code> uses <code>c1:equal</code> to ensure that the form is only added once. If a cleanup already exists with the same priority, <code>ensure-process-cleanup</code> just returns <code>nil</code>, otherwise it acts according to <i>force</i>: if <i>force</i> is <code>nil</code> it invokes an error, but if <i>force</i> is <code>t</code> then <code>ensure-process-cleanup</code> removes the old entry before adding the new entry. The default value of <i>force</i> is <code>nil</code>.</p> <p>When <code>ensure-processes-cleanup</code> is called on a foreign thread, that is a thread that was not created by LispWorks, the cleanups are executed after the outermost foreign-callable returns and before return to the foreign code that called it (that is when no Lisp frames remain on the stack).</p> |
| Compatibility note | Before LispWorks 7.1, the cleanups were never executed when <code>ensure-processes-cleanup</code> was called in a foreign thread.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Notes              | <ol style="list-style-type: none"> <li>1. You can test for whether the current process is executing its cleanups with <code>current-process-in-cleanup-p</code>.</li> <li>2. For compatibility with LispWorks 6.1 and earlier versions, <code>ensure-process-cleanup</code> can also be called like this:</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

```
(ensure-process-cleanup cleanup-form process)
```

Such calls are still allowed, for backwards compatibility, however please update your programs to call it like this:

```
(ensure-process-cleanup cleanup-form
                      :priority priority
                      :force force
                      :process process)
```

**Example** A process calls `add-process-dependent` each time a dependent object is added to a process. When the process terminates, `inform-dependent-of-dead-process` is called on all dependent objects.

```
(defun add-process-dependent (dependent)
  (mp:ensure-process-cleanup
   ` (delete-process-dependent ,dependent)))
```

  

```
(defun delete-process-dependent (process dependent)
  (inform-dependent-of-dead-process dependent process))
```

`process-terminate`

## find-process-from-name *Function*

**Summary** Finds a process from its name.

**Package** `mp`

**Signature** `find-process-from-name process-name => result`

**Arguments** `process-name` A string.

**Values** `result` A `mp:process`, or `nil`.

**Description** The function `find-process-from-name` returns the process with the name `process-name`.

If there is no such process, the function returns `nil`.

**Example**      `CL-USER 16 > (mp:find-process-from-name "Listener 1")  
#<MP:PROCESS Name "Listener 1" Priority 600000 State  
"Running">`

**See also**      `get-process`

## **funcall-async**

## **funcall-async-list**

## *Functions*

**Summary**      Funcall a function asynchronously.

**Package**      `mp`

**Signature**      `funcall-async func &rest args`  
`funcall-async-list func-and-args`

**Arguments**      `func`      A function designator.

`args`      Arguments.

`func-and-args`      A cons.

**Description**      The functions `funcall-async` and `funcall-async-list` call the function `func` with the supplied arguments, that is what `c1:funcall` would do, but asynchronously.

`func-and-args` must be a cons of a function designator and a proper list of arguments.

Multiprocessing must have already started.

These functions do not return a useful value.

**Notes**      1. These functions are effectively lightweight versions of `process-run-function`.

2. On most architectures they are implemented using worker processes, which are named "**Background Execute n**".
3. The maximum number background processes is limited by default to 5 and this is adequate in most cases. However, if you use `funcall-async` and/or `funcall-async-list` often, you may want to increase the limit, by using `set-funcall-async-limit`.
4. The dynamic context of the call to *func* is undefined, and must not be relied upon.
5. The current process should not be accessed inside *func*, except when you want another process to poke the process that runs *func* (this is sometimes useful if *func* calls a wait function). In this case you can call `get-current-process` inside the dynamic scope of *func* to get the process that the other process should poke.
6. `funcall-async` and `funcall-async-list` are intended for functions that finish quickly. If *func* takes a long time, it prevents the background process from executing other async calls, and if all of the background processes become occupied by long-executing functions it will cause other async calls to be delayed until one of the background processes finishes. Thus if you have a long-executing function that you want to run asynchronously, it is better to use `process-run-function` instead, or use your own pool of worker processes.

## general-handle-event

*Generic function*

Summary

"handles" an event, depending on the type of the event object.

|             |                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                                                                                                                                              |
| Signature   | <code>general-handle-event event-object</code>                                                                                                               |
| Arguments   | <code>event-object</code> A Lisp object.                                                                                                                     |
| Description | The generic function <code>general-handle-event</code> "handles" the <code>event-object</code> . What this actually means depends on the type of the object. |

There are system defined methods for these classes:

|                       |                                                      |
|-----------------------|------------------------------------------------------|
| <code>list</code>     | Apply the <code>car</code> to the <code>cdr</code> . |
| <code>function</code> | Call it.                                             |
| <code>symbol</code>   | If fbound call it, otherwise do nothing.             |
| <code>t</code>        | Do nothing.                                          |

You can add methods for your own classes.

`general-handle-event` is used by all functions that process events, for example `wait-processing-events` and `process-all-events`, as well as by internal waiting functions.

|          |                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------|

## get-current-process *Function*

|           |                                                                       |
|-----------|-----------------------------------------------------------------------|
| Summary   | Returns the current Lisp process.                                     |
| Package   | <code>mp</code>                                                       |
| Signature | <code>get-current-process =&gt; result</code>                         |
| Values    | <code>result</code> A <code>mp:process</code> , or <code>nil</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>get-current-process</code> returns the actual process in which it is called. In this respect it differs from <code>*current-process*</code> , which can be bound to another process. In particular, when a process A calls the <i>wait-function</i> of process B, in the <i>wait-function</i> <code>get-current-process</code> returns the process A, but <code>*current-process*</code> is bound to process B.<br><br><code>result</code> is <code>nil</code> if multiprocessing is off. |
| See also    | <code>*current-process*</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## get-process *Function*

|             |                                                                                                                                                |                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns a process corresponding to a supplied designator.                                                                                      |                                                                                                                                                  |
| Package     | <code>mp</code>                                                                                                                                |                                                                                                                                                  |
| Signature   | <code>get-process process-designator =&gt; process</code>                                                                                      |                                                                                                                                                  |
| Arguments   | <code>process-designator</code><br>A <code>mp:process</code> , a string, a stack-group, a function, a symbol or a fixnum.                      |                                                                                                                                                  |
| Values      | <code>process</code>                                                                                                                           | A <code>mp:process</code> .                                                                                                                      |
| Description | The function <code>get-process</code> returns a process according to the supplied <i>process-designator</i> , which is interpreted as follows: |                                                                                                                                                  |
|             | <code>mp:process</code>                                                                                                                        | Return it.                                                                                                                                       |
|             | A string                                                                                                                                       | Find the first process (highest priority) with matching name. Process names are compared by <code>string=</code> .                               |
|             | A stack-group                                                                                                                                  | Return the process of the stack-group.                                                                                                           |
|             | A function                                                                                                                                     | Return the first process that has <i>process-designator</i> as its function (that is, the third argument of <code>process-run-function</code> ). |

|          |                                                                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A symbol | First search for a process using the symbol name as a string, and (if that fails) then search using the symbol as a function.                                                                                                              |
| A fixnum | Find a process for which <i>process-designator</i> is its unique id. The unique id of the current process can be found by<br><code>(sys:current-thread-unique-id)</code> .<br><i>result</i> is <code>nil</code> if multiprocessing is off. |

## get-process-private-property *Function*

Summary Gets the value of a process private property.

Package `mp`

Signature `get-process-private-property indicator process &optional default => result`

Arguments `indicator` A Lisp object.

`process` A process.

`default` A Lisp object.

Values `result` A property value, or *default*.

Description The function `get-process-private-property` gets the value associated with *indicator* in the private properties of the process *process*. If there is no such property, the value *default* is returned.

`get-process-private-property` can be used to read the values of private properties from another process.

The default value of *default* is `nil`.

| Description | The function <b>initialize-multiprocessing</b> initializes multiprocessing, and it does not return until multiprocessing is finished.<br><br><b>initialize-multiprocessing</b> applies the function <b>process-run-function</b> to each of the entries in <b>*initial-processes*</b> to create the initial processes.<br><br>When called with <b>main-process-args</b> , it creates a <b>mp:process</b> object for the initial thread using the arguments in that list as if in the call<br><br><b>(apply 'mp:process-run-function main-process-args)</b><br><br>Supplying <b>main-process-args</b> is useful on Mac OS X if you want to run a pure Cocoa application, since the main thread needs to run the Cocoa event loop. |

It is not necessary to call `initialize-multiprocessing` when the LispWorks IDE is running (that is, after `env:start-environment` has been called), as this automatically starts up multiprocessing.

|          |                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | On Microsoft Windows, Linux, x86/x64 Solaris, FreeBSD, AIX and Mac OS X (using the Cocoa image), the LispWorks IDE starts up by default. |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | A list of the processes the system initializes on startup.                                                                                                                                                                                          |
| Package     | <code>mp</code>                                                                                                                                                                                                                                     |
| Description | <p>The variable <code>*initial-processes*</code> specifies the processes which the system initializes on startup.</p> <p>Each element of the <code>*initial-processes*</code> list is a set of arguments for <code>process-run-function</code>.</p> |
| Example     | To create a listener process as well as your own processes, evaluate this form before saving your image:                                                                                                                                            |
|             | <pre>(push mp::*default-listener-process*       mp::*initial-processes*)</pre>                                                                                                                                                                      |
| See also    | <code>process-run-function</code>                                                                                                                                                                                                                   |

| Summary                        | Informs LispWorks that there are probably not going to be more callbacks from foreign code on the current thread, allowing it to free some data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description                    | <p>The function <code>last-callback-on-thread</code> informs LispWorks that there are probably not going to be more callbacks from foreign code on the current thread (but does not guarantee this).</p> <p><code>last-callback-on-thread</code> must be used in the scope of a call into LispWorks by a foreign callable on a thread that was not created by LispWorks. It informs LispWorks that there are unlikely to be more callbacks into Lisp on the current thread. As a result, LispWorks can cleanup its side.</p> <p>For each thread that was not created by Lisp and on which there was a call into Lisp, LispWorks keeps data on the Lisp side which it uses to make the entry faster. If the thread goes away, this data is not needed and so LispWorks can free it.</p> <p>If another callback occurs on the same thread after a callback that called <code>last-callback-on-thread</code>, LispWorks will have to recreate its side, which takes a little more time, but otherwise it works in the same way. Thus it is possible to call <code>last-callback-on-thread</code> even when it is not guaranteed that there will not be further callbacks on the same thread.</p> <p>Calling <code>last-callback-on-thread</code> on a thread that was created by LispWorks has no effect.</p> |

`last-callback-on-thread` returns `t` when called on a thread that was not created by LispWorks, otherwise it returns `nil`.

**lock***System Class*

Summary     A class of objects for preventing synchronous access.

Package     `mp`

Superclasses     `t`

Description     Instances of the system class `lock` are used to prevent synchronous access to the some object(s) by more than one process at a time. They are made by `make-lock`.

See also     `make-lock`  
`with-lock`

`process-unlock`  
“Locks” on page 277

**lock-and-condition-variable-broadcast***Function*

Summary     Locks, applies a setup function, calls `condition-variable-broadcast` and unlocks.

Package     `mp`

Signature     `lock-and-condition-variable-broadcast lock condvar lock-timeout setup-function &rest args => signaledp`

Arguments     `lock`     A `lock`.  
`condvar`     A `condition-variable`.  
`lock-timeout`     A non-negative `real` or `nil`.  
`setup-function`     A function designator.  
`args`     Arguments to `setup-function`.

Values     `signaledp`     A generalized boolean.

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>lock-and-condition-variable-broadcast</code> locks the lock <code>lock</code>, applies the function <code>setup-function</code> to <code>args</code>, calls <code>condition-variable-broadcast</code> and unlocks <code>lock</code>. <code>lock-and-condition-variable-broadcast</code> makes it easier to avoid mistakes when using a <code>condition-variable</code>.</p> <p><code>lock-and-condition-variable-broadcast</code> performs the equivalent of:</p> <pre>(mp:with-lock (lock nil lock-timeout)   (apply setup-function args)   (mp:condition-variable-broadcast condvar))</pre> <p>It returns the result of the call to <code>condition-variable-broadcast</code>.</p> <p>See <code>condition-variable-broadcast</code> and <code>with-lock</code> for more details.</p> |
| Notes       | <code>setup-function</code> is called with the <code>lock</code> held, so it should do the minimum amount of work and avoid locking other locks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|             | <code>setup-function</code> | A function designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <code>args</code>           | Arguments to <code>setup-function</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values      | <code>signaledp</code>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                             | <p>The function <code>lock-and-condition-variable-signal</code> locks the <code>lock</code> <code>lock</code>, applies <code>setup-function</code> to <code>args</code>, calls <code>condition-variable-signal</code> and unlocks <code>lock</code>. <code>lock-and-condition-variable-signal</code> makes it easier to avoid mistakes when using a <code>condition-variable</code>.</p> <p><code>lock-and-condition-variable-signal</code> performs the equivalent of:</p> <pre>(mp:with-lock (lock nil lock-timeout)   (apply setup-function args)   (mp:condition-variable-signal condvar))</pre> <p>It returns the result of the call to <code>condition-variable-signal</code>.</p> <p>See <code>condition-variable-signal</code> and <code>with-lock</code> for more details.</p> |
| Notes       |                             | <p><code>setup-function</code> is called with <code>lock</code> held, so it should do the minimum amount of work and avoid locking other locks. Normally <code>setup-function</code> should only set the cell that the process(es) that wait(s) on the <code>condition-variable</code> <code>condvar</code> check with the predicate in <code>lock-and-condition-variable-wait</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                              |

| Summary                     | Locks a lock and calls a predicate. If this returns <code>nil</code> , performs the equivalent of <code>condition-variable-wait</code> . Optionally calls a function on return.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |         |                |                       |                  |                        |             |                                 |                        |                                             |                             |                                       |                     |                                                        |                         |                                |                        |                                                        |                            |  |

| Values      | <code>result</code> | See below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description |                     | <p>The function <code>lock-and-condition-variable-wait</code> first locks the lock <code>lock</code> as in <code>with-lock</code>, using <code>lock-wait-reason</code> and <code>lock-timeout</code> for the <code>whostate</code> and <code>timeout</code> arguments of <code>with-lock</code>.</p> <p>It then applies <code>predicate</code> to <code>args</code>. If this call returns <code>nil</code> it performs the equivalent of a call to <code>condition-variable-wait</code>, passing it <code>condvar</code>, <code>lock</code>, <code>condvar-timeout</code> and <code>condvar-wait-reason</code>.</p> <p>If <code>return-function</code> is supplied, it is then applied to <code>return-function-args</code>, and the return value(s) are returned.</p> <p>Before returning, <code>lock</code> is unlocked (in an unwinding form) as in <code>with-lock</code>.</p> <p><code>lock-and-condition-variable-wait</code> returns whatever <code>return-function</code> returns if it is supplied. If <code>return-function</code> is not supplied, <code>lock-and-condition-variable-wait</code> returns the result of <code>predicate</code> if this is not <code>nil</code>, otherwise it returns the result of the equivalent call to <code>condition-variable-wait</code>.</p> |
| Notes       |                     | <ol style="list-style-type: none"><li>1. <code>predicate</code> and <code>return-function</code> are called with <code>lock</code> held, so they should do as little as needed, and avoid locking anything else.</li><li>2. <code>lock-and-condition-variable-wait</code> makes it much easier to avoid mistakes when using <code>condition-variables</code>.</li><li>3. When <code>return-function</code> is not supplied, <code>lock-and-condition-variable-wait</code> does not lock on return, which makes it much more efficient than the equivalent code using <code>with-lock</code> and <code>condition-variable-wait</code>.</li><li>4. When <code>return-function</code> is not needed, <code>simple-lock-and-condition-variable-wait</code> may be more convenient.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

5. All the four signaling functions (`condition-variable-signal`, `condition-variable-broadcast`, `lock-and-condition-variable-signal`, `lock-and-condition-variable-broadcast`) can be used to wake a process waiting in `lock-and-condition-variable-wait`.

| Signature   | <code>lock-locked-p lock =&gt; result</code>                                                                                                                                                                                                                                                                              |            |
| Arguments   | <code>lock</code>                                                                                                                                                                                                                                                                                                         | A lock.    |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                       | A boolean. |
| Description | <p>The function <code>lock-locked-p</code> is the predicate for whether <code>lock</code> is locked. Since that can change at any time, the result is reliable only if you know that the state is not going to change.</p> <p>If <code>lock</code> is a “sharing” lock, this checks whether it is locked exclusively.</p> |            |

| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                       | A boolean.            |
| Description | <p>The function <code>lock-owned-by-current-process-p</code> checks whether the <code>lock</code> <code>lock</code> is locked by the current thread. If this returns <code>nil</code>, then <code>lock</code> is either unlocked or locked by another process.</p> <p>If <code>lock</code> is a "sharing" lock, this also checks whether the current process has an exclusive lock on it. It ignores any shared lock.</p> |                       |

| Signature   | <code>lock-recursively-locked-p lock =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <code>lock</code> A <code>lock</code> .                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      | <code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description | The function <code>lock-recursively-locked-p</code> is the predicate for whether <i>lock</i> is recursively locked. Since that can change at any time, the result is reliable only if you know that the state is not going to change. For the definition of recursive locking, see the <code>make-lock</code> argument <i>recursivep</i> .<br><br>If <i>lock</i> is a “sharing” lock, <code>lock-recursively-locked-p</code> checks whether it is locked exclusively. |

## **lock-name** *Function*

Summary     Returns the name of a **lock**.

Package     **mp**

Signature    **lock-name lock => name**

Arguments    **lock**        A **lock**.

Values        **name**        A string.

Description    The function **lock-name** returns the name of *lock*, which was either passed as the *name* argument to **make-lock** or defaulted.

Example     

```
(let ((lock (mp:make-lock :name "my lock")))
  (mp:lock-name lock))
=> "my lock"
```

                “Locks” on page 277

## **lock-owner** *Function*

Summary     Returns the owner of a **lock**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Arguments   | <code>lock</code> A <code>lock</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <code>result</code> A process, <code>t</code> or <code>:unknown</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The function <code>lock-owner</code> returns the process that currently owns <code>lock</code>, or <code>nil</code>.</p> <p>If <code>lock</code> is a "sharing" <code>lock</code> then <code>lock-owner</code> checks whether it is locked exclusively (see <code>lock-owned-by-current-process-p</code>).</p> <p>If <code>lock</code> is locked then <code>result</code> is normally the process that locked it. If <code>lock</code> was locked while multiprocessing was not running then <code>result</code> is <code>t</code>. Also, if <code>lock</code> was locked by an unknown process (for example, the process is killed while holding <code>lock</code>) then <code>result</code> is <code>:unknown</code>.</p> <p><code>result</code> is <code>nil</code> if <code>lock</code> is not locked.</p> |
| Example     | <pre>CL-USER 1 &gt; (let ((lock (mp:make-lock :name                                          "my lock")))                   (mp:lock-owner lock)) NIL  CL-USER 2 &gt; (let ((lock (mp:make-lock :name                                          "my lock")))                   (mp:with-lock (lock)                     (mp:lock-owner lock))) #&lt;MP:PROCESS Name "CAPI Execution Listener 1" Priority 0 State "Running"&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                               |

| Description  | Instances of the system class <code>mailbox</code> are used to communicate between processes. The communication is done by "sending" objects (any Lisp object) to a mailbox, and "reading" these objects from the mailbox. The objects will be read in the order in which they were sent. Sending is done by <code>mailbox-send</code> or <code>mailbox-send-limited</code> . Reading is done by <code>mailbox-wait-for-event</code> , <code>mailbox-wait</code> or <code>mailbox-read</code> . All mailbox access functions are thread-safe. You create a mailbox by using <code>make-mailbox</code> . You can also obtain the mailbox of a process by <code>process-mailbox</code> . |

| Arguments                          | <b><code>mailbox</code></b> A <b><code>mailbox</code></b>                                                                                                                                                                                                                                                                                                                                                                                    |
| Values                             | <b><code>bool</code></b> A boolean                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description                        | The function <b><code>mailbox-full-p</code></b> returns true if <i>mailbox</i> is empty and false otherwise.                                                                                                                                                                                                                                                                                                                                 |
| Notes                              | Because of multiprocessing, it cannot be guaranteed that a subsequent call to <b><code>mailbox-send</code></b> will work without expansion even if <b><code>mailbox-full-p</code></b> returns false. <b><code>mailbox-full-p</code></b> is intended to be used as a wait-function (or inside a wait-function), and once it returns false you should use <b><code>mailbox-send-limited</code></b> to actually send and check what it returns. |

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>mailbox-peek</code> returns the first object in the mailbox without removing it. If the mailbox is empty, <code>nil</code> is returned.</p> <p>If the mailbox <i>mailbox</i> is not empty, the function <code>mailbox-peek</code> returns the first object in the mailbox without removing it. The second returned value <i>value-p</i> is <code>t</code>.</p> <p>If <i>mailbox</i> is empty, both return values <i>result</i> and <i>value-p</i> are <code>nil</code>.</p>                                                        |
| Notes       | <ol style="list-style-type: none"> <li>1. Since another process may modify the mailbox at any point, the result is not necessarily the next object that the next call to <code>mailbox-read</code> will read, unless no other process is reading from the mailbox.</li> <li>2. <code>mailbox-peek</code> needs to lock the mailbox, which means it is significantly slower than <code>mailbox-not-empty-p</code>, and also may affect other processes. In most cases, <code>mailbox-not-empty-p</code> is sufficient and hence is preferable.</li> </ol> |

| Description | <p>The function <code>mailbox-read</code> returns the next object from the mailbox <i>mailbox</i>, or <code>nil</code>.</p> <p>If <i>mailbox</i> is empty and <i>timeout</i> is <code>nil</code>, then <code>mailbox-read</code> blocks until an object is placed in <i>mailbox</i>. If <i>mailbox</i> is empty and <i>timeout</i> is a non-negative <code>real</code>, then <code>mailbox-read</code> blocks until an object is placed in <i>mailbox</i> or <i>timeout</i> seconds have passed. If the timeout occurs, then <code>mailbox-read</code> returns <code>nil</code> as the first value and also <i>flag</i> is <code>nil</code>. If an object is actually read from the mailbox, then <i>flag</i> is <code>t</code>.</p> <p>The <i>wait-reason</i> argument defaults to "Waiting for message in #&lt;Mailbox...&gt;" and will be the value returned by <code>process-whostate</code> while <code>mailbox-read</code> is blocking.</p> <p>The default value of <i>timeout</i> is <code>nil</code>.</p> |                                                        |

|             | <code>object</code>                            | An object.                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |                                                | <p>The function <code>mailbox-send</code> sends <code>object</code> to <code>mailbox</code>. The object is queued in the mailbox for retrieval by the reader.</p> <p>When objects are read from from the mailbox (using <code>mailbox-read</code> or higher level functions such as <code>mailbox-wait-for-event</code>), they are read in the order in which they were added to the mailbox.</p> |
| Notes       |                                                | If <code>mailbox</code> is full, <code>mailbox-send</code> expands it. In situations where the mailbox can grow too much, you can use <code>mailbox-send-limited</code> instead.                                                                                                                                                                                                                  |

| Values      | <b>success</b>                                                                                                 | A boolean.                                                                                                                                                              |
| Description |                                                                                                                | The function <b>mailbox-send-limited</b> adds <i>object</i> to <i>mailbox</i> in the same way as <b>mailbox-send</b> , except in the case where <i>mailbox</i> is full. |

If `mailbox` is full and has a size less than `limit` then `mailbox` is enlarged to have a size that is at most `limit` and `object` is added to `mailbox`.

Otherwise, if `mailbox` is full and has a size not less than `limit` then `mailbox-send-limited` waits until `mailbox` becomes not full before adding `object`. While waiting, `mailbox-send-limited` will return without adding `object` to `mailbox` if `timeout` is non-nil and `timeout` seconds has elapsed or if `wait-function` is non-nil and applying `wait-function` to `args` returns true.

`wait-reason` is used as the wait-reason while waiting.

`success` is true if the object was added to the mailbox and false otherwise (`timeout` reached or `wait-function` returned true).

## Notes

`mailbox-send-limited` only prevents the mailbox from expanding to more than `limit`: if it is already bigger than the limit, and there is still a space in it, `mailbox-send-limited` add the object to the mailbox even if that means that the mailbox has more objects than `limit`. As long as all of the sending calls on a `mailbox` are limited, the mailbox may grow until it reaches the largest limit, and if it was made with the `:size` argument equal or larger than the largest limit, it will never grow. However, if `mailbox-send` is called then that may enlarge it.

`process-send` uses `mailbox-send`, so may expand the mailbox too. It also has a `limit` argument.

`mailbox-send-limited` waits like `process-wait-with-timeout`. As a result, there may be some latency between the time the mailbox becomes non-full and the waiting returns, because it depends on the scheduler. The `wait-reason`, `timeout`, `wait-function` and `args` are analogous to the arguments of `process-wait-with-timeout`. `wait-function` is applied within the wait-function that `mailbox-send-limited` uses, so has the same limitations as the wait-function of `process-wait-with-timeout`.

When *timeout* is 0 **mailbox-send-limited** never waits.

## **mailbox-size**

## *Function*

Summary      Returns the size of a **mailbox**.

Package      **mp**

Signature      **mailbox-size** *mailbox* => *size*

Arguments      *mailbox*      A **mailbox**.

Values      *size*      An non-negative integer.

Description      The function **mailbox-size** returns the size of *mailbox*, which is the number of objects that can be added without it growing.

**mailbox-send** automatically expands the mailbox indefinitely when it is full, but **mailbox-send-limited** and **process-send** will expand it up to some specified *limit*.

| Description         | <p>The function <code>mailbox-wait</code> waits until there is an object in the mailbox <i>mailbox</i>. If <i>mailbox</i> is empty and <i>timeout</i> is <code>nil</code>, then <code>mailbox-wait</code> blocks until an object is placed in <i>mailbox</i>. If <i>mailbox</i> is empty and <i>timeout</i> is a non-negative <code>real</code>, then <code>mailbox-wait</code> blocks until an object is placed in <i>mailbox</i> or <i>timeout</i> seconds have passed. If there is no object after <i>timeout</i> seconds, then <code>mailbox-wait</code> returns <code>nil</code>. Once there is an object in <i>mailbox</i>, <code>mailbox-wait</code> returns <code>t</code>.</p> <p>Note that <code>mailbox-wait</code> does not remove the object from the <i>mailbox</i>, in contrast to <code>mailbox-read</code> which does.</p> <p>Note that if there are multiple processes reading from <i>mailbox</i>, another process may read the object from it, so the <i>result</i> of <code>mailbox-wait</code> is reliable only if you know that the current process is the only process that may read from the mailbox.</p> <p>The <i>wait-reason</i> argument defaults to a string</p> <pre>"Waiting for message in #&lt;Mailbox...&gt;"</pre> <p>and will be the value returned by <code>process-whostate</code> while <code>mailbox-wait</code> is blocking.</p> |                |                          |                    |                                |                |                                                        |

The default value of *timeout* is `nil`.

`mailbox-wait` arranges for immediate notification when an object is placed in *mailbox* (unless other processes were waiting too, in which case one of the processes is notified immediately). It is therefore better than using `process-wait` with `mailbox-not-empty-p` because it does not rely on the scheduler to wake it up. It is also less expensive because does not add work to the scheduler.

## mailbox-wait-for-event *Function*

Summary      Waits for an event in a "windowing friendly" way.

Package      `mp`

Signature      `mailbox-wait-for-event mailbox &key wait-reason wait-function process-other-messages-p no-hang-p stop-at-user-operation-p => result`

|           |                                       |                                |
|-----------|---------------------------------------|--------------------------------|
| Arguments | <code>mailbox</code>                  | A <code>mailbox</code> .       |
|           | <code>wait-reason</code>              | A string or <code>nil</code> . |
|           | <code>wait-function</code>            | A function designator.         |
|           | <code>process-other-messages-p</code> | A generalized boolean.         |
|           | <code>no-hang-p</code>                | A generalized boolean.         |

*stop-at-user-operation-p*

A generalized boolean.

| Description | <p>The function <code>mailbox-wait-for-event</code> waits for an event in a <code>mailbox</code> in a "windowing friendly" way. It reads an event from the mailbox <i>mailbox</i>. If there is no event in the mailbox, it waits for an event (unless <i>no-hang-p</i> is true).</p> <p>The value <i>result</i> is any object that was put in the mailbox, or <code>nil</code> if the mailbox is empty, possibly after waiting.</p> <p><code>mailbox-wait-for-event</code> is the appropriate way to wait for an event in a <code>mailbox</code> in an application with a graphical user interface, because it interacts correctly with the windowing system. Most importantly, on Microsoft Windows, when <i>process-other-messages-p</i> is true it processes Windows messages while it is waiting. The default value of <i>process-other-messages-p</i> is <code>t</code>.</p> <p>If <i>wait-function</i> is non-<code>nil</code>, then is it called as a Process Wait function (see “Generic Process Wait functions” on page 281) with the mailbox <i>mailbox</i> as its argument while waiting for an event. If the call returns true before any events arrive, then <code>mailbox-wait-for-event</code> will return <code>nil</code>.</p> <p><i>wait-reason</i> is used as the wait reason if it needs to wait. The default value of <i>wait-reason</i> is "Waiting for an event".</p> <p><i>process-other-messages-p</i> controls processing of other messages. On Microsoft Windows this means Windows messages. On other platforms it has no effect.</p> <p><i>no-hang-p</i> controls whether <code>mailbox-wait-for-event</code> should really wait. If <i>no-hang-p</i> is true and there is no event, it returns immediately except on Microsoft Windows, where it may first process all Windows messages (depending on the value of <i>process-other-messages-p</i>). The default value of <i>no-hang-p</i> is <code>nil</code>.</p> |                                |

`stop-at-user-operation-p` on Microsoft Windows causes `mailbox-wait-for-event` to return if it received a user operation message (meaning keyboard or mouse input). It has no effect on other platforms. The default value of `stop-at-user-operation-p` is `nil`.

If `mailbox-wait-for-event` is called when not Lisp is not multiprocessing, it returns immediately. The return value is an event or `nil`.

## \*main-process\*

### Variable

Summary      The process associated with the main thread.

Package      `mp`

Description    This special variable contains the process associated with the main thread of the application. On Mac OS X with the Cocoa GUI, this is the thread that runs the Cocoa event loop. On other platforms, this variable is always `nil`.

## make-barrier

### Function

Summary    Returns a new `barrier`.

Package    `mp`

Signature    `make-barrier count &key discount-on-abort discount-on-timeout  
callback disable-on-unblock name => barrier`

| Arguments   | <i>count</i>   | A positive fixnum or <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | <i>name</i>    | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Values      | <i>barrier</i> | A <code>barrier</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                | <p>The function <code>make-barrier</code> returns a new <code>barrier</code> with count <i>count</i>.</p> <p><i>count</i> can be <code>t</code>, which is interpreted as <code>most-positive-fixnum</code>.</p> <p><code>barrier</code> has the name <i>name</i>, which is useful for debugging but is not used otherwise. If <i>name</i> is omitted, then a default name is generated that is unique among all such default names.</p> <p><i>discount-on-timeout</i> and <i>discount-on-abort</i> determine the default behavior when a thread times out or aborts while in the function <code>barrier-wait</code>. See the documentation for <code>barrier-wait</code>.</p> <p>If <code>disable-on-unblock</code> is true, then <code>barrier-wait</code> will disable <code>barrier</code> by default when it unblocks it. See <code>disable-on-unblock</code> in the documentation for <code>barrier-wait</code>.</p> <p><code>callback</code> is called by <code>barrier-wait</code> just before it unblocks <code>barrier</code>. It is called with a single argument, <code>barrier</code>, while holding an internal lock in <code>barrier</code> that will prevent other operations on <code>barrier</code> from running. The callback is guaranteed to happen before <code>barrier-wait</code> allows any of the other threads to continue.</p> |
| Notes       |                | <p>Because the callback is called inside a lock, you should ensure that it is relatively short to prevent congestion if another thread tries to access <code>barrier</code>. Allocating a few objects is reasonable. If there is a more expensive operation that has to be done by only one of the threads, it can be done by the thread that returned <code>:unblocked</code> from <code>barrier-wait</code>. The advantage of using the callback is that it is called before any of the waiting threads pass the barrier.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Arguments   | <b>name</b> A string naming the <b>condition-variable</b> .                                                                                                                                                                                                                                                                                                                                                           |  |
| Values      | <b>condvar</b> A <b>condition-variable</b> .                                                                                                                                                                                                                                                                                                                                                                          |  |
| Description | The function <b>make-condition-variable</b> makes a <b>condition-variable</b> for use with <b>condition-variable-wait</b> , <b>condition-variable-signal</b> and <b>condition-variable-broadcast</b> .<br><br><b>name</b> is used when printing the <b>condition-variable</b> , and is useful for debugging. If <b>name</b> is omitted, then a default name is generated that is unique among all such default names. |  |

| Description | The function <b>make-lock</b> creates a <b>lock</b> . See “Locks” on page 277 for a general description of locks.<br><br><i>name</i> names <i>lock</i> and can be queried with <b>lock-name</b> . The default value of <i>name</i> is "Anon".<br><br><i>important-p</i> controls whether <i>lock</i> is automatically freed when the holder process finishes. When <i>important-p</i> is true, the system notes that <i>lock</i> is important, and automatically frees it when the holder process finishes. <i>important-p</i> should be <b>nil</b> for locks which are managed completely by the application, as it is wasteful to record all locks in a global list if there is no need to free them automatically. This might be appropriate when two processes sharing a lock must both be running for the system to be consistent. If one process dies, then the other one kills itself. Thus the system does not need to worry about |                                                                                                                   |

freeing the lock because no process could be waiting on it forever after the first process dies. The default value of *important-p* is `nil`.

*safep* controls whether *lock* is safe. A safe lock gives an error if `process-unlock` is called on it when it is not locked by the current process, and potentially in other 'dangerous' circumstances. An unsafe lock does not signal these errors. The default value of *safep* is `t`.

*recursivep*, when true, allows *lock* to be locked recursively. Trying to lock a lock that is already locked by the current thread just increments its lock count. If *lock* is created with *recursivep nil* then trying to lock again causes an error. This is useful for debugging code where *lock* is never expected to be claimed recursively. The default value of *recursivep* is `t`.

*sharing*, when true, causes *lock* to be a "sharing" lock object, which supports sharing and exclusive locking. At any given time, a sharing lock may be free, or it may be locked for sharing by any number of threads or locked for exclusive use by a single thread. Sharing locks are handled by different functions and methods from non-sharing locks.

#### Example

```
CL-USER 3 > (setq *my-lock* (mp:make-lock
   :name "my-lock"))
#<MP:LOCK "my-lock" Unlocked 2008CAC7>

CL-USER 4 > (mp:process-lock *my-lock*)
T

CL-USER 5 > *my-lock*
#<MP:LOCK "my-lock" Locked once by "CAPI Execution
Listener 1" 2008CAC7>

CL-USER 6 > (mp:process-lock *my-lock*)
T

CL-USER 7 > *my-lock*
#<MP:LOCK "my-lock" Locked 2 times by "CAPI Execution
Listener 1" 2008CAC7>
```

| Description | <p>The function <b>make-mailbox</b> returns a new mailbox. <b>size</b> specifies the initial size of the mailbox <i>mailbox</i>. The reader process is set to <b>nil</b>.</p> <p><i>name</i> does not affect the functionality of <i>mailbox</i>, but can be very useful for debugging. It appears in the printed representation of <i>mailbox</i>, and also in the <b>process-whostate</b> of any process that waits for <i>mailbox</i> (using <b>mailbox-read</b>).</p> |                  |

| Values           | <i>timer</i> A timer                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |                    |                 |            |                  |                                       |
| Description      | <p>The function <code>make-named-timer</code> creates and returns a named timer. The first argument is a string or symbol naming the timer. The second argument is a function to be applied to the remaining arguments when the timer expires. Use the function <code>schedule-timer</code> or <code>schedule-timer-relative</code> to set an expiration time.</p> <p>In comparison, the function <code>make-timer</code> creates an unnamed timer.</p> |             |                    |                 |            |                  |                                       |
| Example          | <pre>(setq timer (mp:make-named-timer 'timer-1 'print 10  *standard-output*))</pre> <pre>#&lt;Time Event TIMER-1 : PRINT&gt;</pre>                                                                                                                                                                                                                                                                                                                      |             |                    |                 |            |                  |                                       |

| Description           | The function <code>make-semaphore</code> returns a new <b>semaphore</b> for use with <code>semaphore-acquire</code> and <code>semaphore-release</code> . The unit count is initialized to <i>count</i> , which defaults to 1. If <i>name</i> is supplied, the semaphore will have that name. If <i>name</i> is not supplied, the semaphore will be given a unique anonymous name. |             |            |              |                        |

| Description |                  | <p>The function <code>make-timer</code> creates and returns an unnamed timer. The <i>function</i> argument is a function to be applied to the remaining arguments when the timer expires. Use the function <code>schedule-timer</code> or <code>schedule-timer-relative</code> to set an expiration time.</p> <p>If <i>function</i> returns the keyword <code>:stop</code>, then <i>timer</i> is unscheduled (as if by <code>unschedule-timer</code>). This allows you to schedule a repeating timer (by passing <i>repeat-time</i> to <code>schedule-timer</code>, <code>schedule-timer-relative</code>, <code>schedule-timer-milliseconds</code> or <code>schedule-timer-relative-milliseconds</code>) that unschedules itself when some condition is true. Otherwise the values returned by <i>function</i> are ignored.</p> <p>Note that the function <code>make-named-timer</code> creates a named timer.</p> |
| Example     |                  | <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*)) =&gt; #&lt;Time Event : PRINT&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## map-processes

## *Function*

Summary

Calls a predicate function on processes in turn until a true value is returned.

Package

`mp`

Signature

`map-processes function -> result`

Arguments

`function`

A function taking one argument

Values

`result`

A process or `nil`.

Description

The function `map-processes` calls `function` on processes.

`function` is passed each live process (as determined by `process-alive-p`) in turn as its single argument.

For a process argument `p`, if `function` returns `nil` then `map-processes` continues by calling `function` on another process,

but if function returns true then `map-processes` returns *p* immediately and stops calling *function* (so *function* may not get called on all processes).

| Values      | <code>reasons</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A list of reasons. |
| Description | The function <code>process-arrest-reasons</code> returns a list of the reasons why a Lisp process has stopped. A process is inactive if it has any arrest reasons.<br><br>Use of <code>(setf mp:process-arrest-reasons)</code> is deprecated. You should use <code>process-stop</code> instead. If you set the arrest reasons of the current process, this causes the current process to stop immediately, before returning from <code>mp:process-arrest-reasons</code> (like <code>process-stop</code> ). |                    |

Compatibility notes The immediate stopping behavior of (`setf mp:process-arrest-reasons`) is different from LispWorks 5.0 and previous versions.

`process-stop`

## process-break *Function*

Summary Breaks a Lisp process and enters the debugger.

Package `mp`

Signature `process-break process =>`

Arguments `process` A process.

Values None.

Description The function `process-break` forces the process `process` to break and enter the debugger.

See also `debug-other-process`

## process-continue *Function*

Summary Wakes up a process.

Package `mp`

Signature `process-continue process => nil`

Arguments `process` A `mp:process` object.

**process-exclusive-unlock** *Function*

Summary      Like `process-unlock`, but on a "sharing" lock.

Package      `mp`

Signature      `process-exclusive-unlock sharing-lock`

Arguments      `sharing-lock`      A sharing lock.

Description      The function `process-exclusive-unlock` is the same as `process-unlock` but for a "sharing" lock.

Calls to `process-exclusive-unlock` should be paired with `process-exclusive-lock` calls. In most cases the macro `with-exclusive-lock` the best way to achieve this.

Notes      `process-exclusive-unlock` is guaranteed to successfully unlock `sharing-lock`, but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 278.

| Summary                           | Specifies the variables initially bound in a new process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Package                           | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description                       | This specifies the variables that are initially bound in a Lisp process when that process is created. This variable is an association list of symbols and initial value forms. The initial value forms are processed by a simple evaluation that handles symbols and function call forms, but not special operators. As a special case, if the value form is the same as the symbol and that symbol is unbound, then the symbol will be unbound in the new process.<br><br>When <code>process-run-function</code> is called, it performs the evaluation in the dynamic environment of the call. It is therefore possible to bind <code>*process-initial-bindings*</code> dynami- |

cally around the call, as shown in the examples below, and that is the preferred way of using `*process-initial-bindings*` (rather than setting the global value).

The initial value forms in `*process-initial-bindings*` are also evaluated in outer calls on foreign threads, which are threads that were made by foreign code rather than by Lisp. See “Foreign callbacks on threads not created by Lisp” on page 297 for discussion. Note that in this case, the evaluation occurs in a dynamic environment where the variables in `*process-initial-bindings*` are not bound yet. That is different from calls to `process-run-function`, where all the variables that were in `*process-initial-bindings*` at the time that the calling process was created are already bound.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p>Changing the global value of <code>*process-initial-bindings*</code> affects all new processes in the system, including processes that will be associated with foreign threads. Unless that is what you want, you should not set the global value. When you do set it, you should take care to avoid errors.</p> <p>Errors in the evaluation are signaled in the standard way when they occur due to <code>process-run-function</code>. When LispWorks creates processes for its own use, it just ignores such errors and binds the corresponding variable to <code>nil</code>. When the evaluation is for a foreign thread, the error is signaled as usual, wrapped with a restart that allows you to use <code>nil</code> as the value.</p> |
| Examples | <p>This example shows a typical use with a bound symbol:</p> <pre>(defvar *binding-1* 10)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

```
(let ((mp:*process-initial-bindings*
      (cons '(*binding-1* . 20)
            mp:*process-initial-bindings*)))
  (mp:process-run-function
   "binding-1"
   '()
   #'(lambda (stream)
        (format stream "~&Binding 1 is ~S.~%" *binding-1*))
   *standard-output*)
  (sleep 1))
=>
Binding 1 is 20.
```

This example shows the special case with an unbound symbol:

```
(defvar *binding-2*)

(let ((mp:*process-initial-bindings*
      (cons '(*binding-2* . *binding-2*)
            mp:*process-initial-bindings*)))
  (flet ((check-binding-2 ())
         (mp:process-run-function
          "binding-2"
          '()
          #'(lambda (stream)
              (if (boundp '*binding-2*)
                  (format stream "~&Binding 2 is ~S.~%" *binding-2*)
                  (format stream "~&Binding 2 is
unbound.~%")))
          *standard-output*)
         (sleep 1)))
    (check-binding-2)
    (let ((*binding-2* 123))
      (check-binding-2))))
=>
Binding 2 is unbound.
Binding 2 is 123.
```

## process-internal-server-p

## *Function*

Summary      Tests whether a process is an internal server.

|             |                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                                                                                                                                                          |
| Signature   | <code>process-internal-server-p process =&gt; result</code>                                                                                                              |
| Arguments   | <code>process</code> A <code>mp:process</code> object.                                                                                                                   |
| Values      | <code>result</code> A boolean.                                                                                                                                           |
| Description | The function <code>process-internal-server-p</code> is the predicate for whether a process is marked as "internal server".                                               |
| Notes       | Processes are marked as "internal server" by a true value for <code>:internal-server</code> amongst the <i>keywords</i> in a call to <code>process-run-function</code> . |
| See also    | <code>process-run-function</code><br><code>any-other-process-non-internal-server-p</code>                                                                                |

## **process-interrupt** *Function*

|             |                                                                                                                                                                                                                                         |

| Values      | None.                                                                                                                                                                                                                                   |
| Description | The function <code>process-interrupt</code> causes the Lisp process <code>process</code> to apply <code>function</code> to <code>arguments</code> when it is next resumed. Afterwards the process resumes its normal execution, as long |

as *function* does not throw. A waiting process is temporarily woken up.

**Notes** Interrupts should be used only for simple operations such as setting a variable. Any more complex interrupt *function* is potentially dangerous and should be avoided. The problem is that even simple code like:

```
(let ((message (read-message)))
  (process-message message))
```

may lose the message if an interrupt ends up throwing between the two lines. In addition, the code in the interrupt may be executed while some tree of pointers is in an inconsistent state (while the message is incompletely processed, for example).

**See also** `process-interrupt-list`

## process-interrupt-list *Function*

**Summary** Interrupts a process.

**Package** `mp`

**Signature** `process-interrupt-list process function arguments =>`

**Arguments** `process` A process.

`function` A function to apply on resuming *process*.

`arguments` A list of the arguments to supply to *function*.

**Values** None.

**Description** The function `process-interrupt-list` causes the Lisp process *process* to apply *function* to *arguments* when it is next

resumed. It is just like `process-interrupt` except that the *arguments* are supplied as a list.

See also `process-interrupt`

## `process-join` *Function*

Summary Waits until a specified process dies, or a *timeout* is reached.

Package `mp`

Signature `process-join process &key timeout => flag`

Arguments `process` A process.

`timeout` A non-negative `real` or `nil`.

Values `flag` A boolean.

Description The function `process-join` waits until the process *process* dies, or *timeout* seconds passed.

If the process dies then `process-join` returns `t`. If the timeout passed it returns `nil`.

`process-join` can be used on dead processes, and in this case returns `t` immediately.

The effect of `process-join` is similar to

```
(mp:process-wait-with-timeout
  "Waiting for process to die" timeout
  #'(lambda (x)
      (not (mp:process-alive-p x))) process)
```

but the call above may not return until the next time the scheduler runs, possibly causing a delay. In contrast `process-join` returns immediately when the process dies.

| Description         | The function <code>process-kill</code> kills the specified Lisp process.<br><br><code>process-kill</code> is deprecated. Use <code>process-terminate</code> instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Notes               | <ol style="list-style-type: none"> <li>1. <code>process-kill</code> kills the process by sending it an interrupt with <code>current-process-kill</code>, which will throw out of whatever it is doing. That means that any code that is executing without interrupts blocked may abort in the middle. It is wise in general to block interrupts around all sensitive places, so that <code>process-kill</code> may kill the process in a non-sensitive place.</li> <li>2. If <code>process-kill</code> is called while the process is in a no-interrupt context, the killing will actually happen when the process exits that no-interrupt context.</li> <li>3. If the killing happens inside the cleanup forms of <code>unwind-protect</code>, it may terminate a cleanup in the middle. It is possible to protect against this by doing all cleanups with interrupts disallowed, but that is not easy. Thus <code>process-kill</code> may be problematic, and should be avoided when possible. Whenever possible, make your processes check some flag that can be set by other threads and exit when the flag is set to some value.</li> </ol> |

| Description | <p>The function <code>process-lock</code> attempts to lock <code>lock</code> and returns <code>t</code> if successful, or <code>nil</code> if timed out.</p> <p>If <code>lock</code> is already locked and its owner is the value of <code>*current-process*</code>, then the value of <code>recursivep</code> in the <code>lock</code> (see <code>make-lock</code>) controls what happens. If <code>recursivep</code> is true, then <code>lock</code> remains locked and an internal count is incremented (this is called recursive locking). Otherwise, an error is signaled.</p> <p>The Lisp process sleeps until the lock can be locked or the timeout period specified by <code>timeout</code> expires.</p> <p><code>result</code> is <code>t</code> if <code>lock</code> was successfully locked, and <code>nil</code> otherwise.</p> |                                                                                                                                                                                                                                      |

|          |                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>process-lock</code> is guaranteed to return if it locked process, but may throw before locking, as described in “Guarantees and limitations when locking and unlocking” on page 278. |
| Example  | <code>(process-lock *my-lock* "waiting to lock" 10)</code>                                                                                                                                 |
| See also | <code>make-lock</code><br><code>process-exclusive-lock</code><br><code>process-unlock</code><br><code>with-lock</code><br>“Locks” on page 277                                              |

## process-mailbox *Function*

|             |                                                                                                                               |                                              |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Summary     | Accesses the mailbox associated with a process.                                                                               |                                              |
| Package     | <code>mp</code>                                                                                                               |                                              |
| Signature   | <code>process-mailbox process =&gt; result</code><br><code>(setf process-mailbox) result process =&gt; result</code>          |                                              |
| Arguments   | <code>process</code>                                                                                                          | A process.                                   |
| Values      | <code>result</code>                                                                                                           | A <code>mailbox</code> or <code>nil</code> . |
| Description | <code>process-mailbox</code> is an accessor function which returns or sets the mailbox associated with <code>process</code> . |                                              |
| Example     | <code>(setf (mp:process-mailbox mp:*current-process*)</code><br><code>(mp:make-mailbox))</code>                               |                                              |

## process-name *Function*

|         |                                          |
|---------|------------------------------------------|
| Summary | Returns the name of a specified process. |
|---------|------------------------------------------|

|             |                                              |                                                                                        |
|-------------|----------------------------------------------|----------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                              |                                                                                        |
| Signature   | <code>process-name process =&gt; name</code> |                                                                                        |
| Arguments   | <code>process</code>                         | A process.                                                                             |
| Values      | <code>name</code>                            | The name of the process specified by <code>process</code> .                            |
| Description |                                              | The function <code>process-name</code> returns the name of the specified Lisp process. |

## **process-p** *Function*

|             |                                          |                                                                                                                                 |
|-------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The predicate for processes.             |                                                                                                                                 |
| Package     | <code>mp</code>                          |                                                                                                                                 |
| Signature   | <code>process-p object =&gt; bool</code> |                                                                                                                                 |
| Arguments   | <code>object</code>                      | Any object                                                                                                                      |
| Values      | <code>bool</code>                        | A generalized boolean.                                                                                                          |
| Description |                                          | The function <code>process-p</code> returns <code>t</code> if <code>object</code> is a process, and <code>nil</code> otherwise. |

## **process-plist** *Function*

|           |                                                                           |  |
|-----------|---------------------------------------------------------------------------|--|
| Summary   | Returns the plist associated with a process. This function is deprecated. |  |
| Package   | <code>mp</code>                                                           |  |
| Signature | <code>process-plist process =&gt; plist</code>                            |  |

|             |                                                                                                                                                                                                                                                                                                   |           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Arguments   | <i>process</i>                                                                                                                                                                                                                                                                                    | A process |
| Values      | <i>plist</i>                                                                                                                                                                                                                                                                                      | A plist   |
| Description | The function <code>process-plist</code> returns the plist associated with <i>process</i> .                                                                                                                                                                                                        |           |
| Notes       | It is not possible to manipulate the plist in a thread-safe manner, and <code>process-plist</code> may interact badly with other users of the plist, hence <code>process-plist</code> is deprecated. Use instead <code>process-property</code> and <code>get-process-private-property</code> etc. |           |

## process-poke *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Summary     | Makes a waiting process call its wait function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |

| Description | If the process <i>process</i> is waiting, the function <code>process-poke</code> causes it to run its <i>wait-function</i> as soon as possible, and if the wait function returns true, the process returns from the waiting function.<br><br><code>process-poke</code> is especially useful when using the <code>process-wait-local-*</code> functions. With <code>process-wait-local</code> and <code>process-wait-local-with-timeout</code> , it is the only way to ensure that the waiting process checks the wait function. The other functions also check periodically, but <code>process-poke</code> is still useful to make them wake up immediately. |            |

With a non-local wait function (that is, in `process-wait` and `process-wait-with-timeout`), `process-poke` is useful in SMP LispWorks to ensure that the process wakes and checks its *wait-function* immediately. `process-poke` has no effect on non-SMP LispWorks for `process-wait` and `process-wait-with-timeout`.

You can also use `process-poke` to wake up a process that waits using `current-process-pause`.

`process-poke` returns `t` if it actually poked the process or `nil` otherwise (when the process is not waiting or is stopped).

The process wait functions are designed to call the *wait-function* just before going to sleep, in a way that guards against a race condition between `process-poke` and the waiting function. In particular, they ensure that if a process goes to wait with a *wait-function* that checks some value, and another process sets this value and calls `process-poke` on the first process, the first either will check the value before going to sleep, or wake up and check the value. The first process is never going to get stuck because it went to sleep just as the other process set the value. Note that this is guaranteed only when the value is set before `process-poke` is called.

Functions that cause specific wait functions to be ready to run (for example `mailbox-send` which causes `mailbox-read` to be ready to run) implicitly pokes a process that waits, so there is no need to use `process-poke` when these functions are used.

## Example

Worker process function:

```
(defun worker-process-function (work-struct)
  (loop (mp:process-wait-local "Waiting for request"
                               'worker-struct-request
                               work-struct)
        (process-request
         (worker-struct-request work-struct)))
        (setf (worker-struct-request work-struct) nil)))
```

Another process distributes requests:

```
(dolist (work-struct *work-structs*)
  (unless (worker-struct-request work-struct)
    (setf (worker-struct-request work-struct) request)
    (mp:process-poke
      (worker-struct-process work-struct)))
  (return work-struct)))
```

This specific example can be implemented a little more simply by `mailbox-read` and `mailbox-send`, but if the wait function needs to check for something else it can be easily added.

## process-private-property *Function*

Summary      Gets or sets the value of a private property of the current process.

Package     `mp`

Signature    `process-private-property indicator &optional default => result`

`(setf process-private-property) value indicator &optional default => result`

Arguments    `indicator`      A Lisp object.

`default`      A Lisp object.

Values       `result`      `value or default`

Description    The function `process-private-property` gets or sets the value that is associated with `indicator` in the private properties of the current process (that is, the result of calling `get-current-process`).

If `indicator` is not associated with a value in the private properties, `process-private-property` returns `default`.

`(setf process-private-property)` overwrites any existing value for `indicator`.

The default value of `default` is `nil`.

Notes        1. Private properties can be read from other processes using `get-process-private-property`, but cannot be set by other processes.

2. Process private property access is faster than than process property access in SMP LispWorks, because the implementation of the latter must deal with parallel setting.

## process-reset

## *Function*

Summary

Resets a process by discarding its current state.

Package

`mp`

Signature

`process-reset process =>`

Arguments

`process` A process.

Values

None.

Description

`process-reset` interrupts the execution of `process` and “throws away” its current state. Upon resuming execution, the process calls its function with its initial argument and priority.

`process-reset` modifies the dynamic execution state of `process`. It performs a non-local exit from the currently run-

ning function, to cause the process's main function to return. `unwind-protect` forms will be run.

`process-reset` does not modify any of the attributes of the process, in particular its priority, items on the plist, or accumulated run-time.

|       |                                                                                                                                                                                                                                                                                                                    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | Since <code>process-reset</code> causes an asynchronous non-local exit, it is possible that it can occur within an <code>unwind-protect</code> cleanup form or before data used by an <code>unwind-protect</code> cleanup form has been initialized. In some cases, not all cleanups within that form will be run. |

| Values                 | <code>process</code> The newly created process.                                                                                                                                                                                                                                                                                                                   |                   |                             |                       |                                                    |                       |                      |                        |                                              |
| Description            | This function creates a new Lisp process with name <code>name</code> . Other properties of <code>process</code> may be specified in keyword/value pairs in <code>keywords</code> :                                                                                                                                                                                |                   |                             |                       |                                                    |                       |                      |                        |                                              |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:priority</code>          | A <code>fixnum</code> representing the priority for the process. If <code>:priority</code> is not supplied, the process priority becomes the value of the variable <code>*default-process-priority*</code> .                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>:mailbox</code>           | A <code>mailbox</code> , a string, <code>t</code> or <code>nil</code> , used to initialize the <code>process-mailbox</code> of <code>process</code> .<br><br>True values specify that <code>process</code> should have a <code>mailbox</code> . A <code>mailbox</code> is used as-is; a string is used as the name of a new mailbox; and <code>t</code> causes it to create a <code>mailbox</code> with the same name as <code>process</code> , that is, <code>name</code> .<br><br>Note that both <code>process-send</code> and <code>process-wait-for-event</code> force the relevant process to have a <code>mailbox</code> . |
| <code>:internal-server</code>   | When true, this indicates that the process is an "internal server", which means that it responds to requests for work from other processes. The main effect of this is that if the only processes that remain are "internal servers", nothing is going to happen, so LispWorks quits. The system marks some of the processes that it creates as "internal server".                                                                                                                                                                                                                                                               |
| <code>:remote-terminator</code> | A function designator for a function of one argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>:local-terminator</code>  | A function designator for a function of no arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>:terminate-by-send</code> | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The new process is preset to apply *function* to *arguments* and runs in parallel, while `process-run-function` returns immediately.

`:remote-terminator`, `:local-terminator` OR `:terminate-by-send` define the Terminate Method of the process, which is what `process-terminate` uses. If more than one of these keyword arguments is supplied, then `:remote-terminator` takes precedence over `:local-terminator` which takes precedence over `:terminate-by-send`.

If `remote-terminator` is supplied, it must be a function of one argument. When `process-terminate` is called, it funcalls `remote-terminator` on the process that `process-terminate` was called on, which normally will be another process. It should then terminate the process somehow. Typically the process itself will be frequently checking some flag which tells it to exit, and the function `remote-terminator` just sets this flag. `remote-terminator` should return non-nil when it is "successful", that is it did something that should cause the process to terminate. `process-terminate` checks the result of the call to `remote-terminator`, and if it is nil it also calls `process-kill` on the process.

If `local-terminator` is supplied, it must be a function of no arguments. When `process-terminate` is called it sends to the process a list with the `local-terminator` as the only element. That relies on the process itself processing what is sent to it and funcalling the function. This is what `general-handle-event` does, which is what system processes tend to use. In particular, all processes that are created by CAPI use it.

If `terminate-by-send` is supplied and non-nil, `process-terminate` sends the process a list containing `current-process-kill` (that is it is the same as `:local-terminator 'current-process-kill`). CAPI processes use this keyword.

**Example**

```
CL-USER 253 > (defvar *stream* *standard-output*)
*STREAM*

CL-USER 254 > (mp:process-run-function
                 "My process"
                 '(:priority 42)
                 #'(lambda (x)
                     (loop for i below x
                           do (and (print i *stream*)
                                    (sleep 1)))
                     finally
                     (print (mp:process-priority
                             mp::*current-process*)
                            *stream*)))
3)
#<MP:PROCESS Name "My process" Priority 850000 State
"Running">

0
1
2
42
CL-USER 255 >
```

| Description | <p>The function <code>process-send</code> queues <i>object</i> in the mailbox of the given process.</p> <p><i>object</i> can any kind of Lisp object, and it is up to the receiving process to interpret it.</p> <p><code>process-send</code> only sends the event: it is the responsibility of the receiving process to actually read the event and then interpret it. Reading is typically done by calling <code>process-wait-for-event</code>. Interpreting the event is up the caller of <code>process-wait-for-event</code>. In the "standard" situation, for</p> |                                                                        |

example in a process started by CAPI, the object will be processed as an event by calling `general-handle-event`.

`process-send` actually uses the `process-mailbox` of *process*, creating a `mailbox` for *process* if it does not already have one. In principle *object* can be read by another process, by calling `mailbox-read` (or `process-wait-for-event`) on the mailbox.

If `change-priority`, which has a default value of `:default`, is non-nil, it controls how the priority of that process is calculated as follows:

- `fixnum` — use the value of `change-priority` as the new priority.
- `t` — set the priority to the interactive priority.
- `:default` — set the priority to the normal running priority.

`error-if-dead-p` defaults to `nil`, which means that if `process-send` is called with a dead process, it just returns false. If `error-if-dead-p` is non-nil, when `process-send` is called on a dead process it signals a continuable error.

`limit` defaults to `nil`. If it is non-nil, it must be a positive integer that specifies the maximum size to which `process-send` may expand the mailbox of the process. When `limit` is non-nil, `process-send` adds the object to the mailbox as if by

```
(mailbox-send-limited mailbox object limit timeout)
```

See `mailbox-send-limited` for details.

`timeout` defaults to `nil` and is used when `limit` is non-nil as described above, otherwise it is ignored.

`process-send` returns true if it put the object in the mailbox of the process and false otherwise. The latter can happen either because the process is dead, or because the process's mailbox is full and reached the size specified by `limit` and `timeout` is non-nil.

| Description                      | <p>This is like <code>process-lock</code>, but <i>sharing-lock</i> must be a "sharing" lock and it will be locked in shared mode. That means that other threads can also lock it in shared mode.</p> <p>Before locking, <code>process-sharing-lock</code> waits for <i>sharing-lock</i> to be free of any exclusive lock, but it does not check for other shared mode use of the same lock.</p> <p>Calls to <code>process-sharing-lock</code> should be matched by calls to <code>process-sharing-unlock</code> with <i>sharing-lock</i>. Normally <code>with-sharing-lock</code> is the best way to achieve this.</p> |                                  |                 |                              |                                                                                           |                             |                                                        |
| Notes                            | <p>It is possible to lock for sharing inside the scope of a sharing lock and inside the scope of an exclusive lock.</p> <p><code>process-sharing-lock</code> is guaranteed to return if it locked <i>sharing-lock</i>, but may throw before locking, as described in</p>                                                                                                                                                                                                                                                                                                                                               |                                  |                 |                              |                                                                                           |                             |                                                        |

## process-sharing-unlock *Function*

|             |                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Removes a sharing lock.                                                                                                                                                                                                                                                                                                                                   |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                                                           |
| Signature   | <code>process-sharing-unlock sharing-lock</code>                                                                                                                                                                                                                                                                                                          |
| Arguments   | <code>sharing-lock</code> A sharing lock.                                                                                                                                                                                                                                                                                                                 |
| Description | <p>The function <code>process-sharing-unlock</code> is the same as <code>process-unlock</code> but for a “sharing” lock.</p> <p>Calls to <code>process-sharing-unlock</code> should be matched by calls to <code>process-sharing-lock</code> with <code>sharing-lock</code>. Normally <code>with-sharing-lock</code> is the best way to achieve this.</p> |
| Notes       | <code>process-sharing-unlock</code> is guaranteed to successfully unlock <code>sharing-lock</code> , but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 278.                                                                                                                                |

| Description         | <p>The function <code>process-stop</code> stops the process <i>process</i>. <i>process</i> must be a full process (that is, not one created by <code>*current-process*</code>).</p> <p><code>process-stop</code> causes <i>process</i> to stop until some other process explicitly wakes it up. If it is called on the current process, the current process stops during the call, and returns from <code>process-stop</code> after the process gets woken up.</p> <p>In SMP LispWorks, if <i>process</i> is not the current process, <code>process-stop</code> returns immediately and the execution of <i>process</i> stops at some point, possibly after <code>process-stop</code> returned. In non-SMP LispWorks if <i>process</i> is not the current process, <i>process</i> stops before <code>process-stop</code> returns.</p> <p>You can wake up a stopped process (that is, make it runnable) by calling <code>process-terminate</code>, <code>process-unstop</code> or <code>process-continue</code>.</p> <p><code>process-interrupt</code> does not wake up a stopped process.</p> <p>There is a discussion of a typical use of <code>process-stop</code> in the section “Stopping and unstopping processes” on page 296.</p> <p><code>process-stop</code> does not return any useful value.</p> |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>process-terminate</code> terminates the process <code>process</code>, which means killing it "nicely". <code>process-terminate</code> invokes the Terminate Method of <code>process</code>, if it has one, otherwise it calls <code>process-kill</code>.</p> <p>The terminate is set either by supplying one of <i>local-terminator</i>, <i>remote-terminator</i> or <i>terminate-by-send</i> in the call to <code>process-run-function</code>, or by a call to <code>current-process-set-terminate-method</code> on the process. See the entry for <code>process-run-function</code> for details.</p> <p>If the process does not have a Terminate Method, <code>process-terminate</code> calls <code>process-kill</code>.</p> <p>If <i>force-timeout</i> is non-nil then <code>process-terminate</code> sets a timer that kills the process after <i>force-timeout</i> seconds.</p> <p>If <i>join-timeout</i> is non-nil then it is the time in seconds to "join" the process, that is waiting for it to die. When <i>join-timeout</i> is non-nil, after invoking the Terminate Method or calling <code>process-kill</code>, <code>process-terminate</code> calls <code>process-join</code> using <i>join-timeout</i> as the timeout, and returns the result.</p> <p><code>process-terminate</code> returns the result of <code>process-join</code> if <i>join-timeout</i> is non-nil, otherwise it returns 0.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. <code>process-terminate</code> is the appropriate way to kill processes, because it gives the process the option to decide when to exit. <code>process-kill</code> kills the process whenever it is not blocking interrupts, which may still be sensitive in some sense.</li> <li>2. When multiprocessing stops (for example when quitting, or saving a session), the system uses first <code>process-terminate</code> and then <code>process-kill</code>, so processes that exit with <code>process-terminate</code> have the chance to clean up as needed.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

3. `process-terminate` is better than `process-kill` only when the process has a Terminate Method. When the process does not have a Terminate Method, `process-terminate` can cause the other to exit in the middle of some sensitive piece of code.

The default is <code>t</code> . |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                  | A boolean.                                                                                                                                                   |
| Description | <p>Attempts to unlock <code>lock</code>. If <code>lock</code> is owned by <code>*current-process*</code>, then <code>process-unlock</code> decrements an internal count. If this count is then zero, <code>lock</code> is unlocked. Note that <code>process-unlock</code> relates only on Lisp processes.</p> <p><code>result</code> is <code>t</code> if the lock was released, and <code>nil</code> otherwise.</p> |                                                                                                                                                              |
| Notes       | <p><code>process-sharing-unlock</code> is guaranteed to successfully unlock <code>lock</code>, but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 278.</p>                                                                                                                                                                                             |                                                                                                                                                              |

## process-unstop *Function*

Summary      Unstops a process.

Package      **mp**

Signature     **process-unstop** *process* => *result*

Arguments    *process*      A **mp:process** object.

Values        *result*      A boolean.

Description    The function **process-unstop** unstops the process *process* if it is stopped.  
  
*process* must be a full process (that is, not one created by **\*current-process\***).  
  
If *process* was stopped (by **process-stop**), it is unstopped and resumes execution.  
  
*result* is **t** if *process* was stopped, and **nil** otherwise.  
  
There is a discussion of a typical use of **process-unstop** in the section “Stopping and unstopping processes” on page 296.

| Description         | <p>The function <code>process-wait</code> suspends the current Lisp process until the predicate <i>wait-function</i> applied to <i>wait-arguments</i> returns true. This is tested periodically by the scheduler, but in situations where you want more control over the timing you should consider using <code>process-wait-local</code> instead of <code>process-wait</code> and then call <code>process-poke</code> in the process that is expected to make the <i>wait-function</i> return true.</p> <p><i>wait-function</i> has several limitations: it must not do a non-local exit, it should not have side effects and (since it is called frequently) it should be efficient.</p> <p>Also, <i>wait-function</i> is called with interrupts blocked. It should therefore not allow interrupts, because this could cause deadlocks.</p> <p><i>wait-reason</i> allows you to find out why a process is waiting via the function <code>process-whostate</code>.</p> |

| Values      | <i>wait-function</i>                                                                                                                                                                                                                                                                                                                                                                          | A function designator. |
| Description | <p>The function <code>process-wait-function</code> returns the function that determines whether the Lisp process waits. The system periodically calls <i>wait-function</i> to decide whether to wake the process up.</p> <p><i>wait-function</i> is applied to <i>wait-arguments</i>, where both <i>wait-function</i> and <i>wait-arguments</i> were passed to <code>process-wait</code>.</p> |                        |
| See also    | <code>process-wait</code>                                                                                                                                                                                                                                                                                                                                                                     |                        |

## process-wait-local Function

|           |                                                                                                 |                               |
|-----------|-------------------------------------------------------------------------------------------------|-------------------------------|
| Summary   | Has the same semantics as <code>process-wait</code> , but does not interact with the scheduler. |                               |
| Package   | <code>mp</code>                                                                                 |                               |

| Description | <p>The function <code>process-wait-local</code> suspends the current Lisp process until the predicate <i>function</i> applied to <i>args</i> returns true.</p> <p><code>process-wait-local</code> has same semantics as <code>process-wait</code>, but is "local", which here means that it does not interact with the scheduler. The scheduler does not call the wait function and hence never wakes the waiting process</p> <p>The wait function <i>function</i> is called only by the calling process, before going to sleep, and whenever it is "poked". A process is typically "poked" by calling <code>process-poke</code>, but all the other process managing functions (<code>process-unstop</code>, <code>process-interrupt</code>, <code>process-terminate</code>) also "poke" the process. Returning from any of the generic Process Waiting functions (see "Generic Process Wait functions" on page 281) or <code>c1:sleep</code> also implicitly pokes the process. A process may be also poked internally.</p> <p>Because the wait function is checked only when the process is poked, it is the responsibility of the application to poke the process when it should check the wait function. This is the disadvantage of <code>process-wait-local</code> and <code>process-wait-local-with-timeout</code>.</p> <p><b>Note:</b> See <code>process-wait-local-with-periodic-checks</code> and <code>process-wait-local-with-timeout-and-periodic-checks</code> for functions that periodically check the wait functions.</p> <p>One advantage of using the "local" waiters is that the wait function is called only by the waiting process. This means that the wait function does not have any of the restrictions that the wait function of <code>process-wait</code> has. In particular:</p> <ol style="list-style-type: none"> <li>1. It does not matter if the wait function is not very fast.<br/>Note however, that it may be called several times, and not always in a predictable way, so it is better not to make it too slow or allocate much. You also cannot rely on any</li> </ol> |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

side effect that is cumulative inside the wait function, except in the call that returns true (because this happens at most once).

2. If there is an unhandled error in the wait function it enters the debugger like normal Lisp code, so it is easier to debug.
3. The wait function is in the dynamic scope of the calling process, and so it sees all the dynamic bindings and can throw to all the catchers. That also means that all the handlers and restarts of the calling process are applicable in the wait function.
4. The wait function can itself call Process Waiting functions or `c1:sleep`, with a small caveat: since these functions may implicitly "poke" the process, if the wait function calls any of them and then returns false, it may be immediately called again (if it returns true then `process-wait-local` itself returns). Normally this is not a problem, because it is still waiting, but it does mean that the wait function is called more times than expected.
5. The wait function, because it can call Process Waiting functions, can use locks without causing errors. Note, however, that if the lock is held, it will cause an internal call to a Process Waiting function, which will "poke" the process and hence cause another call of the wait function (unless it returns true).
6. The wait function is visible in the output of the profiler.

Another advantage of the "local" functions is that they do not interact with the scheduler and so they reduce the overhead of the scheduler.

`process-wait-local` always returns `t`.

| <i>wait-reason</i> | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |           |               |                         |                 |                        |             |                                       |
| <i>period</i>      | A positive real number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                    |           |               |                         |                 |                        |             |                                       |
| <i>function</i>    | A function designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                    |           |               |                         |                 |                        |             |                                       |
| <i>args</i>        | Arguments passed to <i>function</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                    |           |               |                         |                 |                        |             |                                       |
| Description        | <p>The function <code>process-wait-local-with-periodic-checks</code> is like <code>process-wait-local</code>, but also calls the wait function periodically.</p> <p>The <i>period</i> is in seconds.</p> <p>After each call to the function <i>wait-function</i>, the process sleeps at most <i>period</i> seconds, and then checks the wait function. If the process is poked while sleeping, it wakes up, checks the wait function, and then (if the wait function returns <code>nil</code>), sleeps again for at most <i>period</i> seconds.</p> |                    |           |               |                         |                 |                        |             |                                       |
| Notes              | The resolution of the period is dependent on the underlying operating system. Many systems give time-slices of few milliseconds, so the actual period may be out by a few milliseconds. In general, periods of 0.1 seconds or more are reasonably reliable, though not exact. Shorter periods become less and less reliable.                                                                                                                                                                                                                        |                    |           |               |                         |                 |                        |             |                                       |

If the period is short, the wait function is called frequently, and hence there is more overhead for the system. With a reasonable wait function and a period of 0.1 or more, this overhead is probably insignificant. If you use shorter periods, or an expensive wait function, you may want to check what the overhead is. The easiest way to check is to make sure your system is such that the wait function returns `nil`, then run

```
(ignore-errors ; just in case
  (sys:with-other-threads-disabled
    (time (mp:process-wait-local-with-timeout-and-
periodic-checks
      "Timing" 5 period function args))))
```

When this form returns, compare the user and system times (which is what it actually used) to the elapsed time (which should be approximately 5 seconds). That will tell you what fraction of a "CPU" is used by the call. If the user and system time are less than 0.01 seconds, you may want to increase the time to get a more accurate number.

Warning: inside the scope of `with-other-threads-disabled`, the rest of the threads are disabled. So if your wait function ends up waiting for something that has to happen on another thread, your system will be deadlocked.

## **process-wait-local-with-timeout**

## *Function*

#### Summary

Has the same semantics as `process-wait-with-timeout`, but does not interact with the scheduler.

| Description | <p>The function <code>process-wait-local-with-timeout</code> has same semantics as <code>process-wait-with-timeout</code>, but is "local", which here means that it does not interact with the scheduler. The scheduler does not call the wait function and hence never wakes the waiting process.</p> <p>The <i>timeout</i> is in seconds.</p> <p>The circumstances in which the function <i>wait-function</i> is called, and the restrictions on it, are as documented for <code>process-wait-local</code> except that the wait function can additionally be called when it times out.</p> <p><code>process-wait-local-with-timeout</code> returns <code>t</code> if a call to the wait function returns true. It returns <code>nil</code> if it times out.</p> |                                                        |

## `process-wait-local-with-timeout-and-periodic-checks` *Function*

|         |                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------|
| Summary | Like <code>process-wait-local-with-timeout</code> , but also calls the wait function periodically. |
|---------|----------------------------------------------------------------------------------------------------|

|             |                                                                                                                                                                                                                                                                                                                                                                                                |

| Arguments   | <i>wait-reason</i>    | A string describing the reason that the process is waiting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>timeout</i>        | A non-negative <code>real</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | <i>wait-function</i>  | A function to test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <i>wait-arguments</i> | The arguments to apply to <i>wait-function</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <i>bool</i>           | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description |                       | <p>This function uses <code>process-wait</code> to suspend the current Lisp process until the predicate <i>wait-function</i> applied to <i>wait-arguments</i> returns true, or until <i>timeout</i> seconds have passed.</p> <p><i>wait-function</i> is called periodically by the scheduler, but in situations where you want more control over the timing you should consider using <code>process-wait-local</code> instead of <code>process-wait</code> and then call <code>process-poke</code> in the process that is expected to make the <i>wait-function</i> return true.</p> <p><i>wait-function</i> is called with interrupts blocked. It should therefore not allow interrupts, because this could cause deadlocks.</p> <p><i>bool</i> is <code>nil</code> if the timeout occurred before <i>wait-function</i> returned true. <i>bool</i> is true otherwise.</p> |

| Description |                                          | The function <code>processes-count</code> returns the number of Lisp processes that are currently alive.<br><br>The <code>count</code> includes all processes that are alive, that is started executing and did not die. It does not include any thread that was started by foreign code, unless it calls into Lisp, in which case Lisp automatically generates a matching Lisp process which is included in the count.<br><br>In general processes can start and die so the real count may change by the time the function has returned. The only guarantee is that the count was accurate at some point between the time <code>processes-count</code> was called and the time it returns. |

|             | <i>test</i>                                                                                                                                                                                                                                                                                                                                                      | A function designator for a function of two arguments. |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                    | A list.                                                |
| Description | The function <code>pushnew-to-process-property</code> pushes <i>value</i> to the value of the property associated with <i>indicator</i> for the process <i>process</i> . It uses the function <i>test</i> to compare existing property values of <i>process</i> with <i>value</i> and does not push if one matches, in the same way as <code>cl:pushnew</code> . |                                                        |

The default value of *test* is `#'eql`.

If there is a property associated with *indicator*, the value of the property must be a list.

If *process* is not supplied or is `nil`, the current process (that is, the result of calling `get-current-process`) is used.

*result* is the new value of the process property.

The modification is done in a thread-safe way.

|          |                                                                                                                                                                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> . |

|             | <i>process</i> | A process, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>test</i>    | A function designator for a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values      | <i>result</i>  | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description |                | <p>The function <code>remove-from-process-property</code> removes <i>value</i> from the value of the property associated with <i>indicator</i> for the process <i>process</i>. It uses the function <i>test</i> to compare <i>value</i> with existing values, in the same way as <code>cl:remove</code>.</p> <p>The default value of <i>test</i> is <code>#'eql</code>.</p> <p>If there is a property associated with <i>indicator</i>, the value of the property must be a list.</p> <p>If <i>process</i> is not supplied or is <code>nil</code>, the current process (that is, the result of calling <code>get-current-process</code>) is used.</p> <p><i>result</i> is the new value of the process property.</p> <p>The modification is done in a thread-safe way.</p> |
| Notes       |                | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | <p>The function <code>remove-process-property</code> removes the general property associated with <i>indicator</i> from the process <i>process</i>.</p> <p>If <i>process</i> is not supplied or is <code>nil</code>, the current process (that is, the result of calling <code>get-current-process</code>) is used.</p> <p>Note that removing a property is different from setting its value to <code>nil</code>, because when <code>process-property</code> is called with a default for a property that was removed, it returns the default, but for a property that was set to <code>nil</code> it returns <code>nil</code>.</p> <p><i>removedp</i> is true if the property was removed.</p> |
| Notes       | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> .                                                                                                                                                                                                                                                                                                                                                                                                                |

|             | <i>absolute-expiration-time</i> | A non-negative real number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | <i>repeat-time</i>              | A non-negative real number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Values      | <i>timer</i>                    | A timer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description |                                 | <p>The function <code>schedule-timer</code> schedules a timer to expire at a given time after the start of the program. The <i>timer</i> argument is a timer, returned by <code>make-timer</code> or <code>make-named-timer</code>. The <i>absolute-expiration-time</i> argument is a non-negative real number of seconds since the start of the program at which the timer is to expire. If <i>repeat-time</i> is specified, it is a non-negative real number of seconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval.</p> <p>If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the <i>absolute-expiration-time</i> argument. If that argument is <code>nil</code>, the timer is not rescheduled, but the repeat interval is set to the interval specified by the <i>repeat-time</i> argument.</p> <p>The function <code>schedule-timer-relative</code> schedules a timer to expire at a time relative to the call to that function.</p> |
| Example     |                                 | <p>The following example schedules a timer to expire 15 minutes after the start of the program and every 5 minutes thereafter.</p> <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*))  #&lt;Time Event : PRINT&gt;  (mp:schedule-timer timer 900 300)  #&lt;Time Event : PRINT&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Values      | <i>timer</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A timer.                    |
| Description | The function <code>schedule-timer-milliseconds</code> schedules a timer to expire at a given time after the start of the program. The <i>timer</i> argument is a timer returned by <code>make-timer</code> or <code>make-named-timer</code> . The <i>absolute-expiration-time</i> argument is a non-negative real number of milliseconds since the start of the program at which the timer is to expire. If <i>repeat-time</i> is specified, it is a non-negative real number of milliseconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval. |                             |

If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the *absolute-expiration-time* argument. If that argument is `nil`, the timer is not rescheduled, but the repeat interval is set to the interval specified by the *repeat-time* argument.

The function `schedule-timer-relative-milliseconds` schedules a timer to expire at a time relative to the call to that function.

Notes `schedule-timer-milliseconds` has the same precision as `schedule-timer`, but may avoid some allocation when computing the time.

Example The following example schedules a timer to expire 15 minutes after the start of the program and every 5 minutes thereafter.

```
(setq timer
      (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:schedule-timer-milliseconds timer 900000 300000)

#<Time Event : PRINT>
```

| Description | <p>The function <code>schedule-timer-relative</code> schedules a timer to expire at a given time after the call to the function. The <i>timer</i> argument is a timer returned by <code>make-timer</code> or <code>make-named-timer</code>. The <i>relative-expiration-time</i> argument is a non-negative real number of seconds after the call to the function at which the timer is to expire. If <i>repeat-time</i> is specified, it is a non-negative real number of seconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval.</p> <p>If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the <i>relative-expiration-time</i> argument. If that argument is <code>nil</code>, the timer is not rescheduled, but the repeat interval is set to the interval specified by the <i>repeat-time</i> argument.</p> <p>The function <code>schedule-timer</code> schedules a timer to expire at a time relative to the start of the program.</p> |                                                                                                                                           |

**Example** The following example schedules a timer to expire 5 seconds after the call to `schedule-timer-relative` and every 5 seconds thereafter.

```
(setq timer
      (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:schedule-timer-relative timer 5 5)

#<Time Event : PRINT>
```

## **schedule-timer-relative-milliseconds**

*Function*

**Summary** Schedules a timer to expire at a given time after this function is called.

**Package** `mp`

**Signature** `schedule-timer-relative-milliseconds timer relative-expiration-time &optional repeat-time => timer`

**Arguments** `timer` A timer.

`relative-expiration-time` A non-negative real.

`repeat-time` A non-negative real.

**Values** `timer` A timer.

Each time the timer expires, it is rescheduled to expire after this repeat interval.</p> <p>If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the <code>relative-expiration-time</code> argument. If that argument is <code>nil</code>, the timer is not rescheduled, but the repeat interval is set to the interval specified by the <code>repeat-time</code> argument.</p> <p>The function <code>schedule-timer-milliseconds</code> schedules a timer to expire at a time relative to the start of the program.</p> |
| Notes       | <code>schedule-timer-relative-milliseconds</code> has the same precision as <code>schedule-timer-relative</code> , but may avoid some allocation when computing the time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Example     | <p>The following example schedules a timer to expire 5 seconds after the call to <code>schedule-timer-relative-milliseconds</code> and every 5 seconds thereafter.</p> <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*))  #&lt;Time Event : PRINT&gt;  (mp:schedule-timer-relative-milliseconds timer 5000   5000)  #&lt;Time Event : PRINT&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|              |                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | A class of objects for synchronizing access to a shared resource that contains some number of available units.                                                                                                                                                                          |
| Package      | <code>mp</code>                                                                                                                                                                                                                                                                         |
| Superclasses | <code>t</code>                                                                                                                                                                                                                                                                          |
| Description  | Instances of the system class <code>semaphore</code> are used for synchronizing access to a shared resource that contains some number of available units. They are made by <code>make-semaphore</code> and are used <code>semaphore-acquire</code> and <code>semaphore-release</code> . |

| Description | <p>The function <code>semaphore-acquire</code> acquires <i>count</i> units from the <code>semaphore</code> <i>sem</i>.</p> <p>It attempts to atomically decrement the semaphore's unit count by <i>count</i>. If this gives a non negative result, then it changes the semaphore's unit count accordingly and returns true. The default value of <i>count</i> is 1.</p> <p>However, if decrementing the semaphore's unit count would result in a negative number then <code>semaphore-acquire</code> waits until the semaphore's unit count is larger than <i>count</i> and tries again. If <i>wait-reason</i> is true, then it is used as the thread's <i>wait-reason</i> when waiting for the semaphore.</p> <p>If <i>timeout</i> is <code>nil</code>, <code>semaphore-acquire</code> can wait forever. Otherwise, if the semaphore count cannot be decremented within <i>timeout</i> seconds, then <code>semaphore-acquire</code> returns false and the semaphore is unaffected. Pass <i>timeout</i> 0 if you do not want to wait at all.</p> |                                                        |
| Notes       | <p>You can get the current unit count of a semaphore by calling <code>semaphore-count</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                        |

| Arguments   | <i>new-limit</i> | An integer in the exclusive range (0,1000000) or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values      | <i>result</i>    | An integer in the exclusive range (0,1000000).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                  | The function <code>set-funcall-async-limit</code> limits the number of asynchronous calls (by <code>funcall-async</code> or <code>funcall-async-list</code> ) which can run in parallel. Further asynchronous calls are queued, and when a running call finishes another call starts.<br><br>When <i>new-limit</i> is an integer the limit is set to <i>new-limit</i> , and <i>result</i> is the previous limit.<br><br>When <i>new-limit</i> is <code>nil</code> , the limit is not changed and <i>result</i> is the current limit.<br><br>The default limit is 5, which is adequate if <code>funcall-async</code> and/or <code>funcall-async-list</code> are only used occasionally. If you use them often, you may want to increase this limit to between 10 and 30. A larger limit probably does not make sense. |

|             | <i>condvar</i>         | A condition-variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>condvar-timeout</i> | A non-negative <code>real</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <i>predicate</i>       | A function designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <i>args</i>            | Arguments to <i>predicate</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Values      | <i>result</i>          | See below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description |                        | The function <code>simple-lock-and-condition-variable-wait</code> is a variant of <code>lock-and-condition-variable-wait</code> that does not take keyword arguments. Also it takes the arguments of the <i>predicate</i> as <code>&amp;rest</code> . It interprets and acts on the arguments just like <code>lock-and-condition-variable-wait</code> .<br><br><code>simple-lock-and-condition-variable-wait</code> returns the result of calling <i>predicate</i> or the wait, like <code>lock-and-condition-variable-wait</code> when <i>return-function</i> is not supplied. |
| Notes       |                        | <code>simple-lock-and-condition-variable-wait</code> does not take wait reason arguments, so you should give names to the <code>lock</code> <i>lock</i> and the <code>condition-variable</code> <i>condvar</i> for debugging (by passing <i>name</i> in <code>make-lock</code> and <code>make-condition-variable</code> ).                                                                                                                                                                                                                                                      |

| Description | <p>The function <code>symeval-in-process</code> reads the value of the symbol <i>symbol</i> in the process <i>process</i> if it is bound dynamically. The global value of <i>symbol</i> is never returned.</p> <p>If <i>symbol</i> is not bound in <i>process</i>, then <i>value</i> and <i>flag</i> are both <code>nil</code>. If <i>symbol</i> is bound in <i>process</i> but <code>makunbound</code> has been called within the dynamic scope of the binding, <i>value</i> is <code>nil</code> and <i>flag</i> is <code>:unbound</code>. Otherwise, <i>value</i> is the value of <i>symbol</i> and <i>flag</i> is <code>t</code>.</p> <p>In addition, the form</p> <pre>(setf (symeval-in-process symbol process) value)</pre> <p>sets the value of <i>symbol</i> to <i>value</i> in <i>process</i>. It is an error if <i>process</i> has no binding for <i>symbol</i>. This <code>setf</code> form returns <i>value</i> as specified by Common Lisp.</p> |
| Notes       | <code>symeval-in-process</code> is mostly intended for debugging. It is OK to call it on a thread known to be idle, or in <code>process-wait</code> or <code>process-stop</code> , but it should not be called while the thread is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <i>Function</i> |         |              |                     |  |

|                   |                 |
|-------------------|-----------------|
| <b>timer-name</b> | <i>Function</i> |
|-------------------|-----------------|

Summary      Returns the name of a specified timer.

Package      `mp`

Signature     `timer-name timer => name`

Signature     `(setf timer-name) name timer => name`

Arguments    `timer`      A timer

Values       `name`      A string

Description     The function `timer-name` returns the name of the specified `timer`. The `timer` argument is a timer returned by `make-timer` or `make-named-timer`. If the timer has no name, `timer-name` returns `nil`.

The name of a timer created by either `make-timer` or `make-named-timer` can be set by means of the following syntax:

```
(setf (mp:timer-name timer) name)
```

Example      

```
(setq timer
      (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:timer-name timer)

NIL

(setf (mp:timer-name timer) 'timer-1)

TIMER-1
```

```
(mp:timer-name timer)
  TIMER-1

| Arguments   | <code>timer</code> A timer                                                                                                                                                                                                                                                                                                           |
| Values      | <code>result</code> A timer or <code>nil</code>                                                                                                                                                                                                                                                                                      |
| Description | If the specified timer has been scheduled to expire at a time after the call to <code>unschedule-timer</code> , this function unschedules the timer and returns the timer. Otherwise, the function returns <code>nil</code> .<br><br>The argument is a timer, returned by <code>make-timer</code> or <code>make-named-timer</code> . |
| Example     | <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*))  #&lt;Time Event : PRINT&gt;  (mp:schedule-timer-relative timer 60)  #&lt;Time Event : PRINT&gt;  (mp:unschedule-timer timer)  #&lt;Time Event : PRINT&gt;  (mp:timer-expired-p timer)  T</pre>                                                                  |

|             | <i>wait-function</i>          | A function designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>wait-args</i>              | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      | <i>result</i>                 | <code>t</code> or <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description |                               | <p>The function <code>wait-processing-events</code> does not return until one of two conditions is met:</p> <ul style="list-style-type: none"> <li>• <i>timeout</i> is non-nil and <i>timeout</i> seconds have passed.<br/>In this case, <i>result</i> is <code>nil</code>.</li> <li>• <i>wait-function</i> returns a true value.<br/>In this case, <i>result</i> is <code>t</code>.</li> </ul> <p><i>wait-reason</i> provides the value returned by <code>process-whos-state</code> when called on the current process.</p> <p><i>wait-function</i> is called periodically with arguments <i>wait-args</i>. <i>wait-function</i> may be called many times and in several places. Therefore <i>wait-function</i> should be fast and make no assumptions about its dynamic context.</p> <p><code>wait-processing-events</code> processes all events sent to the current process, including system events such as window messages on Microsoft Windows, and objects sent by other processes via <code>process-send</code>. In the latter case, the objects must be lists of the form <code>(function . arguments)</code>, which cause <i>function</i> to be applied to <i>arguments</i> (the values are discarded).</p> |

`wait-processing-events` is a useful alternative to `sleep` in a situation where you want to process events to see window updates and so on.

## with-exclusive-lock *Macro*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Holds a sharing <code>lock</code> in exclusive mode while evaluating its body, and then unlocks the lock.                                                                                                                                                                                                                                                                                                                                                                                                            |  |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Signature   | <code>with-exclusive-lock (sharing-lock &amp;optional whostate timeout) &amp;body body =&gt; results</code>                                                                                                                                                                                                                                                                                                                                                                                                          |  |
| Arguments   | <p><i>sharing-lock</i>      A sharing <code>lock</code>.<br/><i>whostate</i>      The status of the process while <i>sharing-lock</i> is locked, as seen in the Process Browser.<br/><i>timeout</i>      A non-negative <code>real</code> or <code>nil</code>.<br/><i>body</i>      The forms to execute</p>                                                                                                                                                                                                         |  |
| Values      | <i>results</i> The values returned from evaluating <code>body</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| Description | The macro <code>with-exclusive-lock</code> is the same as <code>with-lock</code> , except that <i>sharing-lock</i> must be a "sharing" <code>lock</code> , that is, created with the argument <i>sharing</i> true in <code>make-lock</code> . It waits until <i>sharing-lock</i> is completely free, that is, not locked in a sharing mode and is not locked in exclusive mode by another thread. It then locks <i>sharing-lock</i> in exclusive mode, evaluates <code>body</code> and unlocks <i>sharing-lock</i> . |  |
| Notes       | It is not possible to hold an exclusive lock in the scope of a <i>sharing-lock</i> on the same <code>lock</code> , and trying to do it will cause                                                                                                                                                                                                                                                                                                                                                                    |  |

the process to hang. Whether it is possible to hold an exclusive lock inside an exclusive-lock of the same `lock` is determined by the `recursivelp` argument in `make-lock`.

**with-interrupts-blocked***Macro*

Summary      Evaluates code with interrupts blocked.

Package      `mp`

Signature      `with-interrupts-blocked &body body => results`

Arguments      `body`                  Code

Values      `results`                  Values returned by evaluating `body`.

Description      Evaluates `body` with interrupts blocked. This actually expands to

`(mp:allowing-block-interrupts t ,@body)`

which means it also allows you to change the blocking of interrupts.

See the entry for `allowing-block-interrupts` for full details.

See also      `allowing-block-interrupts`

**with-lock***Macro*

Summary      Executes a body of code while holding a lock.

| Values      | <code>result</code>   | The result of executing <code>body</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description |                       | <code>with-lock</code> executes <code>body</code> while holding <code>lock</code> , and unlocks <code>lock</code> when <code>body</code> exits. This is the recommended way of using a <code>lock</code> . The value of <code>body</code> is returned normally. <code>body</code> is not executed if <code>lock</code> could not be locked, in which case, <code>with-lock</code> returns <code>nil</code> . The <code>timeout</code> and <code>whostate</code> are used as specified by <code>process-lock</code> . |

| Description | <p>The macro <code>with-sharing-lock</code> is like <code>with-lock</code>, but <i>sharing-lock</i> must be a "sharing" lock and will be locked in shared mode. That means that other threads can also lock it in shared mode.</p> <p>Before locking, <code>with-sharing-lock</code> waits for <i>sharing-lock</i> to be free of any exclusive lock, but it does not check for other shared mode use of the same lock.</p> |                                                                                                |
| Notes       | <p>It is possible to lock for sharing inside the scope of sharing lock and inside the scope of an exclusive lock.</p>                                                                                                                                                                                                                                                                                                      |                                                                                                |

| <b>without-interrupts</b> |                                                                                                                         | <i>Macro</i>                                      |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Summary                   | <p>Causes any interrupts that occur during the execution of a body of code to be queued, in non-SMP LispWorks only.</p> |                                                   |
| Package                   | <code>mp</code>                                                                                                         |                                                   |
| Signature                 | <code>without-interrupts &amp;rest <i>body</i> =&gt; <i>result</i></code>                                               |                                                   |
| Arguments                 | <i>body</i>                                                                                                             | The forms to execute while interrupts are queued. |

|             |               |                                                                                                                                                                                                                                                                                                       |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>result</i> | The result of executing <i>body</i> .                                                                                                                                                                                                                                                                 |
| Description |               | While <i>body</i> is executing, all interrupts (for example, preemption, keyboard break etc.) are queued. They are executed when <i>body</i> exits.                                                                                                                                                   |
| Notes       |               | <code>without-interrupts</code> is not supported in SMP LispWorks, that is on Microsoft Windows, Mac OS X, Linux, FreeBSD, AIX and x86/x64 Solaris platforms.                                                                                                                                         |
| Example     |               | To ensure that the seconds and milliseconds slots are always consistent in non-SMP LispWorks, you can use <code>without-interrupts</code> within the function which sets them.                                                                                                                        |
|             |               | <pre>(defstruct elapsed-time   seconds   milliseconds)  (defun update-elapsed-time-atomically   (elapsed-time seconds milliseconds)   (mp:without-interrupts     (setf (elapsed-time-seconds elapsed-time) seconds           (elapsed-time-milliseconds elapsed-time)           milliseconds)))</pre> |

|           |               | <i>Macro</i>                                                                               |
|-----------|---------------|--------------------------------------------------------------------------------------------|
| Summary   |               | Identifies forms which should not be preempted during execution, in non-SMP LispWorks only |
| Package   |               | <code>mp</code>                                                                            |
| Signature |               | <code>without-preemption &amp;rest body =&gt; result</code>                                |
| Arguments | <i>body</i>   | The forms to be evaluated atomically.                                                      |
| Values    | <i>result</i> | The result of executing <i>body</i> .                                                      |

|             |                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Identifies forms which should not be preempted during execution.                                                                                              |
| Notes       | <code>without-preemption</code> is not supported in SMP LispWorks, that is on Microsoft Windows, Mac OS X, Linux, FreeBSD, AIX and x86/x64 Solaris platforms. |

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Allows preemption to happen in low safety code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Signature   | <code>yield</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description | Normally code compiled at safety 0 cannot be preempted because the necessary checks are omitted. This can be overcome by calling <code>yield</code> at regular intervals. Usually there is no need to call this if you use functions from the <code>common-lisp</code> package because these are not compiled at safety 0, but for example if you find that preemption is not working in a loop with no function calls, <code>yield</code> can be useful. Note that <code>process-allow-scheduling</code> also allows preemption, but also checks the wait functions of other processes. |
| See also    | <code>process-allow-scheduling</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## The PARSERGEN Package

This chapter describes symbols available in the **PARSERGEN** package, the Lisp-Works parser generator.

This functionality is discussed in detail in Chapter 21, “The Parser Generator”.

| defparser | <i>Macro</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Creates a parsing function of the given name for the grammar defined.                                                                                                                                                                                                                                                                                                                                                                                                     |

| Arguments   | <p><b>name</b>                    The name of the parser.</p> <p><b>accept-without-eoi-p</b><br/>A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | <p>The rules define the productions of the grammar and the associated forms define the semantic actions for the rules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | <p><b>parsing-function</b> The symbol name of the parsing function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description | <p><b>defparser</b> creates a parsing function of the given name for the grammar defined. The parsing function is defined as if by:</p> <pre>(defun &lt;name&gt; (lexer &amp;optional (symbol-to-string #'<b>identify</b>))</pre> <p>The <i>lexer</i> parameter is a function of no arguments that returns two values: the next grammar token on the input and the associated semantic value.</p> <p>The optional <i>symbol-to-string</i> function can be used to define a printed representation of the grammar tokens. The function should take a grammar symbol as its single argument and returns an object to be used as a print representation for the grammar token.</p> <p>When <i>accept-without-eoi-p</i> is true, the parser accepts the input as soon as the top level rule matches completely rather than waiting for end of input (eoi). The default value of <i>accept-without-eoi-p</i> is false.</p> <p>For a full description and examples, see Chapter 21, “The Parser Generator”.</p> |

## The SERIAL-PORT Package

This chapter describes the symbols available in the **SERIAL-PORT** package.

The Serial Port functionality is loaded into LispWorks by evaluating

```
(require "serial-port")
```

See **open-serial-port** for platform-specific details.

|           | <i>Function</i>                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Attempts to open the named serial port and return a <b>serial-port</b> object.                                                                                                                                                                                                     |

| Description | <p>The function <b>open-serial-port</b> attempts to open the serial port <i>name</i> and return a <b>serial-port</b> object.</p> <p>On Windows, <i>name</i> is passed directly to <b>CreateFile()</b>. For ports COM<i>n</i> where <i>n</i> &gt; 9, you must take care to pass the real port name expected by Windows. At the time of writing this issue is documented at <a href="http://support.microsoft.com/kb/115831">http://support.microsoft.com/kb/115831</a>.</p> <p>On non-Windows platforms, <i>name</i> should be the device file name (for example <code>"/dev/cu.usbmodem14111"</code>).</p> <p>If any of <i>baud-rate</i>, <i>data-bits</i>, <i>stop-bits</i> and <i>parity</i> are supplied then the corresponding serial port settings are changed. The values of <i>baud-rate</i> and <i>data-bits</i> should each be an appropriate integer. The value of <i>stop-bits</i> should be 1, 1.5 (Windows only) or 2. The value of <i>parity</i> should be one of the keywords <b>:even</b>, <b>:none</b> or <b>:odd</b>, or on Windows, <b>:mark</b> or <b>:space</b>.</p> <p>The arguments <i>cts-flow-p</i> and <i>dsr-flow-p</i> control whether write operations respond to CTS and DSR flow control. A non-nil value means that the corresponding flow control is used. Note that <i>dsr-flow-p</i> is only supported on Windows.</p> <p>The arguments <i>dtr</i> and <i>rts</i> control whether read operations generate DTR or RTS flow control. If the value is <b>:handshake</b> then the corresponding flow control signal is generated automatically. If the value is <b>nil</b> or <b>t</b> then the initial state of the flow control signal is set and automatic flow control is not used. See <b>set-serial-port-state</b> for manual flow control. Note: the value <b>:handshake</b> for <i>dtr</i> is only supported on Windows.</p> <p>The argument <i>read-interval-timeout</i> can be used to control the maximum time to wait between each input character. The</p> |                                                                      |

`value :none` means that reading will not wait for characters at all, only returning whatever is already in the input buffer

The arguments `read-total-base-timeout` and `read-total-byte-timeout` can be used to control the maximum time to wait for a sequence of characters. The arguments `write-total-base-timeout` and `write-total-byte-timeout` can be used to control the maximum time to wait when transmitting a sequence of characters. For both reading and writing the timeout is given by the expression:

```
base_timeout + nchars * byte_timeout
```

The default value of each of `read-total-base-timeout`, `read-total-byte-timeout`, `write-total-base-timeout` and `write-total-byte-timeout` is `nil` and this means that the corresponding parameter in the OS is left unchanged and there is zero timeout. Otherwise the value should be a non-negative real number specifying a timeout in seconds.

## get-serial-port-state Function

Summary Queries various aspects of the state of a serial port.

Package [serial-port](#)

Signature `get-serial-port-state serial-port keys => state`

Arguments `serial-port` A `serial-port` object.

`keys` A list of keywords.

Values `state` A list.

Description The function `get-serial-port-state` queries various aspects of the state of the serial port associated with `serial-port`.

The argument `keys` should be a list of one or more of the keywords `:dsr` and `:cts`. These cause `get-serial-port-state` to check the DSR and CTS lines respectively.

The result `state` is a list giving the state of each line in the same order as they appear in the argument `keys`.

## serial-port Class

Summary The class of objects representing serial ports.

Package [serial-port](#)

Description The class `serial-port` is the class of objects representing serial ports. These are constructed by `open-serial-port` - do not create them directly.

See also      **open-serial-port**

**read-serial-port-char**                          *Function*

Summary      Reads a character from a serial port.

Package      **serial-port**

Signature      **read-serial-port-char** *serial-port* &optional *timeout-error-p*  
*timeout-char* => *char*

Arguments      *serial-port*      A **serial-port** object.

*timeout-error-p*    A boolean.

*timeout-char*     A character.

Values      *char*      A character.

Description      The function **read-serial-port-char** reads and returns a character from the serial port associated with *serial-port*.

A timeout will occur if the character is not available before the read timeout (as specified by values given when the serial port was opened by **open-serial-port**).

When a timeout occurs, if *timeout-error-p* is non-nil, then an error of type **serial-port-timeout** is signaled, otherwise *timeout-char* is returned. The default value of *timeout-error-p* is t.

| Description | <p>The function <code>read-serial-port-string</code> reads characters from the serial port associated with <code>serial-port</code> and places them in <code>string</code>, bounded by <code>start</code> and <code>end</code>.</p> <p>The default values of <code>start</code> and <code>end</code> are 0 and <code>nil</code> (interpreted as the length of <code>string</code>) respectively. The number of characters requested is the difference between <code>end</code> and <code>start</code>.</p> <p>If the number of characters actually read, <code>nread</code>, is less than the number requested, then if <code>timeout-error-p</code> is non-nil an error of type <code>serial-port-timeout</code> is signaled.</p> <p>If <code>nread</code> is the number of characters requested, or if <code>timeout-error-p</code> is <code>nil</code>, <code>nread</code> is returned.</p> <p>The default value of <code>timeout-error-p</code> is <code>t</code>.</p> |                                                      |

|-------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     |                        | Writes a string to a serial port.                                                                                                                                                                         |
| Package     |                        | <code>serial-port</code>                                                                                                                                                                                  |
| Signature   |                        | <code>write-serial-port-string string serial-port &amp;optional<br/>timeout-error-p &amp;key start end -&gt; nwritten</code>                                                                              |
| Arguments   | <i>string</i>          | A string.                                                                                                                                                                                                 |
|             | <i>serial-port</i>     | A <code>serial-port</code> object.                                                                                                                                                                        |
|             | <i>timeout-error-p</i> | A boolean.                                                                                                                                                                                                |
|             | <i>start, end</i>      | Bounding index designators for <i>string</i> .                                                                                                                                                            |
| Values      | <i>result</i>          | The string <i>string</i> or <code>nil</code> .                                                                                                                                                            |
| Description |                        | The function <code>write-serial-port-string</code> writes characters from the subsequence of <i>string</i> bounded by <i>start</i> and <i>end</i> to the serial port associated with <i>serial-port</i> . |

The default values of *start* and *end* are 0 and `nil` (interpreted as the length of *string*) respectively.

If the characters are successfully written then *string* is returned.

A timeout will occur if the characters cannot be written before the write timeout (as specified by values given when the serial port was opened by `open-serial-port`).

When a timeout occurs, if *timeout-error-p* is non-nil, then an error of type `serial-port-timeout` is signaled, otherwise `nil` is returned. The default value of *timeout-error-p* is `t`.

## The SQL Package

This chapter describes the symbols available in the `sql` package which implements Common SQL. You should use this chapter in conjunction with Chapter 23, “Common SQL”. In particular that chapter contains more information about the Oracle LOB interface (that is, those functions with names beginning `sql:ora-lob-`).

On Microsoft Windows, Linux, x86/x64 Solaris, FreeBSD, AIX and Mac OS X, Common SQL is included only in LispWorks Enterprise Edition.

| accepts-n-syntax | <i>Function</i>                                                                              |
|------------------|----------------------------------------------------------------------------------------------|
| Summary          | Return whether a database connection accepts or requires the N syntax for non-ASCII strings. |
| Package          | <code>sql</code>                                                                             |

| Values      | <code>nil-t-required</code> <code>t</code> , <code>nil</code> or <code>:required</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description | The function <code>accepts-n-syntax</code> returns <code>nil-t-required</code> to indicate the behavior of the N syntax for string literals in the database specified by <i>database</i> . (The N syntax prefixes a string literal by the character N.)<br><br><code>nil-t-required</code> can be one of:<br><br><code>nil</code> the database will give an error.<br><code>T</code> the database accepts it but does not require it.<br><code>:required</code> the database requires it (at least in some cases).<br><br>Currently, Microsoft SQL Server (which can be used via ODBC) is the only supported database that requires the N syntax for non-ASCII strings. SQLite and Microsoft Access (via ODBC) give errors. The other supported databases accept the syntax but do not need it.<br><br>If you use the “Symbolic SQL syntax” on page 358, then you can use the <code>string</code> pseudo-operator, which is described in “SQL string literals” on page 366 to obtain the correct syntax. |

|             | <i>attribute</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | An attribute from <i>table</i> .                   |
|             | <i>database</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A database.                                        |
|             | <i>owner</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <i>nil</i> , <i>:all</i> or a string.              |
| Values      | <i>datatype</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A keyword or list denoting a vendor-specific type. |
| Description | <p>The function <b>attribute-type</b> returns the type of the attribute specified by <i>attribute</i> in the table given by <i>table</i>. The database, in which <i>table</i> is found, has a default value of <b>*default-database*</b>.</p> <p>If <i>owner</i> is <i>nil</i>, only user-owned attributes are considered. This is the default.</p> <p>If <i>owner</i> is <i>:all</i>, all attributes are considered.</p> <p>If <i>owner</i> is a string, this denotes a username and only attributes owned by <i>owner</i> are considered.</p> <p><i>datatype</i> demotes a vendor-specific type. Examples in a MS Access database are <b>:integer</b>, <b>:longchar</b> and <b>:datetime</b>. When <i>datatype</i> is a list, the second element is the length of the type, for example <b>(:varchar 255)</b>.</p> |                                                    |
| Example     | <p>To print the type of every attribute in the database, do</p> <pre>(loop for tab in       (sql:list-tables)       do         (loop for att in               (sql:list-attributes tab)               do                 (format t "&amp;Table ~S Attribute ~S Type ~S"                         tab att                         (sql:attribute-type att tab))))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                    |

| Summary             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Controls the caching of attribute type information.                |
| Package             | sql                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                    |
| Signature           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <code>cache-table-queries table &amp;key database action</code>    |
| Arguments           | <i>table</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A string naming a table, <code>:default</code> or <code>t</code> . |
|                     | <i>database</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A database.                                                        |
|                     | <i>action</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <code>t</code> , <code>nil</code> or <code>:flush</code> .         |
| Description         | <p>The function <code>cache-table-queries</code> provides per-table control on the caching in a particular database connection of attribute type information using during update operations.</p> <p>If <i>table</i> is a string, it is the name of the table for which caching is to be altered. If <i>table</i> is <code>t</code>, then the <i>action</i> applies to all tables. If <i>table</i> is <code>:default</code>, then the default caching action is set for those tables which do not have an explicit setting.</p> <p><i>database</i> specifies the database connection, its default value is the value of <code>*default-database*</code>.</p> <p><i>action</i> specifies the caching action. The value <code>t</code> means cache the attribute type information. The value <code>nil</code> means do not cache the attribute type information. If <i>table</i> is <code>:default</code>, the setting applies to all tables which do not have an explicit setup.</p> <p>The value <code>:flush</code> means remove any existing cache for <i>table</i> in <i>database</i>, but continue to cache.</p> |                                                                    |

`cache-table-queries` should be called with `action :flush` when the attribute specifications in `table` have changed.

### **\*cache-table-queries-default\***                                                                  *Variable*

Package      `sql`

Initial value      `nil`

Description      The variable **\*cache-table-queries-default\*** provides the default attribute type caching behavior.  
It allowed values are as described for the `action` argument of `cache-table-queries`.

See also      `cache-table-queries`

### **commit**                                                                  *Function*

Summary      Commits changes made to a database.

Package      `sql`

Signature      `commit &key database => nil`

Arguments      `database`      A database.

Values      `nil`

Description      The function `commit` commits changes made to the database specified by `database`, which is **\*default-database\*** by default.

*This chapter applies to the Enterprise Edition only*

Example      This example changes records in a database, and uses `commit` to make those changes permanent.

```
(insert-records :into [emp]
                    :attributes '(x y z)
                    :values '(a b c))
(update-records [emp]
                :attributes [dept]
                :values 50
                :where [= [dept] 40])
(delete-records :from [emp]
                :where [> [salary] 300000])
(commit)
```

| Signature      | <code>connect connection-spec &amp;key if-exists database-type interface name encoding signal-rollback-errors default-table-type default-table-extra-options date-string-format sql-mode prefetch-rows-number prefetch-memory sqlite-keywords =&gt; database</code>                                                                                         |
| Arguments      | <code>connection-spec</code> The connection specifications.<br><code>if-exists</code> A keyword.<br><code>database-type</code> A database type.<br><code>interface</code> A displayed CAPI element, or <code>nil</code> .<br><code>name</code> A Lisp object.<br><code>encoding</code> A keyword naming an encoding.<br><code>signal-rollback-errors</code> |

`nil`, the keyword `:default`, or a function designator.

`default-table-type` A string, the keyword  
`:support-transactions`, or `nil`.

`default-table-extra-options`

A string or `nil`.

`date-string-format` A string, or the keyword `:standard`, or `nil`.

`sql-mode` A string or `nil`.

`prefetch-rows-number`

An integer or the keyword `:default`.

`prefetch-memory` An integer or the keyword `:default`.

`sqlite-keywords` A property list of keywords and values specific to SQLite.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |

| Values      | <code>database</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A database. |
| Description | <p>The function <code>connect</code> opens a connection to a database of type <code>database-type</code>.<br/> The allowed values for <code>database-type</code> are <code>:odbc</code>, <code>:odbc-driver</code>, <code>:mysql</code>, <code>:postgresql</code>, <code>:oracle8</code> and <code>:oracle</code>, though not all of these are supported on some platforms. See “Supported databases” on page 333 for details of per-platform database support.</p> <p>The default for <code>database-type</code> is the value of <code>*default-database-type*</code>.</p> <p><code>connect</code> sets the variable <code>*default-database*</code> to an instance of the database opened, and returns that instance.</p> <p>If <code>connection-spec</code> is a list it is interpreted as a plist of keywords and values. Some of the keywords are <code>database-type</code> specific: see “Connecting to Oracle”, “Connecting to ODBC”, “Connecting to MySQL” or “Connecting to PostgreSQL” as appropriate.</p> |             |

General *connection-spec* keywords are:

- |                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:username</b>   | User name                                                                                                                                                                                                                    |
| <b>:password</b>   | Password                                                                                                                                                                                                                     |
| <b>:connection</b> | A specification of the connection. In general, this is supposed to be sufficient information (other than the username and password) to open a connection. The precise meaning varies according to the <i>database-type</i> . |

If *connection-spec* is a string, it is interpreted canonically as:

*username/password@connection*

where *connection* can be omitted along with the '@' in cases when there is a default connection, *password* can be omitted along with the preceding '/', and *username* can be omitted if there is a default user. For example, if you have an Oracle user matching the current Unix username and that does not need a password to connect, you can call

```
(connect "/")
```

Specific *database-types* may allow more elaborate syntax, but conforming to the pattern above. See the section “Initialization” on page 334 for details.

Additionally for *database-types* :**odbc** and :**odbc-driver**, if *connection-spec* does not include the '@' character then the string is interpreted in a special way, for backward compatibility with LispWorks 4.4 and earlier versions. See the section “Connecting to ODBC” on page 339 for details.

*name* can be passed to explicitly specify the name of the connection. If *name* is supplied then it is used as-is for the connection name. Therefore it can be found by another call to **connect** and calls to **find-database**. Connection names are compared with **equalp**. If *name* is not supplied, then a unique database name is constructed from *connection-spec* and a counter.

If *name* is supplied then existing connections are found by comparing their name with *name* and then *if-exists* modifies the behavior of `connect` as follows:

|                        |                                                                                        |
|------------------------|----------------------------------------------------------------------------------------|
| <code>:new</code>      | Makes a new connection even if connections to the same database already exist.         |
| <code>:warn-new</code> | Makes a new connection but warns about existing connections.                           |
| <code>:error</code>    | Makes a new connection but signals an error for existing connections.                  |
| <code>:warn-old</code> | Selects an existing connection if there is one (and warns), or makes a new connection. |
| <code>:old</code>      | Selects an existing connection if there is one, or makes a new one.                    |

The default value of *if-exists* is the value of `*connect-if-exists*`.

*interface* is used if `connect` needs to display a dialog to ask the user for username and password. If *interface* is a CAPI element, this is used. If *interface* is any other value (the default value is `nil`), and `connect` is called in a process which is associated with a CAPI interface, then this CAPI interface is used. *interface* has been added because dialogs asking for passwords can fail otherwise. This depends on the driver that the datasource uses: the problem has only been observed using MS SQL on Microsoft Windows.

*encoding* specifies the encoding to use in the connection. The value should be a keyword naming an acceptable encoding, or `nil` (the default). The value `:unicode` is accepted for all *database-types*, and this will try to make a connection that can support sending and retrieving double-byte string values. Other values are *database-type* specific:

|                     |                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:mysql</code> | If <i>encoding</i> is <code>nil</code> or <code>:default</code> then the encoding is chosen according to the default character set of the connection (if available) |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

and if that fails the encoding `:utf-8` is used. The other recognized values of *encoding* are `:unicode`, `:utf-8`, `:ascii`, `:latin-1`, `:euc` and `:sjis`.

`:unicode` uses `:utf-8` internally.

- `:postgresql` If *encoding* is `nil` or `:default` LispWorks does not set anything in the connection. If the connection character set is SQL\_ASCII, LispWorks uses `:latin-1` to convert to and from Lisp strings, otherwise it uses `:utf-8`. If *encoding* is one of the keywords listed below, LispWorks uses it as the external format for converting to and from Lisp strings, and LispWorks also sets the connection character set to the corresponding string:

| Keyword               | character-set | alias                   |
|-----------------------|---------------|-------------------------|
| <code>:utf-8</code>   | UTF-8         | <code>:unicode</code>   |
| <code>:latin-1</code> | SQL_ASCII     |                         |
| <code>:ascii</code>   | SQL_ASCII     |                         |
| <code>:gbk</code>     | GBK           |                         |
| <code>:euc-jp</code>  | EUC_JP        | <code>:euc</code>       |
| <code>:sjis</code>    | SJIS          | <code>:shift-jis</code> |

An alias maps to the corresponding keyword.

In addition, *encoding* can be a string or a cons of a keyword and a string. If it is a string LispWorks uses `:utf-8` as the external format, and sets the connection character set to the string. If it is a cons, the keyword (the car) is used as the external format, and the string (cdr) is used to set the character set.

See "character set support" in the PostgreSQL manual for known character sets.

- `:oracle` The only recognized values of *encoding* are `nil` and `:unicode`.

**:oracle8**      *encoding* is ignored.

**:odbc OR :odbc-driver**

The valid values of *encoding* are **:unicode** or **:nil**. When *encoding* is **:nil** it uses the default multibyte encoding.

**:sqlite**      If *encoding* is **:default**, **:unicode** or **:utf-8** then UTF-8 is used (by calling the C function `sqlite3_open_v2`). If *encoding* is **:utf-16** or **:utf-16-native**, then UTF-16 in the native byte order is used (by calling the C function `sqlite3_open16`). It is not obvious in what circumstances UTF-16 is better and it is made available only because the underlying library supports it.

*signal-rollback-errors* controls what happens when an attempted **rollback** causes an error, for databases that do not support rollback properly (for example MySQL with the default settings). For *database-types* other than **:mysql signal-rollback-errors** is ignored and such an error is always signaled. For *database-type* **:mysql signal-rollback-errors** is interpreted as follows:

**:nil**      Ignore the error.

**:default**      If *default-table-type* is **:support-transactions**, "innodb" or "bdb", then rollback errors are signaled. Otherwise rollback errors are not signaled.

#### Function designator

The function *signal-rollback-errors* should take two arguments: the database object and a string (for an error message). The function is called when a rollback signaled an error.

The default value of *signal-rollback-errors* is **:default**.

*default-table-type* specifies the default value of the `:type` argument to `create-table`. See `create-table` for details. The default value of *default-table-type* is `nil`.

*default-table-extra-options* specifies the default value of the `:extra-options` argument to `create-table`. See `create-table` for details. The default value of *default-table-extra-options* is `nil`.

*date-string-format* specifies which format to use to represent dates. If the value is a string, it should be appropriate for the *database-type*. The value `:standard` means that the standard SQL date format is used. If the value is `nil` (the default), then the date format is not changed. Currently only *database-type :oracle* uses the value of *date-string-format*, and in this case it must be a valid date format string for Oracle.

*sql-mode* specifies the mode of the SQL connection for *database-type :mysql*. By default (that is, when *sql-mode* is not supplied) `connect` sets the mode of the connection to ANSI, by executing this statement:

```
"set sql_mode='ansi'"
```

*sql-mode* can be supplied as `nil`, in which case no statement is executed. Otherwise it should be a string which is a valid setting for `sql_mode`, and then `connect` executes the statement:

```
set sql_mode='sql-mode'
```

When *database-type* is not `:mysql`, *sql-mode* is ignored.

*prefetch-rows-number* and *prefetch-memory* are used when *database-type* is `:oracle`, and specify the amount of data to prefetch when performing queries. *prefetch-rows-number* is the number of rows to prefetch, with default value 100. *prefetch-memory* is the maximum number of bytes to prefetch, with default value `#x100000`. *prefetch-rows-number* and *prefetch-memory* can both also have the value `:default`, which allows the database to choose the amount to prefetch.

`sqlite-keywords` is used only when connecting to SQLite (`database-type` is `:sqlite`) and is ignored otherwise. See “SQLite connection keywords” on page 344 for more details.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes               | All the Common SQL functions that accept the keyword argument <code>:database</code> use <code>find-database</code> to find the database if the given value is not a database. Therefore these functions can now find only databases that were opened with an explicit <i>name</i> :                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                     | <pre>(connect ... :name name ...)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Compatibility notes | <p>LispWorks 4.4 (and previous versions) use <i>connection-spec</i> passed to <code>connect</code> as the database name. <code>connect</code> checks whether a connection with this name already exists (according to the value of <code>if-exists</code>). <code>find-database</code> can be used to find a database using this name.</p> <p>LispWorks 5.0 (and later versions) does not use <i>connection-spec</i> as the name. Instead, by default it generates a name from the <i>connection-spec</i>. The name is intended to be unique (by including a counter). Thus normally <code>connect</code> will not find an existing connection even if it is called again with identical value of <i>connection-spec</i>.</p> |

Example The following example connects LispWorks to the `info` database.

```
(connect "info")
```

The next example connects to the ODBC database `personnel` using the username "admin" and the password "secret".

```
(connect "personnel/admin/secret" :database-type :odbc)
```

The next example opens a connection to MySQL which treats quotes as in ANSI but does not set other ANSI features:

```
(sql:connect "me/mypassword/mydb"
             :sql-mode "ANSI_QUOTES")
```

## **\*connect-if-exists\***

*Variable*

|                  |                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary          | The default value for the <i>if-exists</i> keyword of the <b>connect</b> function.                                                                              |
| Package          | <b>sql</b>                                                                                                                                                      |
| Initial value    | <b>:error</b>                                                                                                                                                   |
| Description      | The variable <b>*connect-if-exists*</b> is the default value for the <i>if-exists</i> keyword of the <b>connect</b> function. It can take the following values: |
| <b>:new</b>      | Instructs <b>connect</b> to make a new connection even if connections to the same database already exist.                                                       |
| <b>:warn-new</b> | Instructs <b>connect</b> to make a new connection but warn about existing connections.                                                                          |
| <b>:error</b>    | Instructs <b>connect</b> to make a new connection but signal an error for existing connections.                                                                 |
| <b>:warn-old</b> | Instructs <b>connect</b> to select an old connection if one exists (and warns) or make a new one.                                                               |
| <b>:old</b>      | Instructs <b>connect</b> to select an old connection if one exists or make a new one.                                                                           |

## **connected-databases** *Function*

Summary      Returns a list of connected databases.

Package      **sql**

Signature      **connected-databases => database-list**

Arguments      None.

Values      **database-list**      A list of connected databases.

Description      The function **connected-databases** returns a list of the databases LispWorks is connected to.

See also      **connect**  
**disconnect**  
**status**  
**find-database**  
**database-name**

## **create-index** *Function*

Summary      Creates an index for a table.

Package      **sql**

Signature      **create-index name &key on unique attributes database =>**

Arguments      **name**      The name of the index.

**on**      The name of a table.

**unique**      A boolean.

*This chapter applies to the Enterprise Edition only*

|-------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>attributes</i> | A list of attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>database</i>   | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values      |                   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description |                   | The function <code>create-index</code> creates an index called <i>name</i> on the table specified by <i>on</i> . The attributes of the table to index are given by <i>attributes</i> . Setting <i>unique</i> to <code>t</code> includes <code>UNIQUE</code> in the SQL index command, specifying that the columns indexed must contain unique values.<br><br>The default value of <i>unique</i> is <code>nil</code> . The default value of <i>database</i> is <code>*default-database*</code> . |
| Example     |                   | <pre>(create-index [manager]   :on [emp] :unique t :attributes '([ename] [sal]))</pre>                                                                                                                                                                                                                                                                                                                                                                                                          |
| See also    |                   | <code>*default-database*</code><br><code>drop-index</code><br><code>create-table</code>                                                                                                                                                                                                                                                                                                                                                                                                         |

|           |                      | <i>Function</i>                                                                       |
|-----------|----------------------|---------------------------------------------------------------------------------------|
|           | <b>create-table</b>  |                                                                                       |
| Summary   |                      | Creates a table.                                                                      |
| Package   |                      | <code>sql</code>                                                                      |

| Description | <p>The function <code>create-table</code> creates a table called <i>name</i> and defines its columns and other properties with <i>description</i>. The argument <i>description</i> is a list containing lists of attribute-name and type information pairs.</p> <p>The default value of <i>database</i> is <code>*default-database*</code>.</p> <p><i>type</i> and <i>extra-options</i> are treated in a <i>database-type</i> specific way. Currently only <i>database-type</i> <code>:mysql</code> uses these options, as follows.</p> <p>If <i>type</i> is not supplied, it defaults to the value (if any) of <i>default-table-type</i> that was supplied to <code>connect</code>. If <i>extra-options</i> is not supplied, it defaults to the value (if any) of <i>default-table-extra-options</i> that was supplied to <code>connect</code>.</p> <p><i>type</i>, if non-nil, is used as argument to TYPE in the SQL statement:</p> <pre>create table MyTable (<i>column-specs</i>) TYPE = <i>type</i></pre> <p>except that if <i>type</i> is <code>:support-transactions</code> then <code>create-table</code> will attempt to make tables that support transactions, by using the type <code>innodb</code>.</p> <p><i>extra-options</i> (if non-nil) is appended in the end of this SQL statement.</p> <p>When <i>database-type</i> is not <code>:mysql</code>, <i>type</i> and <i>extra-options</i> are ignored.</p> |
| Example     | <p>The following code:</p> <pre>(create-table [manager]   '(([id] (char 10) not-null)     ([salary] (number 8 2))))</pre> <p>is equivalent to the following SQL:</p> <pre>CREATE TABLE MANAGER   (ID CHAR(10) NOT NULL, SALARY NUMBER(8,2))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## **create-view**

*Function*

Summary      Creates a view using a specified query.

Package      `sql`

Signature      `create-view name &key as column-list with-check-option database =>`

Arguments      `name`      The view to be created.

`as`      A SQL query statement.

`column-list`      A list.

`with-check-option`

                A boolean.

`database`      A database.

Values      None.

Description      The function `create-view` creates a view called `name` using the `as` query and the optional `column-list` and `with-check-option`. The `column-list` argument is a list of columns to add to the view. The `with-check-option` adds `WITH CHECK OPTION` to the resulting SQL.

The default value of `with-check-option` is `nil`. The default value of `database` is `*default-database*`.

Example      This example creates the view `manager` with the records in the employee table whose department is 50.

```
(create-view [manager] :as [select [*]
                           :from [emp]
                           :where [= [dept] 50]])
```

## create-view-from-class *Function*

Summary      Creates a view in a database based on a class that defines the view.

Package      **sql**

Signature     **create-view-from-class** *class* &**key** *database* =>

Arguments     *class*                A class.  
                 *database*            A database.

Values        None.

Description    The function **create-view-from-class** creates a view in *database* based on *class* which defines the view. The argument *database* has a default value of **\*default-database\***.

| Description | The functions <code>decode-db-standard-date</code> and <code>decode-db-standard-timestamp</code> take a Lisp universal time and convert it to a SQL DATE or TIMESTAMP respectively. |                                                                                                                                                                                                                                                                                                                             |
|             |                                                                                                                                                                                     | The format of the date is YYYY-MM-DD.                                                                                                                                                                                                                                                                                       |
|             |                                                                                                                                                                                     | The format of the timestamp is YYYY-MM-DD HH:MM:SS.                                                                                                                                                                                                                                                                         |
|             |                                                                                                                                                                                     | <code>stream</code> is interpreted as in <code>cl:format</code> . If <code>stream</code> is <code>nil</code> then the string representing the DATE or TIMESTAMP is returned, otherwise the string is written to the stream and <code>nil</code> is returned. The default value of <code>stream</code> is <code>nil</code> . |
|             |                                                                                                                                                                                     | When <code>quoted</code> is true, the date or timestamp is quoted (by single quote). This is useful when these functions are used while building a SQL command string, and the result should be interpreted as a string. The default value of <code>quoted</code> is <code>nil</code> .                                     |

## \*default-database\*

*Variable*

|               |                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The default database in database operations.                                                                                                       |
| Package       | <code>sql</code>                                                                                                                                   |
| Initial value | <code>nil</code>                                                                                                                                   |
| Description   | The variable <code>*default-database*</code> is set by <code>connect</code> and specifies the default database to be used for database operations. |

See also      **connect**

**\*default-database-type\***                          *Variable*

Summary      Specifies the default type of database.

Package      **sql**

Initial value      **nil**

Description      The variable **\*default-database-type\*** specifies the default type of database. You can set this or it is initialized by the **initialize-database-type** function.

LispWorks supports the values shown in “Supported databases” on page 333.

See also      **initialize-database-type**

**\*default-update-objects-max-len\***                          *Variable*

Summary      The default maximum number of objects supplying data for a query when updating remote joins.

Package      **sql**

Initial value      **nil**

Description      The variable **\*default-update-objects-max-len\*** provides the default value of the *max-len* argument in the function **update-objects-joins**.

See also      **update-objects-joins**

In addition the slot option <code>:type</code> is treated specially for View Classes.</p> <p><code>:db-kind</code> may be one of <code>:base</code>, <code>:key</code>, <code>:join</code>, or <code>:virtual</code>. The default is <code>:base</code>. Each value is described below:</p> <table><tr><td><code>:base</code></td><td>This indicates that this slot corresponds to an ordinary attribute of the database view. You can name the database attribute by using the keyword <code>:column</code>. By default, the database attribute is named by the slot.</td></tr><tr><td><code>:key</code></td><td>This indicates that this slot corresponds to part of the unique key for this view. A <code>:key</code> slot is also a <code>:base</code> slot. All View Classes must have <code>:key</code> fields that uniquely distinguish the instances, to maintain object identity.</td></tr></table> | <code>:base</code> | This indicates that this slot corresponds to an ordinary attribute of the database view. You can name the database attribute by using the keyword <code>:column</code> . By default, the database attribute is named by the slot. | <code>:key</code>         | This indicates that this slot corresponds to part of the unique key for this view. A <code>:key</code> slot is also a <code>:base</code> slot. All View Classes must have <code>:key</code> fields that uniquely distinguish the instances, to maintain object identity. |                    |                                        |                            |                                     |
| <code>:base</code>         | This indicates that this slot corresponds to an ordinary attribute of the database view. You can name the database attribute by using the keyword <code>:column</code> . By default, the database attribute is named by the slot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                                                                          |                    |                                        |                            |                                     |
| <code>:key</code>          | This indicates that this slot corresponds to part of the unique key for this view. A <code>:key</code> slot is also a <code>:base</code> slot. All View Classes must have <code>:key</code> fields that uniquely distinguish the instances, to maintain object identity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                                                                   |                           |                                                                                                                                                                                                                                                                          |                    |                                        |                            |                                     |

To specify a key which spans multiple slots, each of the slots should have `:db-kind :key`. The underlying requirement is that tuples of the form (key1 ... keyN) are unique. The `:db-kind :key` slots do not need to be keys in the table.

**`:join`** This indicates that this slot corresponds to a join. A slot of this type will contain View Class objects.

**`:virtual`** This indicates that this slot is an ordinary CLOS slot not associated with a database column.

A join is defined by the slot option `:db-info`, which takes a list. Items in the list may be:

**`:join-class class-name`**

This is the class to join on.

**`:home-key slot-name`**

This is the slot of the defining class to be a subject for the join. The argument *slot-name* may be an element or a list of elements, where elements can be symbols, `nil`, strings, integers or floats.

**`:foreign-key slot-name`**

This is the name of the slot of the `:join-class` to be a subject for the join. The *slot-name* may be an element or a list of elements, where elements can be symbols, `nil`, strings, integers or floats.

*This chapter applies to the Enterprise Edition only*

**:target-slot** *target-slot*

This is the name of a **:join** slot in **:join-class**. This is optional and is only specified if you want the defining slot to contain instances of this target slot as opposed to those of **:join-class**. The actual behavior depends on the value of *set*. An example of its usage is when the **:join-class** is an intermediate class and you are really only interested in it as a route to the **:target-slot**.

**:retrieval** *retrieval-time*

*retrieval-time* can be **:deferred**, which defers filling this slot from the database until the slot itself is accessed. This is the default value.

*retrieval-time* can alternatively be **:immediate** which generates the join SQL for this slot whenever a query is generated on the class. In other words, this is an intermediate class only, which is present for the purpose of joining two entities of other classes together. When *retrieval-time* is **:immediate**, then *set* is **nil**.

**:set** *set*

When *set* is **t** and *target-slot* is defined, the slot will contain a list of pairs (*target-value join-instance*) where *target-value* is the value of the target slot and *join-instance* is the corresponding instance of the join class.

When *set* is **t** and *target-slot* is undefined, the slot will contain a list of instances of the join class.

When *set* is `nil` the slot will contain a single instance.

The default value of *set* is `t`.

The syntax for `:home-key` and `:foreign-key` means that an object from a join class will only be included in the join slot if the values from *home-key* are `equal` to the values in *foreign-key*, in order. These values are calculated as follows: if the element in the list is a symbol it is taken to be a slot name and the value of the slot is used, otherwise the element is taken to be the value. See the second example below.

The `:type` slot option is treated specially for View Classes. There is a need for stringent type-checking in View Classes because of the translation into database data, and therefore `:type` is mandatory for slots with `:db-kind :base` or `:key`. Some methods are provided for type checking and type conversion. For example, a `:type` specifier of `(string 10)` in SQL terms means allow a character type value with length of less than or equal to 10. The following Lisp types are accepted for *type*, and correspond to the SQL type shown:

|                                 |            |
|---------------------------------|------------|
| <code>(string n)</code>         | CHAR(n)    |
| <code>integer</code>            | INTEGER    |
| <code>(integer n)</code>        | INTEGER(n) |
| <code>float</code>              | FLOAT      |
| <code>(float n)</code>          | FLOAT(n)   |
| <code>sql:universal-time</code> | TIMESTAMP  |

Class Options    `def-view-class` recognizes the following class options in addition to the standard class options defined for `defclass`:

- `(:base-table table-name)`

The slots of the class *name* will be read from the table *table-name*. If you do not specify the `:base-table` option, then *table-name* defaults to the name of the class.

**Description** The macro `def-view-class` creates a class called *name* which maps onto a database view. Such a class is called a View Class.

The macro `def-view-class` extends the syntax of `defclass` to allow special *base slots* to be mapped onto the attributes of database views (presently single tables). When a `select` query that names a View Class is submitted, then the corresponding database view is queried, and the slots in the resulting View Class instances are filled with attribute values from the database.

If *superclasses* is `nil` then `standard-db-object` automatically becomes the superclass of the newly-defined View Class. If *superclasses* is `nil`, it must include `standard-db-object`.

**Examples** The following example shows a class corresponding to the traditional *employees* table, with the employee's department given by a join with the *departments* table.

```
(def-view-class employee (standard-db-object)
  ((employee-number :db-kind :key
                    :column empno
                    :type integer)
   (employee-name :db-kind :base
                  :column ename
                  :type (string 20)
                  :accessor employee-name)
   (employee-department :db-kind :base
                         :column deptno
                         :type integer
                         :accessor employee-department)
   (employee-job :db-kind :base
                 :column job
                 :type (string 9))
   (employee-manager :db-kind :base
                      :column mgr
                      :type integer)
   (employee-location :db-kind :join
                       :db-info (:join-class department
   :retrieval :deferred
   :set nil
   :home-key
   employee-department
   :foreign-key
   department-number
   :target-slot
   department-loc)
                       :accessor employee-location)
   (:base-table emp))
```

The following example illustrates how elements or lists of elements can follow `:home-key` and `:foreign-key` in the `:db-info` slot option.

```
(def-view-class flex-schema ()
  ((name       :type (string 8) :db-kind :key)
   (description :type (string 256)))
  (classes :db-kind :join
            :db-info (:home-key name
                                :foreign-key schema-name
                                :join-class flex-class
                                :retrieval :deferred)))
  (:base-table flex_schema))
```

*This chapter applies to the Enterprise Edition only*

```
(def-view-class flex-class ()
  ((schema-name :type (string 8) :db-kind :key
     :column schema_name)
   (name       :type (string 32) :db-kind :key)
   (base-name  :type (string 64) :column base_name)
   (super-classes :db-kind :join
     :db-info (:home-key
               (schema-name name)
               :foreign-key
               (schema-name class-name)
               :join-class
               flex-superclass
               :retrieval :deferred))
   (schema :db-kind :join
     :db-info (:home-key schema-name
                           :foreign-key name
                           :join-class flex-schema
                           :set nil))
   (properties :db-kind :join
     :db-info (:home-key (schema-name name ""))
               :foreign-key
               (schema-name class-name slot-name)
               :join-class flex-property
               :retrieval :deferred)))
  (:base-table flex_class))

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>delete-instance-records <i>instance</i> =&gt;</code>                                                                                                                                                                                       |
| Arguments   | <code><i>instance</i></code> An instance of a View Class.                                                                                                                                                                                        |
| Values      | None.                                                                                                                                                                                                                                            |
| Description | The function <code>delete-instance-records</code> deletes the records represented by <i>instance</i> from the database associated with it. If <i>instance</i> has no associated database, <code>delete-instance-records</code> signals an error. |

## destroy-prepared-statement *Function*

Summary      Destroys a **prepared-statement** and frees its resources.

Package      **sql**

Signature      **destroy-prepared-statement** *prepared-statement* => **nil**

Arguments      *prepared-statement*

                  A **prepared-statement**.

Description      The function **destroy-prepared-statement** destroys the **prepared-statement** *prepared-statement* and frees its resources. It should be called before closing the database associated with *prepared-statement*. A destroyed **prepared-statement** can be reused by calling **set-prepared-statement-variables** with a new database.

**destroy-prepared-statement** always returns **nil**.

## disable-sql-reader-syntax *Function*

Summary      Turns off square bracket syntax.

Package      **sql**

Signature      **disable-sql-reader-syntax** =>

Arguments      None.

|             |                                                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | None.                                                                                                                                                                                                                |
| Description | The function <code>disable-sql-reader-syntax</code> turns off square bracket syntax and sets state so that <code>restore-sql-reader-syntax-state</code> will make the syntax disabled if it is consequently enabled. |
| See also    | <code>enable-sql-reader-syntax</code><br><code>locally-disable-sql-reader-syntax</code><br><code>locally-enable-sql-reader-syntax</code><br><code>restore-sql-reader-syntax-state</code>                             |

## disconnect *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Summary     | Closes a connection to a database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |

| Values      | <code>success</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A boolean.  |
| Description | <p>The function <code>disconnect</code> closes a connection to a database specified by <code>database</code>. If successful, <code>success</code> is <code>t</code> and if only one other connection exists, <code>*default-database*</code> is reset.</p> <p>The default value for <code>database</code> is <code>*default-database*</code>. If <code>database</code> is a database object, then it is used directly. Otherwise, the list of connected databases is searched to find one with <code>database</code> as its connection specifications (see <code>connect</code>). If no such database is found, then if <code>error</code> and <code>database</code> are both non-nil an error is signaled, otherwise <code>disconnect</code> returns <code>nil</code>.</p> |             |

*This chapter applies to the Enterprise Edition only*

Example      `(disconnect :database "test")`

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Summary     | Repeatedly binds a set of variables to the results of a query, and executes a body of code using the bound variables.                                                                                                                                                                                                 |       |
| Package     | sql                                                                                                                                                                                                                                                                                                                   |       |
| Signature   | <pre>do-query ((&amp;rest args) query &amp;key database not-inside-transaction get-all) &amp;body body =&gt;</pre>                                                                                                                                                                                                    |       |
| Arguments   | <p><i>args</i> A set of variables.</p> <p><i>query</i> A database query or a <code>prepared-statement</code> containing a query.</p> <p><i>database</i> A database.</p> <p><i>not-inside-transaction</i> A generalized boolean.</p> <p><i>get-all</i> A generalized boolean.</p> <p><i>body</i> A Lisp code body.</p> |       |
| Values      | None.                                                                                                                                                                                                                                                                                                                 |       |
| Description | The macro <code>do-query</code> repeatedly executes <i>body</i> within a binding of <i>args</i> on the attributes of each record resulting from <i>query</i> . <code>do-query</code> returns no values.                                                                                                               |       |

The default value of *database* is **\*default-database\***.

*not-inside-transaction* and *get-all* may be useful when fetching many records through a connection with *database-type* **:mysql**. Both of these arguments have default value **nil**. See the section “Special considerations for iteration functions and macros” on page 375 for details.

|         |                                                                                                                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | The following code repeatedly binds the result of selecting an entry in <code>ename</code> from the table <code>emp</code> to the variable <code>name</code> , and then prints <code>name</code> using the Lisp function <code>print</code> . |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
(do-query ((name) [select [ename] :from [emp]])
          (print name))
```

## drop-index *Function*

|         |                                   |
|---------|-----------------------------------|
| Summary | Deletes an index from a database. |
|---------|-----------------------------------|

|         |                  |
|---------|------------------|
| Package | <code>sql</code> |
|---------|------------------|

|           |                                                       |
|-----------|-------------------------------------------------------|
| Signature | <code>drop-index index &amp;key database =&gt;</code> |
|-----------|-------------------------------------------------------|

|           |                                                                   |
|-----------|-------------------------------------------------------------------|
| Arguments | <i>index</i> The name of an index.<br><i>database</i> A database. |
|-----------|-------------------------------------------------------------------|

|        |       |
|--------|-------|
| Values | None. |
|--------|-------|

|             |                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>drop-index</code> deletes <i>index</i> from <i>database</i> .<br>The default value of <i>database</i> is <b>*default-database*</b> . |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>drop-view</code> deletes <i>view</i> from <i>database</i> .<br>The default value of <i>database</i> is <code>*default-database*</code> .  |
| Notes       | <code>DROP VIEW</code> is not implemented in MS Access SQL, so <code>drop-view</code> does not work with that database. Use <code>drop-table</code> instead. |
| See also    | <code>create-view</code><br><code>*default-database*</code><br><code>drop-index</code><br><code>drop-table</code>                                            |

|                       | <b>Function</b>                                                                                                                                                                                                                       |                    |          |                       |             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----------|-----------------------|-------------|
| Summary               | Deletes a view from a database based on a class defining the view.                                                                                                                                                                    |                    |          |                       |             |

| <code>database</code> | A database.                                                                                                                                                                                                                           |                    |          |                       |             |
| Values                | None.                                                                                                                                                                                                                                 |                    |          |                       |             |
| Description           | The function <code>drop-view-from-class</code> deletes a view or base table from <i>database</i> based on <i>class</i> which defines that view. The argument <i>database</i> has a default value of <code>*default-database*</code> . |                    |          |                       |             |
| See also              | <code>create-view-from-class</code><br><code>*default-database*</code><br><code>drop-view</code>                                                                                                                                      |                    |          |                       |             |

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>execute-command</code> executes the SQL command specified by <code>sql-exp</code> for the database specified by <code>database</code> , which has a default value of <code>*default-database*</code> . The argument <code>sql-exp</code> may be any SQL statement other than a query.<br><br>To run a stored procedure, pass an appropriate string. The call to the procedure needs to be wrapped in a PL/SQL <code>BEGIN END</code> pair, for example: |

|             | <code>count</code>                                                                                                                                                                                                                                                                                                                                                                                                  | An integer.                                |
| Description | <p>The function <code>find-database</code>, given a string <code>database</code>, searches amongst the connected databases for one matching the name <code>database</code>.</p> <p>If there is exactly one such database, it is returned and the second return value <code>count</code> is 1. If more than one databases match and <code>errorp</code> is <code>nil</code>, then the most recently connected of</p> |                                            |

the matching databases is returned and *count* is the number of matches. If no matching database is found and *errorp* is *nil*, then *nil* is returned. If none, or more than one, matching databases are found and *errorp* is true, then an error is signaled.

If the argument *database* is a database, it is simply returned.

## **initialize-database-type** *Function*

Summary      Initializes a database type.

Package      `sql`

Signature      `initialize-database-type &key database-type => type`

Arguments      *database-type*      A database type.

Values      *type*      A database type.

Description      The function `initialize-database-type` initializes a database type by loading code and appropriate database libraries according to the value of *database-type*. If `*default-database-type*` is not initialized, this function initializes it. It adds *database-type* to the list of initialized types. The initialized database type is returned.

Example      The following example shows how to use `initialize-database-type` to initialize the `:odbc` database type.

```
(require "odbc")
(in-package sql)
(setf *default-database-type* :odbc)
(initialize-database-type)
(print *initialized-database-types*)
```

The ODBC database type is now initialized, and connections can be made to ODBC databases.

## \*initialized-database-types\*

*Variable*

Summary A list of initialized database types.

Package `sql`

Initial value `nil`

Description The variable `*initialized-database-types*` contains a list of database types that have been initialized by calls to `initialize-database-type`.

See also `initialize-database-type`

## insert-records

*Function*

Summary Inserts a set of values into a table.

Package `sql`

Signature `insert-records &key into attributes values av-pairs query database`

Arguments `into` A database table.

*This chapter applies to the Enterprise Edition only*

|             | <i>database</i>   | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      |                   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description |                   | <p>The function <code>insert-records</code> inserts records into the table <i>into</i>.</p> <p>The records created contain <i>values</i> for <i>attributes</i> (or <i>av-pairs</i>). The argument <i>values</i> is a list of values. If <i>attributes</i> is supplied then <i>values</i> must be a corresponding list of values for each of the listed attribute names.</p> <p>If <i>av-pairs</i> is non-nil, then both <i>attributes</i> and <i>values</i> must be <code>nil</code>.</p> <p>If <i>query</i> is non-nil, then neither <i>values</i> nor <i>av-pairs</i> should be. <i>query</i> should be a query expression, and the attribute names in it must also exist in the table <i>into</i>.</p> <p>The default value of <i>database</i> is <code>*default-database*</code>.</p> |
| Example     |                   | <p>In the first example, the Lisp expression</p> <pre>(insert-records :into [person]   :values '("abc" "Joe" "Bloggs" 10000 3000 nil             "plumber"))</pre> <p>is equivalent to the following SQL:</p> <pre>INSERT INTO PERSON   VALUES ('abc','Joe',          'Bloggs',10000,3000,NULL,'plumber')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

In the second example, the LispWorks expression

```
(insert-records :into [person]
  :attributes '(person_id income surname occupation)
  :values '("aaa" 10 "jim" "plumb"))
```

is equivalent to the following SQL:

```
INSERT INTO PERSON
  (PERSON_ID, INCOME, SURNAME, OCCUPATION)
  VALUES ('aaa', 10, 'jim', 'plumb')
```

The following example demonstrates how to use `:av-pairs`.

```
(insert-records :into [person] :av-pairs
  '((person_id "bbb") (surname "Jones")))
```

| Values      | None.                                                                                                                                                                                                                                                                                                                                                                     |                              |
| Description | <p>The function <code>instance-refreshed</code> is called inside <code>select</code> when its <code>refresh</code> argument is true and the instance <code>instance</code> has just been updated.</p> <p>The supplied method on <code>standard-db-object</code> does nothing. If your application needs to take action when a View Class instance has been updated by</p> |                              |

```
(select ... :refresh t)
```

then add an `instance-refresh` method specializing on your subclass of `standard-db-object`.

| Arguments   | <i>table</i>    | A table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>database</i> | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <i>owner</i>    | <code>nil</code> , <code>:all</code> or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values      | <i>result</i>   | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description |                 | <p>The function <code>list-attribute-types</code> returns type information for the attributes in the table given by <i>table</i>. <i>database</i> has a default value of <code>*default-database*</code>.</p> <p>If <i>owner</i> is <code>nil</code>, only user-owned attributes are considered. This is the default.</p> <p>If <i>owner</i> is <code>:all</code>, all attributes are considered.</p> <p>If <i>owner</i> is a string, this denotes a username and only attributes owned by <i>owner</i> are considered.</p> <p><i>result</i> is a list in which each element is a list (<i>attribute datatype precision scale nullable</i>). <i>attribute</i> is a string denoting the attribute name. <i>datatype</i> is the vendor-specific type as described in <code>attribute-type</code>. <i>nullable</i> is 1 if the attribute accepts the value NULL, and 0 otherwise.</p> |
| Notes       |                 | When using ODBC to connect to Access database, the <i>nullable</i> value is not reliable, at least on version 7.1. There seems to be                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

a bug in the driver. Using ODBC with other DBMS works as documented.

**Example** To print the type of every attribute in the database, do

```
(loop for tab in
      (sql:list-tables)
      do
        (loop for type-info in
              (sql:list-attribute-types tab)
              do
                (format t "~&Table ~S Attribute ~S Type ~S"
                        tab
                        (first type-info)
                        (second type-info))))
```

## list-attributes *Function*

**Summary** Returns a list of attributes from a table in a database.

**Package** **sql**

**Signature** **list-attributes** *table* &**key** *database owner* => *result*

**Arguments** *table* A table in the database.

*database* A database.

*owner* *nil*, **:all** or a string.

**Values** *result* A list of attributes.

**Description** The function **list-attributes** returns a list of attributes from *table* in *database*, which has a default value of **\*default-database\***.

*This chapter applies to the Enterprise Edition only*

If *owner* is `nil`, only user-owned attributes are considered.  
This is the default.

If *owner* is `:all`, all attributes are considered.

If *owner* is a string, this denotes a username and only  
attributes owned by *owner* are considered.

## **list-classes** *Function*

Summary      Returns a list of View Classes connected to a given database.

Package      `sql`

Signature      `list-classes &key database root-class test => result-list`

Arguments      `database`      A database.

`root-class`      A class.

`test`      A test function.

Values      `result-list`      A list of class objects.

Description      The function `list-classes` collects all the classes below  
`root-class` (which defaults to `standard-db-object`) that are  
connected to the given database specified by `database`, and  
which satisfy the `test` function. The default for the `test` argu-  
ment is `c1:identity`.

By default, `list-classes` returns a list of all the classes con-  
nected to the default database, `*default-database*`.

| Accessors   | <code>lob-stream-lob-locator</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description | <p>The class <code>lob-stream</code> implements LOB streams in the Oracle LOB interface.</p> <p>A <code>lob-stream</code> for input can be returned from <code>select</code> or <code>query</code> by specifying <code>:input-stream</code> as the type to return for the LOB column.</p> <p>A <code>lob-stream</code> for output can be returned from <code>select</code> or <code>query</code> by specifying <code>:output-stream</code> as the type to return for the LOB column.</p> <p>A <code>lob-stream</code> can be attached to an existing LOB locator by creating the stream explicitly.</p> <p><i>direction</i> specifies whether the stream is for input or output. The default value of <i>direction</i> is <code>:input</code>.</p> <p>By default, if the stream is closed the LOB locator is freed, unless <code>free-lab-locator-on-close</code> is passed as <code>nil</code>. The default value of <code>free-lab-locator-on-close</code> is <code>t</code>.</p> |
| Example     | <p>This creates an input stream connected to the LOB locator <i>lob-locator</i>:</p> <pre>(make-instance 'lob-stream :lob-locator <i>lob-locator</i>)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|             |                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | None.                                                                                                                                                                                                                                   |
| Values      | None.                                                                                                                                                                                                                                   |
| Description | The function <code>locally-disable-sql-reader-syntax</code> turns off square bracket syntax and does not change syntax state. This ensures that <code>restore-sql-reader-syntax-state</code> restores the current enable/disable state. |
| Example     | The intended use of <code>locally-disable-sql-reader-syntax</code> is in a file:                                                                                                                                                        |
|             | <pre>#.(locally-disable-sql-reader-syntax) &lt;Lisp code not using [...] syntax&gt; #.(restore-sql-reader-syntax-state)</pre>                                                                                                           |
| See also    | <code>disable-sql-reader-syntax</code><br><code>enable-sql-reader-syntax</code><br><code>locally-enable-sql-reader-syntax</code><br><code>restore-sql-reader-syntax-state</code>                                                        |

## **locally-enable-sql-reader-syntax** *Function*

|             |                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------|
| Summary     | Turns on square bracket syntax and does not change syntax state.                                                         |
| Package     | <code>sql</code>                                                                                                         |
| Signature   | <code>locally-enable-sql-reader-syntax</code>                                                                            |
| Arguments   | None.                                                                                                                    |
| Values      | None.                                                                                                                    |
| Description | The function <code>locally-enable-sql-reader-syntax</code> turns on square bracket syntax and does not change the syntax |

state. This ensures that `restore-sql-reader-syntax-state` restores the current enable/disable state.

**Example** The intended use of `locally-enable-sql-reader-syntax` is in a file:

```
#.(locally-enable-sql-reader-syntax)
<code using [...] syntax>
#. (restore-sql-reader-syntax-state)
```

## loop Macro

**Summary** Extends `loop` to provide a clause for iterating over query results.

**Package** `common-lisp`

**Signature** `loop {for|as} var [type-spec] being {the|each}
{records|record} {in|of} query-expression [not-inside-
transaction not-inside-transaction] [get-all get-all] => result`

**Arguments** `var` A variable.

`query-expression` A SQL query statement or a `prepared-
statement` containing a query.

`not-inside-transaction`

A generalized boolean.

`get-all` A generalized boolean.

**Values** `result` A `loop` return value.

**Description** The Common Lisp `loop` macro has been extended with a clause for iterating over query results. This extension is available only when Common SQL has been loaded. For a full description of the rest of the Common Lisp `loop` facility, including the possible return values, see the ANSI Common Lisp specification.

Each iteration of the loop assigns the next record of the table to the variable `var`. The record is represented in Lisp as a list. Destructuring can be used in `var` to bind variables to specific attributes of the records resulting from *query-expression*. In conjunction with the panoply of existing clauses available from the `loop` macro, the new iteration clause provides an integrated report generation facility.

The additional loop keywords `not-inside-transaction` and `get-all` may be useful when fetching many records through a connection with `database-type :mysql`. See the section “Special considerations for iteration functions and macros” on page 375 for details.

**Example** This extended `loop` example performs the following on each record returned as a result of a query: bind `name` to the query result, find the salary (if any) from an associated hash-table, increment a count for salaries greater than 20000, accumulate the salary, and print the details. Finally, it prints the average salary.

```
(loop
  for (name) being each record in
  [select [ename] :from [emp]]
  as salary = (gethash name *salary-table*)
  initially (format t "~&~20A~10D" 'name 'salary)
  when (and salary (> salary 20000))
  count salary into salaries
  and sum salary into total
  and do (format t "~&~20A~10D" name salary)
  else
  do (format t "~&~20A~10A" name "N/A")
  finally
  (format t "~2&Av Salary: ~10D" (/ total salaries)))
```

| <b>map-query</b> |                                                                                                                                                                                                                                                                                                                                           |
| Summary          | Returns the results of mapping a function across a SQL query statement.                                                                                                                                                                                                                                                                   |
| Package          | <code>sql</code>                                                                                                                                                                                                                                                                                                                          |
| Signature        | <code>map-query output-type-spec function query-exp &amp;key database not-inside-transaction get-all =&gt; result</code>                                                                                                                                                                                                                  |
| Arguments        | <p><i>output-type-spec</i> The output type specification.</p> <p><i>function</i> A function.</p> <p><i>query-exp</i> A SQL query or a <code>prepared-statement</code> containing a query.</p> <p><i>database</i> A database.</p> <p><i>not-inside-transaction</i> A generalized boolean.</p> <p><i>get-all</i> A generalized boolean.</p> |
| Values           | <i>result</i> A sequence of type <i>output-type-spec</i> containing the results of the map function.                                                                                                                                                                                                                                      |
| Description      | The function <code>map-query</code> returns the result of mapping <i>function</i> across the results of <i>query-exp</i> . The <i>output-type-spec</i> argument specifies the type of the result sequence as per the Common Lisp <code>map</code> function.                                                                               |

The default value of *database* is **\*default-database\***.

*not-inside-transaction* and *get-all* may be useful when fetching many records through a connection with *database-type* **:mysql**. Both of these arguments have default value **nil**. See the section “Special considerations for iteration functions and macros” on page 375 for details.

**Example** This example binds `name` to each name in the employee table and prints it.

```
(map-query
  nil
  #'(lambda (name) (print name))
  [select [ename] :from [emp] :flatp t])
```

## **\*mysql-library-directories\*** *Variable*

**Package** `sql`

**Initial value** `nil`

**Description** The variable **\*mysql-library-directories\*** helps Lisp-Works for Windows to locate the MySQL library for use with *database-type* **:mysql**. It specifies a directory or a list of directories in which to search for the MySQL library. If the value is a directory pathname designator then it is passed to `directory`. If the value is a list of directory pathname designators then each item is

passed to `directory`. The collected results are the list of directories to search in.

|                     |                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes               | The default value <code>nil</code> causes the system to use <code>*mysql-library-sub-directories*</code> to construct the search path. With the default installation of MySQL this copes better with 64-bit/32-bit mixing on the same machine. When <code>*mysql-library-directories*</code> is non- <code>nil</code> , it overrides <code>*mysql-library-sub-directories*</code> . |
| Compatibility notes | In LispWorks 6.0 <code>*mysql-library-directories*</code> has initial value <code>"C:\\Program Files\\MySQL\\MySQL*\\bin"</code> .<br>In LispWorks 6.1 and later, <code>*mysql-library-directories*</code> has initial value <code>nil</code> so the search path is constructed using <code>*mysql-library-sub-directories*</code> .                                                |
| See also            | <code>*mysql-library-path*</code><br><code>*mysql-library-sub-directories*</code>                                                                                                                                                                                                                                                                                                   |

## **\*mysql-library-path\*** Variable

|               |                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package       | <code>sql</code>                                                                                                                                                                                                          |
| Initial value | On Microsoft Windows:<br><br><code>"libmysql.dll"</code><br><br>On other platforms with pthreads:<br><br><code>"-lmysqlclient_r"</code><br><br>On other platforms without pthreads:<br><br><code>"-lmysqlclient"</code>   |
| Description   | The variable <code>*mysql-library-path*</code> helps the system to locate the MySQL library for use with <i>database-type</i> <code>:mysql</code> . It specifies the library name, and can also be set to a full path. If |

it is not a name, the system searches the standard library locations.

You can override the value of **\*mysql-library-path\*** by setting the environment variable `LW_MYSQL_LIBRARY`.

See also      **\*mysql-library-directories\***

**\*mysql-library-sub-directories\***                          *Variable*

Package      `sql`

Initial value      `"MySQL\\MySQL*\\bin"`

Description      The variable **\*mysql-library-sub-directories\*** helps LispWorks for Windows to locate the MySQL library for use with *database-type :mysql*.

It specifies a directory in which to search for the MySQL library, as a sub-directory of the appropriate Program Files directory. On a 32-bit machine that normally means `C:\\Program Files\\`, while on a 64-bit machine it normally means `C:\\Program Files\\` for 64-bit programs and `C:\\Program Files (x86)\\` for 32-bit programs.

The value must be a pathname designator. It is merged with the Program Files directory yielding a path (for example `"C:\\Program Files\\MySQL\\MySQL*\\bin"`) which is then passed to `directory`. The result is a list of directories that are used to search for the MySQL library.

The default value matches the default MySQL installation.

If **\*mysql-library-directories\*** is non-nil, it overrides **\*mysql-library-sub-directories\***.

Note that this default will match any MySQL release, so if you need to be sure to match a specific MySQL release, you

need to change the value of `*mysql-library-sub-directories*` such that it matches only that particular release.

| Description                   | <p>The function <code>ora-lob-append</code> appends the contents of the LOB pointed to by <code>src-lob-locator</code> to the end of LOB pointed by <code>dest-lob-locator</code>. The source and destination LOBs must be of the same internal LOB type, that is, either both BLOB or both CLOB/NCLOB.</p> <p>If an error occurs and <code>errorp</code> is true, an error is signaled. If <code>errorp</code> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <code>errorp</code> is <code>nil</code>.</p> <p><code>ora-lob-append</code> is applicable to internal LOBs only.</p> |                              |                |                               |                |                     |                        |
| Notes                         | <ol style="list-style-type: none"> <li>1. <code>ora-lob-append</code> is a direct call OCILobAppend.</li> <li>2. <code>ora-lob-append</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.</li> </ol>                                                                                                                                                                                                                                                                                                                                                      |                              |                |                               |                |                     |                        |

|           |                                                                                  | <i>Function</i>        |
|-----------|----------------------------------------------------------------------------------|------------------------|
| Summary   | Returns the database character set identifier of a LOB.                          |                        |
| Package   | <code>sql</code>                                                                 |                        |
| Signature | <code>ora-lob-char-set-id lob-locator &amp;key errorp =&gt; db-charset-id</code> |                        |
| Arguments | <i>lob-locator</i>                                                               | A LOB locator.         |
|           | <i>errorp</i>                                                                    | A generalized boolean. |

| Description         | <p>The function <b>ora-lob-copy</b> copies part of the LOB pointed to by <i>src-lob-locator</i> into the LOB pointed to by <i>dest-lob-locator</i>. The details of the operation are determined by <i>amount</i>, <i>src-offset</i> and <i>dest-offset</i>. These numbers are in characters for CLOB/NCLOB and bytes for BLOB, and the offsets start from 1. The part of the source LOB from offset <i>src-offset</i> of length <i>amount</i> is copied into the destination LOB at offset <i>dest-offset</i>. The default value of <i>dest-offset</i> is 1 and the default value of <i>src-offset</i> is 1.</p> <p>The destination LOB is extended if needed. If the <i>dest-offset</i> is beyond the end of the destination LOB, the gap between the</p> |

*This chapter applies to the Enterprise Edition only*

end and *dest-offset* is erased, that is, filled with 0 for BLOBs or spaces for CLOBs.

Both LOBs must be internal LOBs, and they must be of the same type, that is, either both BLOB or both CLOB/NCLOB.

**ora-lob-append** is applicable to internal LOBs only.

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

Notes

1. This is a direct call OCILobCopy.
2. This function is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

## ora-lob-create-empty

## *Function*

Summary      Creates an empty LOB.

Package      **sql**

Signature      **ora-lob-create-empty &key db type => lob-locator**

Arguments      **db**      A database.

**type**      A Lisp object.

Values      **lob-locator**      A LOB locator.

Description      The function **ora-lob-create-empty** creates an empty LOB object and returns a LOB locator for it.

If *type* is `:lob` then `ora-lob-create-empty` creates a LOB of type BLOB/CLOB. If *type* is any other value, it creates a file LOB. The default value of *type* is `:lob`.

Empty LOBs can be put in the database by passing them to `insert-records` or `update-records`. However, the preferred approach is to use the Oracle SQL function `EMPTY_BLOB` as described in the section “Inserting empty LOBs” on page 380.

The default value of *db* is the value of `*default-database*`.

| Values      | <i>pointer</i>                                                                                                                                           | A foreign pointer of type <b>p-oci-env</b> . |
| Description | The function <b>ora-lob-env-handle</b> returns a foreign pointer to the environment handle of the LOB underlying <i>lob-locator</i> .                    |                                              |
| Notes       | <b>ora-lob-env-handle</b> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information. |                                              |

## ora-lob-erase Function

|           |                                                                             |                         |
|-----------|-----------------------------------------------------------------------------|-------------------------|
| Summary   | Erases part of an internal LOB.                                             |                         |
| Package   | <b>sql</b>                                                                  |                         |
| Signature | <b>ora-lob-erase lob-locator offset amount &amp;key errorp =&gt; erased</b> |                         |
| Arguments | <i>lob-locator</i>                                                          | A LOB locator.          |
|           | <i>offset</i>                                                               | A non-negative integer. |
|           | <i>amount</i>                                                               | A non-negative integer. |

*This chapter applies to the Enterprise Edition only*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                         |

| Values      | <i>erased</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A non-negative integer.                                                                                                                                                                                                                                 |
| Description | The function <b>ora-lob-erase</b> erases part of the LOB pointed to by <i>lob-locator</i> . That is, it fills part of the LOB with 0 for BLOBs or spaces for CLOBs.<br><br>The operation starts from offset <i>offset</i> into the LOB and erases <i>amount</i> of data in the LOB, or to the end of the LOB. Note that the offset starts from 1, and that <i>offset</i> and <i>amount</i> are in characters for CLOBs and bytes for BLOB.<br><br>Erasing does not extend beyond the end of the LOB. The return value <i>erased</i> is the number of characters or bytes erased. <i>erased</i> will be smaller than <i>amount</i> if the sum of <i>offset</i> and <i>amount</i> is greater than the length of the LOB.<br><br><b>ora-lob-erase</b> is applicable to internal LOBs only.<br><br>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <b>sql-database-error</b> . The default value of <i>errorp</i> is <b>nil</b> . |                                                                                                                                                                                                                                                         |
| Notes       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <ol style="list-style-type: none"><li>1. ## **ora-lob-file-exists**                                          *Function*

Summary      The predicate for whether a LOB file exists.

Package      `sql`

Signature      `ora-lob-file-exists lob-locator &key errorp => result`

Arguments      *lob-locator*      A LOB locator.

*errorp*      A generalized boolean.

Values      *result*      A boolean.

Description      The function `ora-lob-file-exists` returns `t` if the file associated with the LOB exists. This function is applicable only to file LOBs (CFILE or BFILE).

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type `sql-database-error`. The default value of *errorp* is `nil`.

- Notes
1. This is a direct call to OCILobFileExists.
  2. `ora-lob-file-exists` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

|             | <i>Function</i>                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------|
| Summary     | Opens a file LOB.                                                                                     |
| Package     | <b>sql</b>                                                                                            |
| Signature   | <b>ora-lob-file-open</b> <i>file-lob-locator</i> & <b>key</b> <i>errorp</i>                           |
| Arguments   | <i>file-lob-locator</i> A file LOB locator.<br><i>errorp</i> A generalized boolean.                   |
| Description | The function <b>ora-lob-file-open</b> opens the file that <i>file-lob-locator</i> is associated with. |

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

- Notes
1. This is a direct call to OCILobFileOpen.
  2. **ora-lob-file-open** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.
- See also      **ora-lob-file-close**

## **ora-lob-file-set-name** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Sets the name of a file LOB.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Package     | <b>sql</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Signature   | <b>ora-lob-file-set-name</b> <i>file-lob-locator</i> <i>dir-alias</i> <i>name</i> & <i>key</i><br><i>errorp</i>                                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <i>file-lob-locator</i> A file LOB locator.<br><i>dir-alias</i> A string or <b>nil</b> .<br><i>name</i> A string or <b>nil</b> .<br><i>errorp</i> A generalized boolean.                                                                                                                                                                                                                                                                                     |
| Description | <p>The function <b>ora-lob-file-set-name</b> sets the directory alias and the name of the file LOB pointed to by <i>file-lob-locator</i>.</p> <p>If <i>dir-alias</i> is a string it should be of length no greater than 30. If it is <b>nil</b> then the directory alias of the file LOB is not changed.</p> <p>If <i>name</i> is a string it should be of length no greater than 255. If it is <b>nil</b> then the name of the file LOB is not changed.</p> |

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

- Notes
1. This is a direct call to OCILobFileSetAlias.
  2. **ora-lob-file-set-name** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

| Description                 | <p>The function <b>ora-lob-flush-buffer</b> flushes the buffer that is used by the Oracle client.</p> <p>If <i>free-buffer</i> is true, it also frees the buffer. The default value of <i>free-buffer</i> is <b>nil</b>.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <b>sql-database-error</b>. The default value of <i>errorp</i> is <b>nil</b>.</p> |                    |                |                    |                        |               |                        |

| Signature           | <b>ora-lob-free lob-locator</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Arguments           | <b>lob-locator</b> A LOB locator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description         | <p>The function <b>ora-lob-free</b> frees the LOB locator <i>lob-locator</i>. If <i>lob-locator</i> was retrieved inside an iteration macro or function (that is, one of <b>map-query</b>, <b>do-query</b>, <b>simple-do-query</b> and <b>loop</b>), it is freed before the next record is fetched, or when terminating the iteration for the last record.</p> <p>LOB locators which were retrieved by <b>select</b> or <b>query</b>, or were created by the user by <b>ora-lob-assign</b> or <b>ora-lob-create-empty</b> are freed automatically when the database connection is closed by a call to <b>disconnect</b>.</p> <p>If you create many LOB locators without closing the connection, it is useful to free them by calling <b>ora-lob-free</b>, to free the resources that are associated with them.</p> <p>Freeing a LOB locator does not affect the underlying LOB. In particular, after modifications to the LOB there is no <b>roll-back</b> even if there was not yet a <b>commit</b>.</p> |
| Notes               | <b>ora-lob-free</b> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|             | <i>eof-or-error-p</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A boolean or an error object.                |
| Description | <p>The function <code>ora-lab-get-buffer</code> gets a buffer for efficient I/O with foreign functions.</p> <p>If <i>for-writing</i> is <code>nil</code>, then <code>ora-lab-get-buffer</code> fills an internal buffer and returns three values: <i>amount/size</i> is how much it filled, <i>foreign-buffer</i> points to the actual buffer, and <i>eof-or-error-p</i> is the return value from the call to <code>ora-lab-read-foreign-buffer</code>. The offset <i>offset</i> is passed directly <code>ora-lab-read-foreign-buffer</code>.</p> <p>If <i>for-writing</i> is true, then <code>ora-lab-get-buffer</code> returns two values: <i>amount/size</i> is the size of the foreign buffer and <i>foreign-buffer</i> points to the actual buffer, which then can be passed to <code>ora-lab-write-foreign-buffer</code>.</p> <p>The default value of <i>for-writing</i> is <code>nil</code>.</p> <p>The buffer that is used by <code>ora-lab-get-buffer</code> is always the same for the LOB locator, it is used by <code>ora-lab-read-buffer</code> and <code>ora-lab-write-buffer</code>, and is freed automatically when the LOB locator is freed. Thus until you finish with the buffer, you cannot use <code>ora-lab-read-buffer</code> or <code>ora-lab-write-buffer</code> or call <code>ora-lab-get-buffer</code> again or free the LOB locator.</p> |                                              |

Notes      **ora-lob-get-buffer** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

Example    This first example illustrates reading using the buffer obtained by **ora-lob-get-buffer**. You have a foreign function:

```
my_chunk_processor(char *data, int size)
```

with this FLI definition:

```
(fli:define-foreign-function my_chunk_processor
  ((data :pointer)
   (size :int)))
```

You can pass all the data from the LOB locator to this function. Assuming no other function reads from it, it will start from the beginning.

```
(loop
  (multiple-value-bind (amount buffer eof-or-error-p)
    (ora-lob-get-buffer lob)
    (when (zerop amount) (return))
    (my_chunk_processor buffer amount)))
```

This second example illustrates writing with the buffer obtained by **ora-lob-get-buffer**. You have a foreign function that fills a buffer with data, and you want to write it to a LOB. First you should lock the record, and if required trim the LOB locator.

```
(multiple-value-bind (size buffer)
  (ora-lob-get-buffer lob-locator
    :for-writing t
    ;; start at the beginning
    :offset 1)
  (loop (let ((amount (my-fill-buffer buffer size)))
    (when (zerop amount) (return))
    (ora-lob-write-foreign-buffer
     lob-locator nil
     amount buffer size))))
```

## **ora-lob-internal-lob-p**

## *Function*

|                    |                                                                                                                                                                           |                    |                |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----------------|
| Summary            | The predicate for internal LOBs.                                                                                                                                          |                    |                |
| Package            | <code>sql</code>                                                                                                                                                          |                    |                |
| Signature          | <code>ora-lob-internal-lob-p lob-locator =&gt; result</code>                                                                                                              |                    |                |
| Arguments          | <table><tr><td><i>lob-locator</i></td><td>A LOB locator.</td></tr></table>                                                                                                | <i>lob-locator</i> | A LOB locator. |
| <i>lob-locator</i> | A LOB locator.                                                                                                                                                            |                    |                |
| Values             | <table><tr><td><i>result</i></td><td>A boolean.</td></tr></table>                                                                                                         | <i>result</i>      | A boolean.     |
| <i>result</i>      | A boolean.                                                                                                                                                                |                    |                |
| Description        | The function <code>ora-lob-internal-lob-p</code> returns <code>t</code> if <i>lob-locator</i> is internal (BLOB, CLOB, or NCLOB). Otherwise it returns <code>nil</code> . |                    |                |

**Notes** **ora-lob-internal-lob-p** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

## ora-lob-is-equal *Function*

**Summary** The comparison function for LOB locators.

**Package** **sql**

**Signature** **ora-lob-is-equal lob-locator1 lob-locator2 => result**

**Arguments** *lob-locator1* A LOB locator.  
*lob-locator2* A LOB locator.

**Values** *result* A boolean.

**Description** The function **ora-lob-is-equal** returns **t** if *lob-locator1* and *lob-locator2* point to the same LOB object.

**Notes**

1. This is a direct call to OCILobIsEqual.
2. **ora-lob-is-equal** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

## ora-lob-is-open *Function*

**Summary** The predicate for whether a LOB locator is opened.

**Package** **sql**

**Signature** **ora-lob-is-open lob-locator &key errorp => result**

**Arguments** *lob-locator* A LOB locator.

*This chapter applies to the Enterprise Edition only*

| Summary     | The predicate for whether a LOB is temporary.                                                                                                                                 |                        |
| Package     | <b>sql</b>                                                                                                                                                                    |                        |
| Signature   | <b>ora-lab-is-temporary lob-locator &amp;key errorp =&gt; result</b>                                                                                                          |                        |
| Arguments   | <i>lob-locator</i>                                                                                                                                                            | A LOB locator.         |
|             | <i>errorp</i>                                                                                                                                                                 | A generalized boolean. |
| Values      | <i>result</i>                                                                                                                                                                 | A boolean.             |
| Description | The function <b>ora-lab-is-temporary</b> returns <b>t</b> if the LOB underlying <i>lob-locator</i> is temporary, that is, it was created by <b>ora-lab-create-temporary</b> . |                        |

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

- Notes
1. This is a direct call to OCILobIsTemporary.
  2. **ora-lob-is-temporary** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

|             | <i>src-lob-file</i>                                                                                                                                                                                                                              | A file LOB locator.      |
|             | <i>amount</i>                                                                                                                                                                                                                                    | A non-negative integer.  |
|             | <i>src-offset</i>                                                                                                                                                                                                                                | A non-negative integer.  |
|             | <i>dest-offset</i>                                                                                                                                                                                                                               | A non-negative integer.  |
|             | <i>errorp</i>                                                                                                                                                                                                                                    | A generalized boolean.   |
| Description | <p>The function <b>ora-lob-load-from-file</b> loads the data from the <i>src-lob-file</i> into the destination LOB pointed to by <i>dest-lob-locator</i>.</p> <p>The source LOB must be a BFILE and the destination must be an internal LOB.</p> |                          |

*This chapter applies to the Enterprise Edition only*

The details of the operation are determined by *amount*, *src-offset* and *dest-offset*. *amount* and *dest-offset* are in characters for CLOB/NCLOB and are in bytes for BLOB. *src-offset* is in bytes. The offsets start from 1. The default value of *dest-offset* is 1 and the default value of *src-offset* is 1.

No conversion is performed by `ora-lob-load-from-file`, so if the destination is a CLOB/NCLOB, the source must already be in the right format.

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type `sql-database-error`. The default value of *errorp* is `nil`.

- Notes
1. This is a direct call to OCILobLoadFromFile. The Oracle documentation is ambiguous on whether it is mandatory to open the source LOB before calling this function.
  2. `ora-lob-load-from-file` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                       | A boolean.             |
| Description | <p>The function <b>ora-lob-locator-is-init</b> returns <b>t</b> if the LOB locator <i>lob-locator</i> is initialized.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <b>sql-database-error</b>. The default value of <i>errorp</i> is <b>nil</b>.</p> |                        |
| Notes       | <ol style="list-style-type: none"> <li>1. This is a direct call to <b>OCILobIsInit</b>.</li> <li>2. <b>ora-lob-locator-is-init</b> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 380 for more information.</li> </ol>                                                                        |                        |

## ora-lob-open *Function*

|         |              |
|---------|--------------|
| Summary | Opens a LOB. |
|---------|--------------|

*This chapter applies to the Enterprise Edition only*

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                          |                |                     |                        |

| Description              | <p>The function <code>ora-lob-open</code> opens the LOB pointed to by <code>lob-locator</code>, which can be an internal LOB or a file LOB.</p> <p>Opening the LOB creates a transaction, so any updates associated with modifying the LOB are delayed until the <code>ora-lob-close</code> call. This saves round-trips and avoids extra work on the server side. However it is not mandatory to use <code>ora-lob-open</code>.</p> <p>Calls to <code>ora-lob-open</code> must be strictly paired to calls to <code>ora-lob-close</code>, and the latter must be called before a call to <code>commit</code>. It is also an error to call <code>ora-lob-open</code> on a server LOB object that is already open, even if it has been opened via a different LOB locator.</p> <p>If an error occurs and <code>errorp</code> is true, an error is signaled. If <code>errorp</code> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <code>errorp</code> is <code>nil</code>.</p> |                          |                |                     |                        |

|             | <i>eof-or-error-p</i> | A boolean or an error object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |                       | <p>The function <code>ora-lob-read-buffer</code> reads into <i>buffer</i> from the LOB pointed to by <i>lob-locator</i>.</p> <p><i>offset</i> specifies the offset to start reading from. It starts with 1, and specifies characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE. If <i>offset</i> is <code>nil</code> then the offset after the end of the previous read operation is used (write operations are ignored). This is especially useful for reading linearly from the LOB.</p> <p><i>amount</i> is the amount to read, in characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE.</p> <p>The element type of <i>buffer</i> should match the element type of the LOB locator (see <code>ora-lob-element-type</code>). For this comparison <code>(unsigned-byte 8)</code> and <code>base-char</code> are considered as the same.</p> <p>If the buffer <i>buffer</i> is not static, there is some additional overhead. For small amounts of data, this is probably insignificant.</p> |

*buffer-offset* specifies where to put the data. It is an offset in bytes from the beginning of the buffer. The default value of *buffer-offset* is 0.

*csid* specifies what Character Set ID the data in the target buffer should be. It defaults to the CSID of the LOB pointed to by *lob-locator*.

The return value *amount-read* is the number of elements (characters or bytes) that were read.

If the return value *eof-or-error-p* is *nil* then there is still more to read. If *eof-or-error-p* is *t* then it read to the end of the LOB. If an error occurred then *eof-or-error-p* is an error object.

- Notes
1. This is a direct call to OCILobRead, without callback.
  2. *ora-lob-read-buffer* is available only when the "oracle" module is loaded. See the section “Oracle LOB interface” on page 380 for more information.

- Example
- This example sequentially reads the LOB data into a string, starting from offset 10000. It calls a processing function on each chunk of data and then reads in the next chunk starting from where the previous read ended.

```
(let ((my-buffer (make-string 1000
                               :element-type 'base-char))
      (offset 10000))
  (loop
    (let ((nread
           (ora-lob-read-buffer lob-locator
                                 offset
                                 1000
                                 my-buffer)))
      (when (zerop nread) ; end of the LOB
        (return))
      (my-processing-function my-buffer nread)
      (setq offset nil))) ; so next time it continues
                           ; from where it finished
```

| Description        | <p>The function <code>ora-lob-read-into-plain-file</code> writes the contents of a LOB into a file.</p> <p><i>file-name</i> specifies the file to write, which should be a standard file. The file is always opened in a binary mode, so if the LOB is a CLOB, the file will be generated in the right format when reading it from the LOB.</p> <p><i>offset</i> is the offset into the LOB from where to start reading. It starts from 1, counts characters in a CLOB, and if it is <code>nil</code> then the operation starts from the end of the previous read operation. The default value of <i>offset</i> is <code>nil</code>.</p> <p><i>file-offset</i> specifies the offset into the file to start the operation from. If <i>file-offset</i> is <code>nil</code> then it starts writing at the start of the file. The default value of <i>file-offset</i> is <code>nil</code>.</p> <p><i>if-exists</i> is passed to <code>open</code> when opening the file, with the standard Common Lisp meaning. The default value of <i>if-exists</i> is <code>:error</code>.</p> |                    |                |                  |                        |               |                                               |                    |                                               |                  |                                 |

| Values      | <i>amount-read</i>                                                                                                                                                                                                                                                                      | A non-negative integer.                      |
|             | <i>eof-or-error-p</i>                                                                                                                                                                                                                                                                   | A boolean or an error object.                |
| Description | <p>The function <code>ora-lob-read-foreign-buffer</code> reads from the LOB pointed to by <i>lob-locator</i> into the foreign buffer <i>foreign-buffer</i>.<br/>This is just like <code>ora-lob-read-buffer</code> except that it reads from the LOB locator into a foreign buffer.</p> |                                              |

*foreign-buffer* is a FLI pointer to a buffer, which must be of size at least *buffer-length*.

|          |                                                                                                                                                                                                                                                                                           |

| Description        | <p>The function <code>ora-lob-trim</code> trims the LOB pointed to by <i>lob-locator</i> to a new size <i>new-size</i>, which must be smaller than its current size.</p> <p>Note that <i>new-size</i> is in characters for CLOBs and bytes for BLOBs.</p> <p><code>ora-lob-trim</code> is applicable to internal LOBs only.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |                    |                |                 |                         |               |                        |

|             | <i>eof-or-error-p</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A boolean or an error object.                                             |
| Description | The function <code>ora-lob-write-buffer</code> writes to the LOB pointed to by <i>lob-locator</i> from <i>buffer</i> .<br><br><i>offset</i> specifies the offset to start writing to. It starts with 1, and specifies characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE. If <i>offset</i> is <code>nil</code> then the offset after the end of the previous write operation is used (read operations are ignored). This is especially useful for writing linearly to the LOB.<br><br><i>amount</i> is the amount to write, in characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE.<br><br>The element type of <i>buffer</i> should match the element type of the LOB locator (see <code>ora-lob-element-type</code> ). For this comparison <code>(unsigned-byte 8)</code> and <code>base-char</code> are considered as the same.<br><br>If the buffer <i>buffer</i> is not static, there is some additional overhead. For small amounts of data, this is probably insignificant.<br><br><i>buffer-offset</i> specifies where in the buffer to start writing data from. It is an offset in bytes from the beginning of the buffer. The default value of <i>buffer-offset</i> is 0. |                                                                           |

*This chapter applies to the Enterprise Edition only*

*csid* specifies what Character Set ID the data in the source buffer should be. It defaults to the CSID of the LOB pointed to by *lob-locator*.

The return value *amount-written* is the number of elements (characters or bytes) that were written

The LOB is extended as required.

If the return value *eof-or-error-p* is `nil` then there is still more to write. If *eof-or-error-p* is `t` then it wrote to the end of the LOB. If an error occurred then *eof-or-error-p* is an error object.

- Notes
1. The record from which the LOB came must be locked. See the section “Locking” on page 382.
  2. `ora-lob-write-buffer` is a direct call to `OCILobWrite`, without callback.
  3. `ora-lob-write-buffer` is available only when the “oracle” module is loaded. See the section “Oracle LOB interface” on page 380 for more information.

## **ora-lob-write-from-plain-file** *Function*

- Summary      Writes the contents of a file into a LOB.

- Package      `sql`

- Signature      `ora-lob-write-from-plain-file lob-locator file-name &key offset file-offset if-does-not-exist`

- Arguments      *lob-locator*      A LOB locator.

- file-name*      A pathname designator.

- offset*      A non-negative integer, or `nil`.

|             | <i>if-does-not-exist</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A keyword or <code>nil</code> .               |
| Description | <p>The function <code>ora-lob-write-from-plain-file</code> writes the contents of a file into a LOB.</p> <p><i>file-name</i> specifies the file to read, which should be a standard file. The file is always opened in a binary mode, so if the LOB is a CLOB, the file must be in the right format when writing it into the LOB.</p> <p><i>offset</i> is the offset into the LOB from where to start writing. It starts from 1, counts characters in a CLOB, and if it is <code>nil</code> then the operation starts from the end of the previous write operation. The default value of <i>offset</i> is <code>nil</code>.</p> <p><i>file-offset</i> specifies the offset into the file to start the operation from. If <i>file-offset</i> is <code>nil</code> then it starts reading at the start of the file. The default value of <i>file-offset</i> is <code>nil</code>.</p> <p><i>if-does-not-exist</i> is passed to <code>open</code> when opening the file, with the standard Common Lisp meaning. The default value of <i>if-does-not-exist</i> is <code>:error</code>.</p> |                                               |
| Notes       | <p><code>ora-lob-write-from-plain-file</code> is available only when the "oracle" module is loaded. | <code>sql-exp</code>        | A SQL expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| <code>database</code>       | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| <code>variable-types</code> | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| <code>count</code>          | A non-negative integer or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| <code>flatp</code>          | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| <code>result-types</code>   | A list of symbols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| Values                      | <code>prepared-statement</code><br>A <code>prepared-statement</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |
| Description                 | The function <code>prepare-statement</code> returns a <code>prepared-statement</code> object for the SQL statement <code>sql-exp</code> in the database <code>database</code> . <code>sql-exp</code> can contain bind-variables in the form <code>:n</code> where <code>n</code> is a positive integer.<br><br>If <code>database</code> is supplied, then the <code>prepared-statement</code> is associated with the database. Otherwise <code>set-prepared-statement-variables</code> will do the association even if it is called without a database. |                      |                   |                       |             |                             |         |                    |                                              |                    |            |                           |                    |

If *variable-types* is supplied, then it should be a list containing a keyword element for each bind-variable in *sql-exp*. It has an effect in two cases:

- **:string** forces the variable to be passed to the database as a string. That may be useful if you have numeric values in Lisp which are stored as strings in the database.
- **:date** cause an integer to be interpreted as a universal-time and be converted properly to an Oracle date. This is not supported on SQLite databases, which do not support date fields.

If *variable-types* is not supplied, then the types will be chosen dynamically from the values passed to **set-prepared-statement-variables**.

If *count* is supplied, then it should equal the maximum number of bind-variables in the *sql-exp*. If *count* is not supplied, then it is calculated from *sql-exp*.

*flatp* and *result-types* are interpreted the same as in **select**.

The result of **prepare-statement** is a **prepared-statement**. This can be used by calling **set-prepared-statement-variables** to actually bind the variables, and then use one of the querying or executing interfaces that take a SQL expression argument: **execute-command**, **query**, **do-query**, **simple-do-query**, **map-query** and the **loop for...being each record** construct.

A **prepared-statement** that is associated with a database should be destroyed (by **destroy-prepared-statement**) before the database is closed, otherwise it may leak memory.

Notes      *sql-exp* can be any valid SQL expression, not only a query.

Examples    Create a **prepared-statement** for a SQL expression:

```
(setq ps
      (sql:prepare-statement
        "insert into TABLETWO values(:1, :2)"))
```

*This chapter applies to the Enterprise Edition only*

Then insert records into TABLETWO (which has two columns) by repeatedly doing:

```
(sql:set-prepared-statement-variables  
  ps  
  (list value1 value2))  
  
(sql:execute-command ps))
```

## **prepared-statement**

*System Class*

Summary      A class of objects prepared SQL statements.

Package      `sql`

Signature      `prepared-statement`

Description      Each instance of the system class `prepared-statement` represents a SQL statement prepared by `prepare-statement`.

See also      `prepare-statement`

## **print-query**

*Function*

Summary      Prints a tabulated version of records resulting from a query.

Package      `sql`

| Description | <p>The function <code>print-query</code> takes a symbolic SQL query expression and formatting information and prints onto <i>stream</i> a table containing the results of the query.</p> <p>A list of strings to use as column headings is given by <i>titles</i>, which has a default value of <code>nil</code>.</p> <p>The <i>formats</i> argument is a list of format strings used to print each attribute, and has a default value of <code>t</code>, which means that <code>-A</code> or <code>-VA</code> are used if sizes are provided or computed.</p> <p>The field sizes are given by <i>sizes</i>. It has a default value of <code>t</code>, which specifies that minimum sizes are computed.</p> <p>The output stream is given by <i>stream</i>, which has a default value of <code>t</code>. This specifies that <code>*standard-output*</code> is used.</p> |
| Examples    | The following call prints out two even columns of names and salaries:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Summary     | Queries a database and returns a list of values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature   | <code>query sql-exp &amp;key database result-types flatp =&gt; result-list, field-names</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Arguments   | <p><i>sql-exp</i>      A SQL query statement or a <b>prepared-statement</b> containing a query.</p> <p><i>database</i>      A database.</p> <p><i>result-types</i>      A list of symbols.</p> <p><i>flatp</i>      A boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <p><i>result-list</i>      A list of values.</p> <p><i>field-names</i>      A list of strings.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | <p>The function <b>query</b> is the basic SQL query function. It queries the database specified by <i>database</i> with a SQL query statement given by <i>sql-exp</i>.</p> <p>The argument <i>database</i> defaults to <b>*default-database*</b>.</p> <p><i>result-types</i> is a list of symbols such as <code>:string</code> and <code>:integer</code>, one for each field in the query, which are used to specify the types to return. It is ignored if <i>sql-exp</i> is a <b>prepared-statement</b>.</p> <p><i>flatp</i> is used as in <b>select</b> and is ignored if <i>sql-exp</i> is a <b>prepared-statement</b>.</p> <p><i>result-list</i> is a list of values as per <b>select</b>, and <i>field-names</i> is a list of field names selected in <i>sql-exp</i>.</p> |
| Example     | The following two queries, on a table whose second column contains dates that we want to return as strings, are equivalent:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

```
(sql:query "select * from some_table"
           :result-types '(nil :string))

(sql:query [select [*]
            :from [some_table]
            :result-types '(nil :string)])
```

| Values           | <code>success</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |
| Description      | <p>The function <code>reconnect</code> reconnects <code>database</code> to its underlying RDBMS. If successful, <code>success</code> is <code>t</code> and the variable <code>*default-database*</code> is set to the newly reconnected database.</p> <p>The default value for <code>database</code> is <code>*default-database*</code>. If <code>database</code> is a database object, then it is used directly. Otherwise, the list of connected databases is searched to find</p> |                 |

*This chapter applies to the Enterprise Edition only*

one with database as its connection specifications (see `connect`). If no such database is found, then if `error` and `database` are both non-nil an error is signaled, otherwise `reconnect` returns `nil`.

`force` controls whether an error should be signaled if the existing database connection cannot be closed. When non-nil (this is the default value) the connection is closed without error checking. When `force` is `nil`, an error is signaled if the database connection has been lost.

|          |                                                                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>force</code> non-nil might result in a memory leak if the database driver fails to release its memory (some drivers do not allow the connection to be closed if the underlying RDBMS is not responding). |

## **restore-sql-reader-syntax-state** *Function*

|             |                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Sets the enable/disable square bracket syntax state to reflect the last call to either <code>disable-sql-reader-syntax</code> or <code>enable-sql-reader-syntax</code> .                                           |
| Package     | <code>sql</code>                                                                                                                                                                                                   |
| Signature   | <code>restore-sql-reader-syntax-state</code>                                                                                                                                                                       |
| Arguments   | None.                                                                                                                                                                                                              |
| Values      | None.                                                                                                                                                                                                              |
| Description | The function <code>restore-sql-reader-syntax-state</code> sets the enable/disable state of the square bracket syntax to reflect the last call to either <code>enable-sql-reader-syntax</code> or <code>dis-</code> |

**able-sql-reader-syntax.** The default state of the square bracket syntax is disabled.

**rollback** *Function*

Summary Rolls back changes made to a database since the last commit.

Package `sql`

Signature `rollback &key database => nil`

Arguments `database` A database.

Values `nil`

Description The function `rollback` rolls back changes made in `database` since the last commit, that is, changes made since the last commit are not recorded. The argument `database` defaults to **\*default-database\***.

| Description | <p>The function <code>select</code> selects data from <i>database</i>, which has a default value of <code>*default-database*</code>, given the constraints specified by the rest of the arguments. It returns a list of objects as specified by <i>selections</i>. By default, the objects will each be represented as lists of attribute values.</p> <p>The argument <i>selections</i> consists either of database identifiers, type-modified database identifiers or literal strings.</p> <p>A type-modified database identifier is an expression such as <code>[foo :string]</code> which means that the values in column <code>foo</code> are returned as Lisp strings. This syntax can be used to force</p> |                                           |

values in time/date fields to be returned as strings (see below for an example). It can also be used to affect the value returned from MySQL, using the keywords mentioned in the section “Using MySQL” on page 373. It can also be used to return `lob-stream` objects for queries on Oracle LOB columns, using an expression like `[foo :input-stream]` or `[foo :output-stream]`

*result-types* is used when *selections* is `*` or `[*]`. It should be a list of symbols such as `:string` and `:integer`, one for each field in the table being selected in order to specify the types to return. Note that, for specific selections, the result type can be specified by using a type-modified identifier as described above. However, you cannot use *result-types* to modify the type returned from a time/date field.

*flatp*, which has a default value of `nil`, specifies if full bracketed results should be returned for each matched entry. If *flatp* is `nil`, the results are returned as a list of lists. If *flatp* is `t`, the results are returned as elements of a list, only if there is only one result per row. See the examples section for an example of the use of *flatp*.

The arguments *all*, *set-operation*, *distinct*, *from*, *where*, *group-by*, *having* and *order-by* have the same function as the equivalent SQL expression.

*for-update* is used to specify the FOR UPDATE clause in a select statement which is used by Oracle to lock the selected records. If *for-update* is `t` then a plain "FOR UPDATE" clause is generated. This locks all retrieved records, waiting for the locks to become available. If *for-update* is `:nowait` then a "FOR UPDATE NOWAIT" clause is generated. This locks all the retrieved records, or otherwise returns with error ora-00054 which causes Lisp to signal a `sql-temporary-error`. If *for-update* is a string then it should specify a column to be locked and a clause "FOR UPDATE OF *for-update*" is generated. If *for-update* is a list then the elements of the list should be strings each specifying a column to be locked,

except that the last element of the list may be `:nowait`. A clause locking multiple columns is generated, waiting for the locks according to whether `:nowait` was supplied. For an example see the section “Locking” on page 382.

The function `select` is common across both the functional and object-oriented SQL interfaces. If `selections` refers to View Classes then the `select` operation becomes object-oriented. This means that `select` returns a list of View Class instances, and `slot-value` becomes a valid SQL operator for use within the `where` clause.

In the View Class case, a second equivalent `select` call will return the same View Class instance objects. If `refresh` is true, then existing instances are updated if necessary, and in this case you might need to extend the hook `instance-refreshed`. Any join slots defined using `retrieval :deferred` will be recomputed the next time they are accessed. The default value of `refresh` is `nil`.

SQL expressions used in the `select` function are specified using the square bracket syntax, once this syntax has been enabled using `enable-sql-reader-syntax`.

SQL expressions used in the `select` function are commonly specified using the “Symbolic SQL syntax” on page 358. Note that you need to enable it by using `enable-sql-reader-syntax` or `locally-enable-sql-reader-syntax` so they can be read correctly. An expression can also be made dynamically by using `sql-expression`.

## Examples

The following is a potential query and result:

```
(select [person_id] [surname] :from [person])  
=> ((111 "Brown") (112 "Jones") (113 "Smith"))
```

In the next example, the `flatp` argument is set to `t`, and the result is a simple list of surname values:

```
(select [surname] :from [person] :flatp t)
```

```
=> ("Brown" "Jones" "Smith")
```

In this example data in the attribute `largenum`, which is of a vendor-specific large numeric type, is returned to Lisp as strings:

```
(sql:select [largenum :string] :from [my-table])
```

In this example the second column of `some_table` is a date that we want to return as a string:

```
(sql:select [*]
            :from [some_table]
            :result-types '(nil :string))
```

In this example we see that a time/date field value is returned as an integer. We then use Common Lisp to decode that universal time, and finally query the database again, forcing the return value to be a string formatted by the database:

```
CL-USER 219 > (sql:select [MyDate]
                           :from [MyTable]
                           :flatp t)
(3313785600)
("MYDATE")

CL-USER 220 > (decode-universal-time (car *))
0
0
0
0
4
1
2005
1
NIL
0

CL-USER 221 > (sql:select [MyDate :string]
                           :from [MyTable]
                           :flatp t)
("2005-01-04 00:00:00")
("MYDATE")
```

*This chapter applies to the Enterprise Edition only*

Finally this code gets the first 1 KB of data from the first LOB returned by a query on an Oracle table containing a column of type LOB:

```
(let* ((array
        (make-array 1024
                   :element-type '(unsigned-byte 8)))
       (lobs (sql:select [my-lob-column :input-stream]
                         :from [mytable] :flatp t)))
      (read-sequence array (car lobs)))
```

## set-prepared-statement-variables

## *Function*

|             |                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Sets the values of the bind variables in a <code>prepared-statement</code> .                                                                                    |
| Package     | <code>sql</code>                                                                                                                                                |
| Signature   | <code>set-prepared-statement-variables <i>prepared-statement</i> &amp;key <i>database</i> <i>values</i> =&gt; <i>prepared-statement</i></code>                  |
| Arguments   | <code>prepared-statement</code><br>A <code>prepared-statement</code> .<br><code>database</code> A database or <code>nil</code> .<br><code>values</code> A list. |
| Description | The function <code>set-prepared-statement-variables</code> sets the values of the bind variables in the <code>prepared-statement</code> pre-                    |

*pared-statement* to the objects in the list given by *values*. The length of *values* must equal the number of bind-variables in *prepared-statement* (that is, the supplied or computed count in `prepare-statement`). If *database* is supplied, then *prepared-statement* is (re)associated with that database.

If *database* is not supplied and the statement is not associated with a database yet, `set-prepared-statement-variables` associates it with the default database `*default-database*`. If the statement was already associated and *database* is `nil`, the association does not change.

`set-prepared-statement-variables` returns the prepared-statement.

## simple-do-query *Macro*

Summary      Repeatedly binds a variable to the results of a query, optionally binds another variable to the column names, and executes a body of code within the scope of these bindings.

Package      `sql`

Signature     `simple-do-query (values-list query &key names-list database not-inside-transaction get-all) &body body =>`

Arguments    `values-list`      A variable.

`query`        A database query or a `prepared-statement` containing a query.

`names-list`    A variable, or `nil`.

`database`     A database.

`not-inside-transaction`

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Generates SQL from a set of expressions.                                                                                                                                                                                                                                                                                                |
| Package     | <b>sql</b>                                                                                                                                                                                                                                                                                                                              |
| Signature   | <b>sql &amp;rest args =&gt; sql-expression</b>                                                                                                                                                                                                                                                                                          |
| Arguments   | <b>args</b> A set of expressions.                                                                                                                                                                                                                                                                                                       |
| Values      | <b>sql-expression</b> A SQL expression.                                                                                                                                                                                                                                                                                                 |
| Description | The function <b>sql</b> generates SQL from a set of expressions given by <b>args</b> . Each argument to <b>sql</b> is translated into SQL and then the <b>args</b> are concatenated with a single space between each pair. The rules for translation into SQL, based on the type of each individual argument <b>x</b> , are as follows: |
|             | <pre>string =&gt; (format nil "'~A'" x) nil =&gt; "NULL" symbol =&gt; (symbol-name x) number =&gt; (princ-to-string x) list =&gt; (format nil "~{~A~,~}") (mapcar #'sql x)) vector =&gt; (format nil "~{~A~,~}" (map 'list #'sql x)) sql-expression =&gt; x Any other symbol =&gt; error</pre>                                          |

| Description | <p>The condition class <code>sql-database-error</code> is used to signal errors in the database interface that Common SQL uses.</p> <p><code>sql-error-error-id</code> returns the primary error identifier. On ODBC the value is a string. On Oracle it is some number, the "v2 return code" in the Cursor Data Area.</p> <p><code>sql-error-secondary-error-id</code> returns the secondary error identifier. On ODBC this is the error code from the underlying database. On Oracle that is the "v4 return code" (also known as "return code") in the Cursor Data Area, which is the useful code.</p> <p><code>sql-error-database-message</code> is a string (maybe <code>nil</code>) that came back from the foreign code.</p> |
| Notes       | ODBC drivers for Oracle return the "v4 return code" as the underlying database code. Therefore in the event of an error on connection to an Oracle database, <code>sql-error-secondary-error-id</code> always returns the "v4 return code" whether the connection is through ODBC.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Description                 | The amount to enlarge static memory by before loading database code. This is an optimization of static memory fragmentation, useful for some databases. It is ignored when loading Oracle. |                 |

Notes      **\*sql-enlarge-static\*** is applicable in LispWorks for SPARC Solaris.

| Description                  | <p>The function <code>sql-expression</code> generates a SQL expression from the supplied keywords. The result <code>sql-expression</code> is of type <code>sql-expression-object</code>, which specifies some SQL that can be used inside other calls to <code>sql-expression</code>, a "[...]" syntax expression or as an argument to the Common SQL functions. <code>sql-expression</code> matches what the read-time "[...]" syntax generates for identifiers (see “Enclosing database identifiers” on page 359), but can be used at run time.</p> <p>If <code>string</code> is non-nil, it must be the only keyword and specifies the entire SQL, directly without any further processing.</p> |                     |           |                    |                                                        |                        |                                                        |                    |                                                        |                    |           |                   |            |                          |           |                              |          |

If *attribute* is supplied, it specifies an attribute (column) name, and the resulting SQL is an attribute named by *attribute*. It can optionally be qualified by *table* and *owner* (the schema that owns the table), so the attribute name becomes *table.attribute* if *owner* is `nil` or *owner.table.attribute* if *owner* is non-nil. If *table* is `nil` the attribute name is not qualified.

If *table* is supplied, it specifies a table name. If *attribute* is supplied too, it qualifies the attribute as in the previous paragraph, otherwise the resulting SQL is a table name. It can be optionally qualified by *owner*, which specifies *owner.table* as the table name.

*owner* can be non-nil only when *table* is supplied, and qualifies *table* as described above. It specifies the schema to which the table belongs.

If *alias* is non-nil it specifies an alias, which added to the SQL after the attribute name if *attribute* is supplied or after the table name otherwise.

*type* can be non-nil only if *attribute* is supplied, and specifies the expected type of the attribute. This does not affect the SQL, but tells the querying interface (`select`, `query`) what type the value should be. It is useful when the attribute is used in the selection list of a query (see “Specifying the type of retrieved values.” on page 362).

If *parameter-index* is non-nil, it must be the only keyword, and `sql-expression` generates a bind-variable in the SQL. This can be used in an expression that is passed to `prepare-statement` and then later bound by `set-prepared-statement-variables`.

If *n-qualified* is non-nil, it must be the only keyword, and the value is used as-is as an N syntax string. This is required for passing non-ASCII string to Microsoft SQL Server (via ODBC), but does not work on SQLite or Microsoft Access.

*This chapter applies to the Enterprise Edition only*

```
(sql-expression :n-qualified "aa")
=>
#<SQL: "N'aa'">

(sql-expression :string      "aa")
=>
#<SQL: "aa">
```

See “SQL string literals” on page 366 for discussion of N syntax strings.

**Examples** Define a function that queries for the value of a supplied attribute in a supplied table using a supplied type:

```
(defun query-attribute (table-name attribute-name type)
  (let* ((table-arg
          (sql-expression
            :table table-name))
         (selection-arg
          (sql-expression
            :attribute attribute-name
            :type type)))
    (select selection-arg :from table-arg)))
```

## sql-expression-object

## System Class

**Summary** A class of objects representing some SQL.

**Package** [sql](#)

**Superclasses** [t](#)

**Description** Each instance of the system class [sql-expression-object](#) represents a SQL expression. They can be used inside another

instance of `sql-expression-object`, in a "[...]" syntax expression or as arguments to the Common SQL functions. They are created by the "[...]" syntax (see “Enclosing database identifiers” on page 359) or dynamically by `sql-expression` or `string-prefix-with-n-if-needed`.

**sql-fatal-error** *Condition*

Package      `sql`

Superclasses    `sql-connection-error`

Description     The condition class `sql-fatal-error` is used to signal errors that mean the connection can no longer be used.

**sqlite-blob** *System Class*

Summary      A class of objects that provide read/write access to a BLOB or TEXT field in a SQLite database.

Package      `sql`

Superclasses    `t`

Description     An instance of the system class `sqlite-blob` provides direct read/write access to a BLOB or TEXT field in a SQLite database. See `replace-from-sqlite-blob` for details.

| Arguments                       | <code>database</code> A SQLite database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values                          | <code>rowid</code> An integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description                     | The function <code>sqlite-last-insert-rowid</code> returns the ROWID of the last row that was inserted in <code>database</code> , or 0 if none.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Notes                           | <code>sqlite-last-insert-rowid</code> is not thread-safe, and you will need to ensure that no other thread inserts rows into <code>database</code> in parallel to the insertion of the row and calling <code>sqlite-last-insert-rowid</code> .<br><br>The result <code>rowid</code> is useful when you want to later access a BLOB in the row using <code>sqlite-open-blob</code> .<br><br>ROWIDs in SQLite are described in the SQLite documentation: "ROWIDs and the INTEGER PRIMARY KEY" in "CREATE TABLE"<br><a href="https://www.sqlite.org/lang_createtable.html#rowid">https://www.sqlite.org/lang_createtable.html#rowid</a> .<br><br>Because <code>sqlite-last-insert-rowid</code> is called on the database connection, any row insertion into <code>database</code> affects it, even if it is not in the same table or even not the same file (if another file is attached to the connection using the "ATTACH DATABASE" statement). Therefore, there must not be another insertion into <code>database</code> in parallel to the sequence of insertion and calling <code>sqlite-last-insert-rowid</code> .<br><br>These restrictions mirror the underlying limitation of the C function <code>sqlite3_last_insert_rowid</code> . |

*Functions*

Summary      Read/write access to a BLOB or TEXT field in a SQLite database.

Package      `sql`

Signature      `sqlite-open-blob table-name column-name rowid &key database owner read-only => sqlite-blob`

`sqlite-close-blob sqlite-blob => boolean`

`sqlite-blob-p object => boolean`

`sqlite-blob-length sqlite-blob => length`

`replace-from-sqlite-blob binary-array sqlite-blob &key array-start array-end blob-start blob-end => binary-array`

`replace-into-sqlite-blob sqlite-blob binary-array &key blob-start blob-end array-start array-end => sqlite-blob`

`sqlite-reopen-blob sqlite-blob rowid`

Arguments      `table-name, column-name`

                  Strings.

`rowid`        An integer.

`database`     A SQLite database.

`owner`        A string.

*This chapter applies to the Enterprise Edition only*

|             | <i>binary-array</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | An array with integer or float element type, or a <b>base-string</b> , or a <b>bmp-string</b> . |
| Description | Instances of the system class <b>sqlite-blob</b> allow reading and writing from/to BLOB or TEXT fields in a SQLite database. It corresponds to the C structure <b>sqlite3_blob</b> (see "A Handle To An Open BLOB" in the SQLite documentation, <a href="https://www.sqlite.org/c3ref/blob.html">https://www.sqlite.org/c3ref/blob.html</a> ).<br><br>The function <b>sqlite-open-blob</b> creates an object of type <b>sqlite-blob</b> , which can be used to access the data in a specific column and row of a SQLite database table, as specified by <i>database</i> , <i>owner</i> , <i>table-name</i> , <i>column-name</i> and <i>rowid</i> . <i>owner</i> specifies the schema-name (which defaults to " <b>main</b> "), and thus allows access to attached databases. <i>table-name</i> and <i>column-name</i> specify the table and column. <i>rowid</i> specifies the row where the value is. For documentation about <i>rowid</i> , see "ROWIDs and the INTEGER PRIMARY KEY" in "CREATE TABLE" in the SQLite documentation ( <a href="https://www.sqlite.org/lang_createtable.html#rowid">https://www.sqlite.org/lang_createtable.html#rowid</a> ), and |                                                                                                 |

also the notes below. `read-only` (which defaults to `nil`) specifies whether the result `sqlite-blob` is read-only or not.

The function `sqlite-blob-p` returns true if `object` is of type `sqlite-blob` and false otherwise.

The function `sqlite-blob-length` returns the length of `sqlite-blob` in bytes. Note that there is no way to change the length.

The functions `replace-from-sqlite-blob` and `replace-into-sqlite-blob` are used to copy from/to `sqlite-blob`, similar to `replace` or `fli:replace-foreign-array`. `binary-array` must be a binary array, which means an array of element type `base-char`, `bmp-char`, `single-float`, `double-float`, `(unsigned-byte bit-size)` or `(signed-byte bit-size)`, where `bit-size` is one of 8, 16, 32 or (64-bit LispWorks only) 64. Note that `simple-string` is not regarded as a binary array, but `bmp-string` and `base-string` are. The length of `sqlite-blob` in elements is the length in bytes, as returned by the function `sqlite-blob-length`, truncated by the number bytes per element in `binary-array`. The values of `array-start`, `array-end`, `blob-start` and `blob-end` are all in elements (rather than bytes).

The function `replace-from-sqlite-blob` replaces the elements of `binary-array` between `array-start` and `array-end` by the elements of `sqlite-blob` between `blob-start` and `blob-end`. The function `replace-into-sqlite-blob` replaces in the other direction.

`blob-start` and `array-start` default to 0, `array-end` defaults to `nil`, meaning the length of `binary-array`, and `blob-end` defaults to `nil`, meaning the length of `sqlite-blob` in elements. When supplied, `array-start` must be a non-negative integer and not bigger than the length of `binary-array`, `array-end` must be not smaller than `array-start` and not bigger than the length of `binary-array`, `blob-start` must be a non-negative integer and not bigger than the length of `sqlite-blob` in elements, and `blob-end` must be not smaller than `blob-start` and not bigger than the length of `sqlite-blob` in elements. The number of elements cop-

ied is the smaller of the difference between *blob-start* and *blob-end*, and the difference between *array-start* and *array-end*.

`replace-from-sqlite-blob` and `replace-into-sqlite-blob` return their first argument.

The function `sqlite-close-blob` closes *sqlite-blob* and returns `t` if it closed, or `nil` if *sqlite-blob* was already closed.

The function `sqlite-reopen-blob` changes *sqlite-blob* to refer to a field in another row. In effect it closes *sqlite-blob* and reopens it with a different *rowid* but otherwise the same arguments as the `sqlite-open-blob` call that opened it.

#### Notes

You can obtain a ROWID by using `rowid` in the selection list of a query. For example, the following query returns a list of ROWIDs for records that match *somecondition* in the table `SomeTable` (in `*default-database*`):

```
(sql:select [rowid] :from [SomeTable]
            :where somecondition
            :flatp t)
```

The ROWID may be also be the value of a primary key in the table, as described in the SQLite documentation: "ROWIDs and the INTEGER PRIMARY KEY" in "CREATE TABLE"  
[https://www.sqlite.org/lang\\_createtable.html#rowid](https://www.sqlite.org/lang_createtable.html#rowid).

It is also possible to find the ROWID of the last inserted row by `sqlite-last-insert-rowid`.

If the row where the field that *sqlite-blob* is accessing is modified, further access to *sqlite-blob* by `replace-into-sqlite-blob` or `replace-from-sqlite-blob` signals an error (of type `sql-user-error`). That is because SQLite itself does not allow further access. As a result, using `sqlite-blob` is not thread-safe, and you need be sure that no other code is trying to modify the same row while *sqlite-blob* is open.

`sqlite-open-blob` may fail for various reasons. When this happens, LispWorks retrieves the error message using the C function `sqlite3_errmsg`, which is not thread-safe (an

apparent misdesign of SQLite). As a result, you will get a misleading error message in very rare occasions, if another thread executing on the same database got an error in parallel. However, the error number, is always correct and its values are documented in the SQLite documentation "Result Code Meanings" <https://www.sqlite.org/rescode.html#error>.

Leaving a `sqlite-blob` opened is not only a resource leak, but also leaves some locks in the database connection that prevents some operations in the future (dropping the table or disconnecting the database for example). Therefore, you should close a `sqlite-blob` as soon as possible. We recommend using `with-sqlite-blob` to open and close the `sqlite-blob` when possible.

**sqlite-raw-blob****System Class**

**Summary** A class of objects that allow efficient access to a SQLite BLOB.

**Package** `sql`

**Superclasses** `t`

**Description** An instance of the system class `sqlite-raw-blob` allows you to efficiently access SQLite BLOB objects inside the dynamic extent of the Common SQL iterative querying interface.

See `copy-from-sqlite-raw-blob` for details.

*Functions*

Summary      Efficient access to a SQLite BLOB field in a query.

Package      `sql`

Signature      `sqlite-raw-blob-p object => boolean`  
`sqlite-raw-blob-valid-p sqlite-raw-blob => boolean`  
`sqlite-raw-blob-length sqlite-raw-blob => length`  
`sqlite-raw-blob-ref sqlite-raw-blob index &optional foreign-element-type => value`  
`copy-from-sqlite-raw-blob sqlite-raw-blob &key start end element-type => binary-array`  
`replace-from-sqlite-raw-blob binary-array sqlite-raw-blob &key array-start array-end blob-start blob-end => binary-array`

Arguments      *object*      Any Lisp object.

*sqlite-raw-blob*      An object of type `sqlite-raw-blob`.

*index*      An integer.

*foreign-element-type*

                  A foreign element type.

*start, end*      Bounding index designators of *sqlite-raw-blob*.

*element-type*      A Lisp element type for a binary array.

*binary-array*      An array with integer or float element type or a `base-string` or a `bmp-string`.

|             | <i>binary-array</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | An array with integer or float element type or a <b>base-string</b> or a <b>bmp-string</b> . |
| Description | <p>The <b>sqlite-raw-blob</b> interface allows a flexible and more efficient way to read from a SQLite BLOB object inside the dynamic extent of a Common SQL the iterative querying interface. The iterative querying interfaces include <b>map-query</b>, <b>do-query</b>, <b>simple-do-query</b>, <b>loop</b> with <b>each record</b>, but does not include <b>select</b> and <b>query</b>.</p> <p>Note that <b>sqlite-raw-blob</b> corresponds to the result of the C function <b>sqlite3_column_blob</b>. You can read data from a BLOB using <b>sqlite-raw-blob</b>, but cannot modify it. For an interface that corresponds to the C structure <b>sqlite3_blob</b>, see <b>sqlite-blob</b>.</p> <p>You receive a <b>sqlite-raw-blob</b> object as the value from the query for fields where you specify the type as <b>:blob</b>. This object is associated with a SQLite BLOB corresponding to the value of this field in the current row. For example, you can print the size (in bytes) of all the fields in the DataPointsColumn in SomeTable using this code:</p> |                                                                                              |

*This chapter applies to the Enterprise Edition only*

```
(do-query
  ((raw-data-points)
   [select [DataPointsColumn :blob]
          :from [Sometable]])
  (print (sqlite-raw-blob-length raw-data-points)))
```

The function `sqlite-raw-blob-p` returns true if *object* is of type `sqlite-raw-blob` and false otherwise.

The function `sqlite-raw-blob-length` returns the length in bytes of the BLOB associated with `sqlite-raw-blob`.

For the functions `sqlite-raw-blob-ref`, `copy-from-sqlite-raw-blob` and `replace-from-sqlite-raw-blob`, `sqlite-raw-blob` can be regarded as a handle to a foreign array of bytes, whose length in bytes as returned by `sqlite-raw-blob-length`. When the element type argument (*foreign-element-type* or *element-type*) requires more than one byte, then the length of `sqlite-raw-blob` in elements is the length in bytes truncated by the number of bytes per element.

The function `sqlite-raw-blob-ref` is analogous to `fli:dereference`. The element type is specified by *foreign-element-type*, which defaults to `(:unsigned :byte)`. *index* must be a non-negative integer and smaller than the length of `sqlite-raw-blob` in elements. `sqlite-raw-blob-ref` returns *value* in the same way that `(fli:dereference pointer-to-the-blob-data :index index :type foreign-element-type)` would return it, if *pointer-to-the-blob-data* pointed to a foreign array with the same contents as `sqlite-raw-blob`.

The function `copy-from-sqlite-raw-blob` returns a Lisp array of element type *element-type* containing the elements of `sqlite-raw-blob` bounded by *start* and *end* (in . *start* and *end* specify the start and the end indices in elements (rather than bytes) into `sqlite-raw-blob`. *start* defaults to 0, and *end* to `nil`, meaning the length of `sqlite-raw-blob` in elements. When supplied, *start* must be a non-negative integer and not bigger than the length of `sqlite-raw-blob` in elements, and *end* must be not smaller than *start* and not bigger than the length of `sqlite-raw-blob` in elements. *element-type* specifies the Lisp type of

*binary-array*. It is upgraded by `upgraded-array-element-type`, and the result must be one of:

- `base-char`
- `bmp-char`
- `single-float`
- `double-float`
- `(unsigned-byte 8)`
- `(unsigned-byte 16)`
- `(unsigned-byte 32)`
- `(unsigned-byte 64)` (64-bit LispWorks only)
- `(signed-byte 8)`
- `(signed-byte 16)`
- `(signed-byte 32)`
- `(signed-byte 64)` (64-bit LispWorks only)

The function `replace-from-sqlite-raw-blob` is analogous to `fli:replace-foreign-array`. It replaces the elements of *binary-array*, bounded by `array-start` and `array-end`, by the elements of *sqlite-raw-blob*, bounded by `blob-start` and `blob-end` (all in `elements`). *binary-array* must be a binary array, which means an array with one of the element types listed in the previous paragraph. `array-start` and `blob-start` default to 0, `array-end` defaults to `nil`, meaning the length of *binary-array*, and `blob-end` defaults to `nil`, meaning the length of *sqlite-raw-blob* in `elements`. When supplied, `array-start` must be a non-negative integer and not bigger than the length of *binary-array*, `array-end` must be not smaller than `array-start` and not bigger than the length of *binary-array*, `blob-start` must be a non-negative integer and not bigger than the length of *sqlite-raw-blob* in `elements`, and `blob-end` must be not smaller than `blob-start` and not bigger than the length of *sqlite-raw-blob* in `elements`. The number of elements copied is the smaller of

the difference between `array-start` and `array-end`, and the difference between `blob-start` and `blob-end`. `replace-from-sqlite-raw-blob` returns *binary-array*.

A `sqlite-raw-blob` object is valid only inside the dynamic extent of the code that receives it from the iterative querying interface function or macro. Note that the `sqlite-raw-blob` is already invalid in the next iteration of the same operation. Trying to read data from an invalid `sqlite-raw-blob` using one of `sqlite-raw-blob-ref`, `copy-from-sqlite-raw-blob` or `replace-from-sqlite-raw-blob` signals an error (of type `sql-user-error`). `sqlite-raw-blob-length` still returns the correct value for an invalid `sqlite-raw-blob`. `sqlite-raw-blob-valid-p` can be used to check if a `sqlite-raw-blob` is valid, but should be rarely useful.

| Package       | <code>sql</code>                                                                                                                                                                                                                                                                                                                    |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                    |
| Description   | Holds a pathname or list of libraries to override default database library loading. The value should be a pathname or a list.<br><br>If its value is a pathname, it is prepended to a list of relative pathnames in the same manner that the supplied environment variable (for example <code>ORACLE_HOME</code> ) would be. If its |

value is a list, then it is assumed to be a complete list of full library names which are loaded verbatim.

Notes      \***sql-libraries\*** is applicable only on Unix/Linux.

### **\*sql-loading-verbose\***                          *Variable*

Package      **sql**

Initial value      **nil**

Description      The variable **\*sql-loading-verbose\*** controls the verbosity of messages while loading the database libraries.

Notes      \***sql-loading-verbose\*** is applicable only on Unix.

### **sql-operation**                          *Function*

Summary      Generates a SQL statement from an operator and arguments.

Package      **sql**

Signature      **sql-operation op &rest args => sql-result**  
**sql-operation sql-function name &rest args => sql-result**  
**sql-operation sql-operator inop1 left &rest rights => sql-result**  
**sql-operation sql-boolean-operator inop2 left &rest rights => sql-result**

Arguments      *op*                          An operator.

*args*                          A set of arguments for *op*.

*name*                          An arbitrary function.

*args*                          A set of arguments for *name*.

|-------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>inop1</i>      | An infix operator with non-boolean result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | <i>inop2</i>      | An infix operator that returns a boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | <i>left</i>       | Argument to be placed on the left of an infix operator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | <i>rights</i>     | Arguments to be placed on the right of an infix operator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      | <i>sql-result</i> | A SQL expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                   | <p>The function <b>sql-operation</b> takes an operator and its arguments, and returns a SQL expression.</p> <p><b>(sql-operation op args)</b></p> <p>is shorthand for</p> <p><b>(apply (sql-operator op) args).</b></p> <p>The pseudo operator <b>sql-function</b> allows an arbitrary function <i>name</i> to be passed. In this case, <i>name</i> is put in the SQL expression using <b>princ</b>, and <i>args</i> are given as arguments.</p> <p>The pseudo operators <b>sql-boolean-operator</b> and <b>sql-operator</b> generate SQL that calls an infix operator with <i>left</i> on the left and <i>rights</i> on the right separated by spaces. Use <b>sql-boolean-operator</b> for SQL infix operators that return a boolean and use <b>sql-operator</b> for any other SQL infix operator.</p> |
| Notes       |                   | The pseudo operator <b>sql-operator</b> should not be confused with the Common SQL function <b>sql-operator</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Example     |                   | The following code, uses <b>sql-operation</b> to produce a SQL expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

```
(sql-operation 'select
  (sql-expression :table 'foo :attribute 'bar)
  (sql-expression :attribute 'baz)
  :from (list
    (sql-expression :table 'foo)
    (sql-expression :table 'quux)))
:where
  (sql-operation 'or
    (sql-operation '>
      (sql-expression :attribute 'baz)
      3)
    (sql-operation 'like
      (sql-expression :table 'foo :attribute 'bar)
      "SU%")))
```

The following SQL expression is produced.

```
#<SQL-QUERY: "(SELECT FOO.BAR,BAZ FROM FOO,QUUX
  WHERE ((BAZ > 3) OR (FOO.BAR LIKE 'SU%')))">
```

The following code illustrates use of the pseudo operator `sql-function`:

```
(sql-operation 'sql-function "TO_DATE" "03/06/99"
  "mm/DD/RR")
```

The following SQL expression is produced.

```
#<SQL-VALUE-EXP "TO_DATE('03/06/99','mm/DD/RR')">
```

## **sql-recording-p** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                        |  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | A predicate for determining if SQL commands or results traffic is being recorded.                                                                                                                                                                                                                                                                                      |  |
| Package     | <b>sql</b>                                                                                                                                                                                                                                                                                                                                                             |  |
| Signature   | <b>sql-recording-p &amp;key type database =&gt; recording-p</b>                                                                                                                                                                                                                                                                                                        |  |
| Arguments   | <i>type</i> One of :commands or :results.<br><i>database</i> A database.                                                                                                                                                                                                                                                                                               |  |
| Values      | <i>recording-p</i> A boolean.                                                                                                                                                                                                                                                                                                                                          |  |
| Description | The function <b>sql-recording-p</b> returns <b>t</b> if <i>type</i> is :commands and SQL commands traffic is being recorded, or if <i>type</i> is :results and SQL results traffic is being recorded. Otherwise it returns <b>nil</b> .<br><br>The default value of <i>type</i> is :commands. The default value of <i>database</i> is the value of *default-database*. |  |

|----------------------------|-----------------|
| <b>start-sql-recording</b> | <i>Function</i> |
|----------------------------|-----------------|

Summary       Starts recording SQL commands or results traffic.

Package      **sql**

Signature     **start-sql-recording &key type database =>**

Arguments    **type**                  A keyword.

**database**              A database.

Values        None.

Description     The function **start-sql-recording** starts recording SQL traffic, potentially to multiple streams. The traffic recorded can be the commands, the results, or both commands and results.

By default the output appears only **\*standard-output\***. You can modify the broadcast list of recording streams using **add-sql-stream** and **delete-sql-stream**.

**type** is one of **:commands**, **:results** or **:both**. It determines whether SQL commands traffic, results traffic or both is recorded.

*This chapter applies to the Enterprise Edition only*

The default value of *type* is `:commands`. The default value for *database* is the value of `*default-database*`.

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Arguments   | <i>string</i>                                                                                                                                                                                                                                                                                                                                                                                                                  | A string.   |
|             | <i>database</i>                                                                                                                                                                                                                                                                                                                                                                                                                | A database. |
| Values      | <i>needs-n-prefix-p</i>                                                                                                                                                                                                                                                                                                                                                                                                        | A boolean.  |
| Description | The function <b>string-needs-n-prefix</b> returns true if <i>string</i> needs to be prefixed by N when passed to <i>database</i> (default <b>*default-database*</b> ).                                                                                                                                                                                                                                                         |             |
| Notes       | The function <b>string-prefix-with-n-if-needed</b> can be used to add the prefix if needed. The function <b>sql-expression</b> with <b>:n-qualified</b> can be used to unconditionally add the prefix.<br><br>At the time of writing, the prefix is required only when <i>database</i> is a connection to Microsoft SQL Server, and <i>string</i> contains characters which are not recognized by the code page of the server. |             |

## **string-prefix-with-n-if-needed** *Function*

|           |                                                                                                   |                                              |
|-----------|---------------------------------------------------------------------------------------------------|----------------------------------------------|
| Summary   | Adds the N syntax to a string if needed.                                                          |                                              |
| Package   | <b>sql</b>                                                                                        |                                              |
| Signature | <b>string-prefix-with-n-if-needed</b> <i>string</i> & <b>key</b> <i>database</i> => <i>result</i> |                                              |
| Arguments | <i>string</i>                                                                                     | A string.                                    |
|           | <i>database</i>                                                                                   | A database.                                  |
| Values    | <i>result</i>                                                                                     | A string or a <b>sql-expression-object</b> . |

|             |                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>string-prefix-with-n-if-needed</code> checks if <i>string</i> , when passed to <i>database</i> , needs to be prefixed by N. If the prefix is required, it returns a <code>sql-expression-object</code> with the string prefixed. Otherwise it returns <i>string</i> . |
| Notes       | <code>string-prefix-with-n-if-needed</code> is equivalent to:<br><br><code>(if (string-needs-n-prefix string :database database)       (sql-expression :n-qualified string)       string)</code>                                                                                         |
| See also    | “SQL string literals” on page 366<br><code>string-needs-n-prefix</code>                                                                                                                                                                                                                  |

|                 | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                       |              |                         |                 |             |              |                                                   |

## update-instance-from-records

## *Generic Function*

**Summary**      Updates a View Class instance.

## Package sq1

**Signature** `update-instance-from-records instance &key database => instance`

**Arguments**      *instance*      An instance of a View Class

*database* A database

**Values**      *instance*      The updated View Class instance.

**Description** The generic function `update-instance-from-records` updates the values in the slots of the View Class instance *instance* using the data in the database *database*.

*database* defaults to the database that *instance* is associated with, or the value of **\*default-database\***. If *instance* is associated with a database, then *database* must be that same database.

The argument *slot* is the CLOS slot name; the corresponding column names are derived from the View Class definition.

The update is not recursive on joins. Join slots (that is, slots with `:db-kind :join`) are updated, but the joined objects are not updated.

| <i>force-p</i>       | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                             |              |                                           |                |            |                   |                                                 |                |                                               |
| <i>class-name</i>    | The class of the objects, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                             |              |                                           |                |            |                   |                                                 |                |                                               |
| <i>max-len</i>       | A non-negative integer, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                             |              |                                           |                |            |                   |                                                 |                |                                               |
| Description          | <p>The function <code>update-objects-joins</code> updates the remote join slots, that is those slots defined without <code>:retrieval :immediate</code>.</p> <p>This is an optimization function which can improve the efficiency of an application by reducing the number of queries of the database. For each slot, it queries the database using the data from all the objects, and then assigns the appropriate value to each object.</p> <p><i>objects</i> is a list of database objects. If <i>class-name</i> is non-<code>nil</code>, then all the database objects are of this class. If <i>class-name</i> is <code>nil</code>, then all the database objects are of the class of the first database object in the list <i>objects</i>.</p> <p>If <i>objects</i> is <code>nil</code>, then <code>update-objects-joins</code> does nothing.</p> <p><i>class-name</i> specifies a class containing all the database objects in the list <i>objects</i>. If <i>class-name</i> is <code>nil</code> (the default) then the class of the first database object is used.</p> <p><i>slots</i> provides a list of the names of slots to update. Each of these slots should be a remote join slot (as defined above).</p> <p><i>slots</i> can also be <code>t</code>, meaning update all the remote join slots. The default value of <i>slots</i> is <code>t</code>.</p> |                |                             |              |                                           |                |            |                   |                                                 |                |                                               |

*This chapter applies to the Enterprise Edition only*

*force-p* controls whether to force the update of all values in the objects. If *force-p* is `nil`, then slots which are already are not updated. The default value of *force-p* is `t`.

*max-len*, if non-nil, is a maximum number of objects from which to use data in a single query. If the length of the list *objects* is greater than *max-len* then `update-objects-joins` performs multiple queries using the data from no more than *max-len* objects in each query. This is useful if the DBMS may reject large queries, but it will increase the number of queries and hence reduce overall performance to some extent. The default value of *max-len* is the value of the variable  
`*default-update-objects-max-len*`.

| Signature             |                   | <code>update-records table &amp;key attributes values av-pairs where database =&gt;</code> |
| Arguments             | <i>table</i>      | A database table.                                                                          |
|                       | <i>attributes</i> | A set of columns.                                                                          |
|                       | <i>values</i>     | A set of values.                                                                           |
|                       | <i>av-pairs</i>   | An association list alternative to <i>attributes</i> and <i>values</i> .                   |
|                       | <i>where</i>      | A condition.                                                                               |
|                       | <i>database</i>   | A database.                                                                                |
| Values                |                   | None.                                                                                      |

|             |                                                                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>update-records</code> changes the values of existing fields in <i>table</i> with columns specified by <i>attributes</i> and <i>values</i> (or <i>av-pairs</i> ) where the <i>where</i> condition is true. |

| Description     | <p>The generic function <code>update-records-from-instance</code> updates the records in <i>database</i> represented by <i>instance</i>. If the instance is already associated with a database, that database is used, and <i>database</i> is ignored. If <i>instance</i> is not yet associated with a database, a record is created for <i>instance</i> in the appropriate table of <i>database</i> and the instance becomes associated with that database.</p> <p><code>update-records-from-instance</code> only updates the records from the base slots of <i>instance</i> - it does not look at the join slots.</p> |                 |                              |                 |             |

*This chapter applies to the Enterprise Edition only*

## update-record-from-slot

## *Generic Function*

**Summary** Updates an individual data item from a slot.

## Package sq1

**Signature**      `update-record-from-slot instance slot &key database`

**Arguments**      *instance*      An instance of a View Class.

*slot* A slot.

*database* A database

Values      None.

**Description** The generic function `update-record-from-slot` updates an individual data item in the column represented by *slot*. The *database* is only used if *instance* is not yet associated with any database, in which case a record is created in *database*. Only *slot* is initialized in this case; other columns in the underlying database receive default values. The argument *slot* is the CLOS slot name; the corresponding column names are derived from the View Class definition.

| Values          | <i>instance</i> The updated View Class instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |                              |             |              |
| Description     | <p>The generic function <code>update-slot-from-record</code> updates the value in the slot <i>slot</i> of the View Class instance <i>instance</i> using the records in the database.</p> <p><i>instance</i> must be associated with a database.</p> <p>The argument <i>slot</i> is the CLOS slot name; the corresponding column names are derived from the View Class definition.</p> <p>The update is not recursive on joins. Join slots (that is, slots with <code>:db-kind :join</code>) are updated, but the joined objects are not updated.</p> |                 |                              |             |              |

### \*use-n-syntax-for-non-ascii-strings\* Variable

|               |                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Control whether the symbolic SQL syntax uses the N syntax for non-ASCII SQL string literals.                                                                                        |
| Package       | <code>sql</code>                                                                                                                                                                    |
| Initial Value | <code>nil</code>                                                                                                                                                                    |
| Description   | The variable <code>*use-n-syntax-for-non-ascii-strings*</code> controls whether SQL string literals containing non-ASCII characters are put into SQL expressions with the N syntax. |

*This chapter applies to the Enterprise Edition only*

When `*use-n-syntax-for-non-ascii-strings*` is `nil` (the default), all string literals are produced without the `N` syntax. When `*use-n-syntax-for-non-ascii-strings*` is `non-nil`, non-ASCII string literals are produced with the `N` syntax.

A non-ASCII string is any string that contains character codes out of the ASCII range 0 to 127.

For example:

```
(sql:sql-operation '= [name] "hhh<Greek>"')
=>
#<SQL-RELATIONAL-EXP "(NAME = 'hhh<Greek>')">

(let ((sql:*use-n-syntax-for-non-ascii-strings* t))
  (sql:sql-operation '= [name] "hh<Greek>"))
=>
#<SQL-RELATIONAL-EXP "(NAME = N'hh<Greek>')">
```

For the symbolic SQL "[...]" syntax , the effect of `*use-n-syntax-for-non-ascii-strings*` occurs at macro expansion time. Therefore, if you use the symbolic SQL syntax and want to make of use `*use-n-syntax-for-non-ascii-strings*`, then you need to set it before compiling your code.

See “SQL string literals” on page 366 for details.

Notes Microsoft SQL Server is currently the only SQL backend that requires the `N` syntax.

`*use-n-syntax-for-non-ascii-strings*` does not affect what `sql-expression` with `:string` does.

| Description | <p>The macro <code>with-sqlite-blob</code> opens a BLOB by calling <code>sqlite-open-blob</code> with <i>database</i>, <i>owner</i>, <i>table-name</i>, <i>column-name</i>, <i>rowid</i> and <i>read-only</i>, binds <i>blob-var</i> to the resulting <code>sqlite-blob</code>, and evaluates the forms in <i>body</i> (as an implicit <code>progn</code>) inside the binding and inside an <code>unwind-protect</code> that closes <i>blob-var</i> on exit.</p> <p>The return values of <code>with-sqlite-blob</code>, <i>results-of-body</i>, are whatever <i>body</i> returns.</p> |                                   |
| Notes       | <p>Because <code>with-sqlite-blob</code> guarantees to close the BLOB when it exits, you should use it in preference to calling <code>sqlite-open-blob</code> directly.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |                                   |

| <code>body</code>     | A set of Lisp expressions.                                                                                                                                                                                                                                                                                                                                                                                                     |                       |             |                   |                            |
| Values                | <code>results</code><br>The values returned by <code>body</code> .                                                                                                                                                                                                                                                                                                                                                             |                       |             |                   |                            |
| Description           | <p>The macro <code>with-transaction</code> executes <code>body</code> within a transaction for <code>database</code> (which defaults to <code>*default-database*</code>). The transaction is committed if the body finishes successfully (without aborting or throwing), otherwise the database is rolled back.</p> <p><code>with-transaction</code> returns the value or multiple values returned from <code>body</code>.</p> |                       |             |                   |                            |
| Example               | The following example shows how to use <code>with-transaction</code> to insert a new record, updates the department number of employees from 40 to 50, and removes employees whose salary is higher than 300,000. If an error occurs anywhere in the body and an <code>abort</code> or <code>throw</code> is executed, none of the updates are committed.                                                                      |                       |             |                   |                            |
|                       | <pre>(with-transaction   (insert-record :into [empl]                  :attributes '(x y z)                  :values '(a b c))   (update-records [emp]                  :attributes [dept]                  :values 50                  :where [= [dept] 40])   (delete-records :from [emp]                  :where [&gt; [salary] 300000]))</pre>                                                                              |                       |             |                   |                            |
| See also              | <code>commit</code><br><code>rollback</code>                                                                                                                                                                                                                                                                                                                                                                                   |                       |             |                   |                            |

## The STREAM Package

This chapter describes the symbols available in the `stream` package that provide users with the functionality to define their own streams for use by the standard I/O functions.

This is discussed in detail in Chapter 24, “User Defined Streams”.

| buffered-stream | <i>Class</i>                                                                                                               |
|-----------------|----------------------------------------------------------------------------------------------------------------------------|
| Summary         | A stream class giving access to stream buffers.                                                                            |
| Package         | <code>stream</code>                                                                                                        |
| Superclasses    | <code>fundamental-stream</code>                                                                                            |
| Subclasses      | <code>lob-stream</code><br><code>string-stream</code><br><code>socket-stream</code>                                        |
| Initargs        | <code>:direction</code> One of <code>:input</code> , <code>:output</code> or <code>:io</code> . This argument is required. |

**:element-type** One of **base-char**, **bmp-char**, **simple-char** or **character**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The class <b>buffered-stream</b> provides default methods for the majority of the functions in the User Defined Streams protocol. The default methods implement buffered I/O, requiring the user to define only the methods <b>stream-read-buffer</b>, <b>stream-write-buffer</b> and <b>stream-element-type</b> for each subclass of <b>buffered-stream</b>. You are at liberty to redefine other methods in subclasses as long as they obey the rules outlined here. For example it is usually desirable to implement methods on <b>stream-listen</b>, <b>stream-check-eof-no-hang</b> and <b>close</b> as well.</p> <p>The initargs are handled by the method <code>(method initialize-instance :after (buffered-stream))</code> as follows:</p> <p>Input and/or output buffers are created based on the value <i>direction</i>. There is no default value, and you must supply a value.</p> <p><i>element-type</i> determines the <b>stream-element-type</b> of the stream. The default is <b>base-char</b>. For binary streams, use <b>base-char</b>.</p> <p>All the methods in the User Defined Streams protocol are defined for <b>buffered-stream</b> as follows:</p> <ul style="list-style-type: none"> <li>• The methods on <b>stream-read-char</b>, <b>stream-read-line</b>, <b>stream-read-sequence</b>, <b>stream-unread-char</b>, <b>stream-read-char-no-hang</b>, <b>stream-clear-input</b> handle input from the buffer. They each call <b>stream-fill-buffer</b> to fill the empty buffer as required.</li> <li>• The methods on <b>stream-write-char</b>, <b>stream-write-string</b>, <b>stream-write-sequence</b>, <b>stream-clear-output</b>, <b>stream-finish-output</b>, <b>stream-force-output</b> and <b>stream-line-column</b> handle output to the buffer. They each call <b>stream-flush-buffer</b> to make the buffer empty as required.</li> </ul> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- There are `:around` methods on `stream-listen` and `close` which handle the buffer.
- The methods on `input-stream-p`, `output-stream-p` return the appropriate values based on the value of the `:direction` initarg.
- The `open-stream-p` method returns true if `close` has not been called.

Example See the extended example in

```
(example-edit-file "streams/buffered-stream")
```

## **fundamental-binary-input-stream** *Class*

Summary A stream class for binary input.

Package `stream`

Superclasses `fundamental-binary-stream`  
`fundamental-input-stream`

Subclasses None.

Description The class `fundamental-binary-input-stream` provides a class for generating customized binary input stream classes. A method for `stream-read-byte` should be provided when using this class.

See also      **`fundamental-binary-stream`**  
**`fundamental-input-stream`**  
**`stream-read-byte`**

## **`fundamental-binary-output-stream`** *Class*

Summary      A stream class for binary output.

Package      **`stream`**

Superclasses    **`fundamental-binary-stream`**  
**`fundamental-output-stream`**

Description     The class **`fundamental-binary-output-stream`** provides a class for generating customized binary output stream classes. A method for **`stream-write-byte`** should be provided.

See also      **`fundamental-binary-stream`**  
**`fundamental-output-stream`**  
**`stream-write-byte`**

## **`fundamental-binary-stream`** *Class*

Summary      A class for binary streams.

Package      **`stream`**

Superclasses    **`fundamental-stream`**

Subclasses     **`fundamental-binary-input-stream`**  
**`fundamental-binary-output-stream`**

Description     The class **`fundamental-binary-stream`** is the superclass of the binary input and output stream classes. A method for **`stream-element-type`** should be provided for concrete subclasses of this class.

See also      **fundamental-binary-input-stream**  
                **fundamental-binary-output-stream**  
                **fundamental-stream**  
                **stream-element-type**

## **fundamental-character-input-stream** *Class*

Summary      A class that should be included in stream classes for character input.

Package      **stream**

Superclasses      **fundamental-character-stream**  
                    **fundamental-input-stream**

Subclasses      None.

Description      The class **fundamental-character-input-stream** provides default methods for generic functions used for character input, and should therefore be included by stream classes concerned with character input. The user can provide methods for these generic functions specialized on the user-defined class. Methods for other generic functions must be provided by the user.

There is an example in “Defining a new stream class” on page 400.

| Summary      | A class that should be included in stream classes for character output.                                                                                                                                                                                                                                                                                                                                                                                       |
| Package      | <b>stream</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Superclasses | <b>fundamental-character-stream</b><br><b>fundamental-output-stream</b>                                                                                                                                                                                                                                                                                                                                                                                       |
| Subclasses   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description  | The class <b>fundamental-character-output-stream</b> provides default methods for generic functions used for character output, and should therefore be included by stream classes concerned with character output. The user can provide methods for these generic functions specialized on the user-defined class. Methods for other generic functions must be provided by the user.<br><br>There is an example in “Defining a new stream class” on page 400. |

## **fundamental-output-stream** *Class*

Summary      A class whose inclusion causes **output-stream-p** to return t.

Package      **stream**

Superclasses    **fundamental-stream**

Subclasses     **fundamental-binary-output-stream**  
**fundamental-character-output-stream**

Description     The class **fundamental-output-stream** is a superclass to the binary and character output classes. Its inclusion causes the generic function **output-stream-p** to return t.

| Signature   | <code>stream-advance-to-column stream column =&gt; result</code>                                                                                                                                                                                                                                                           |             |
| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                        | A stream.   |
|             | <code>column</code>                                                                                                                                                                                                                                                                                                        | An integer. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                        | A boolean.  |
| Description | The generic function <code>stream-advance-to-column</code> writes enough blank spaces to <code>stream</code> to ensure that the next character is written at <code>column</code> . The generic function returns <code>t</code> if the operation is successful, or <code>nil</code> if it is not supported for this stream. |             |

This function is intended for use by `print` and `format ~t`. The default method uses `stream-line-column` and repeated calls to `stream-write-char` with a `#\Space` character, and returns `nil` if `stream-line-column` returns `nil`.

## stream-check-eof-no-hang

## *Generic Function*

**Summary**      Determines whether a stream is at end of file.

## Package stream

Signature `stream-check-eof-no-hang stream => result`

Arguments      *stream*      An input stream.

Values              *result*              nil or :eof.

**Description** The generic function `stream-check-eof-no-hang` determines if the data source of the stream is at end of file, without hanging.

*stream* should be an instance of a subclass of `buffered-stream`.

*result* is `:eof` if *stream* is at end of file and `nil` otherwise.

There is a built-in method specialized on `buffered-stream` which returns `:eof` in all cases.

See also [buffered-stream](#)

## stream-clear-input

## *Generic Function*

**Summary**      Implements `clear-input`.

| Description | <p>The generic function <code>stream-file-position</code> implements <code>file-position</code>.<br/> <code>stream-file-position</code> is called when <code>file-position</code> is called with one argument.<br/> <code>(setf stream:stream-file-position)</code> is called when <code>file-position</code> is called with two arguments.</p> <p>The return value is returned by <code>file-position</code>. For the setf function, this is a slight anomaly because setf functions normally return the new value. However in this case it should return the <code>success-p</code> value mandated by the ANSI Common Lisp standard.</p> <p>The default methods specialized on <code>stream</code> return <code>nil</code>.</p> |                                       |

**stream-fill-buffer** *Generic Function*

|         |                          |
|---------|--------------------------|
| Summary | Fills the stream buffer. |
| Package | <code>stream</code>      |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |

| Description | <p>The generic function <code>stream-fill-buffer</code> is called by the reading functions to fill an empty stream buffer from the underlying data source.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p><code>stream-fill-buffer</code> should block until some data is available or return false at end of file. If data is available, it should place it in a buffer, set the stream's input buffer, index and limit appropriately and return a true value. The existing stream buffer can be reused if desired but the index and limit must be updated. The buffer must be of type <code>simple-string</code>, whose element type matches that given when the stream was constructed.</p> <p>There is a built-in method specialized on <code>buffered-stream</code> which usually suffices. It calls <code>stream-read-buffer</code> with the whole buffer and returns false if this call returns 0. If not, the input index is set to 0 and the input limit is set to the value returned by <code>stream-read-buffer</code>.</p> |                        |

## stream-force-output

*Generic Function*

Summary      Implements **force-output**.

Package      **stream**

Signature      **stream-force-output stream => nil**

Arguments      **stream**      A stream.

Values      **nil**

Description      The generic function **stream-force-output** implements **force-output**. The default method is on **fundamental-output-stream** and does nothing.

There is an example in “Stream output” on page 402.

See also      **fundamental-output-stream**

## stream-fresh-line

*Generic Function*

Summary      Used by **fresh-line** to start a new line on a given stream.

Package      **stream**

Signature      **stream-fresh-line stream => bool**

|             |               |                                                                                                                                                                                                                                                              |

| Description |                                                                          | The generic function <b>stream-line-column</b> returns the column number where the next character will be written from <i>stream</i> , or <b>nil</b> if this is not meaningful for the stream. This function is used in the implementation of <b>print</b> and the <b>format ~t</b> directive. A method for this function must be defined for every character output stream class that is defined, although at its simplest it may be defined to always return <b>nil</b> . |

| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A generalized boolean. |
| Description | <p>The generic function <code>stream-listen</code> is called to determine if there is data immediately available on the stream <code>stream</code>, without hanging.</p> <p><code>result</code> should be true if there is input, and <code>nil</code> otherwise (including at end of file).</p> <p>This method must be implemented for subclasses of <code>buffered-stream</code> that handle input.</p> <p>There is a built-in primary method specialized on <code>buffered-stream</code> which returns <code>nil</code>. There is a built-in <code>:around</code> method specialized on <code>buffered-stream</code> which checks for input in the buffer and calls the next method if the buffer is empty. Thus a primary method specialized on a subclass of <code>buffered-stream</code> need only check the underlying data source.</p> <p>The built-in method on <code>fundamental-input-stream</code> uses <code>stream-read-char-no-hang</code> and <code>stream-unread-char</code>. Most streams should define their own method as this is usually trivial and more efficient than the method provided.</p> |                        |

| Arguments                  | <code>stream</code> | A stream.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Values                     | <code>result</code> | An integer or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                   |
| Description                |                     | The generic function <code>stream-output-width</code> is used by the pretty printer to determine the output width when <code>*print-right-margin*</code> is <code>nil</code> . It returns <code>result</code> , the integer width of <code>stream</code> in units of ems, or <code>nil</code> if the width is not known. The default method provided by <code>fundamental-stream</code> returns <code>nil</code> . |

| Summary                 |                     | A generic function used by <code>peek-char</code> that returns a character on a given stream without removing it from the stream buffer. |
| Package                 | <code>stream</code> |                                                                                                                                          |
| Signature               |                     | <code>stream-peek-char stream =&gt; result</code>                                                                                        |
| Arguments               | <code>stream</code> | A stream.                                                                                                                                |
| Values                  | <code>result</code> | A character or <code>:EOF</code> symbol.                                                                                                 |

|             |                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The generic function <code>stream-peek-char</code> is used to implement <code>peek-char</code> , and corresponds to a peek-type of <code>nil</code> . The default method reads a character from the stream without removing it from the stream buffer, by using <code>stream-read-char</code> and <code>stream-unread-char</code> . |

## stream-read-byte *Generic Function*

**Summary** A generic function used by `read-byte` to read an integer or `:eof` symbol from a binary stream.

## Package stream

Signature **stream-read-byte** *stream* => *result*

**Arguments**      *stream*      An input stream.

Values            *result*            An integer or :eof.

**Description** The generic function `stream-read-byte` is used by `read-byte`, and returns either an integer read from the binary stream specified by `stream`, or the keyword :`eof`.

A method must be implemented for all binary subclasses of `buffered-stream` that handle input. A typical implementation will call `stream-read-char` and convert the character to an integer using `char-code`.

A method should be defined for a subclass of `fundamental-binary-input-stream`.

## **stream-read-char-no-hang**

## *Generic Function*

|             |                                                                                                                               |                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| Summary     | Returns either a character from the stream, an :eof if the end-of-file is reached, or nil if no input is currently available. |                                             |
| Package     | <b>stream</b>                                                                                                                 |                                             |
| Signature   | <b>stream-read-char-no-hang <i>stream</i> =&gt; <i>result</i></b>                                                             |                                             |
| Arguments   | <i>stream</i>                                                                                                                 | An input stream.                            |
| Values      | <i>result</i>                                                                                                                 | Either a character, an :EOF symbol, or nil. |
| Description | The generic function <b>stream-read-char-no-hang</b> implements <b>read-char-no-hang</b> . It returns either a character read |                                             |

from the stream, or `:eof` if end-of-file is reached, or `nil` if no input is available. The default method provided by `fundamental-character-input-stream` simply calls `stream-read-char` which is sufficient for file streams, but interactive streams should define their own method.

## **stream-read-sequence**

## *Generic Function*

**Summary**     Reads a number of items from a stream into a sequence.

**Package**     **stream**

**Signature**     **stream-read-sequence stream sequence start end => index**

**Arguments**     **stream**     A stream.

**sequence**     A sequence.

**start**     An integer.

**end**     An integer.

**Values**     **index**     An integer.

**Description**     The generic function **stream-read-sequence** reads from *stream* into *sequence*. Elements from the *start* of *sequence* are replaced by elements from *stream* until *end* in *sequence* or the end-of-file in *stream* is reached. The index of the first element in *sequence* that is not replaced is returned.

A default method is provided by **fundamental-character-input-stream** which makes repeated calls to **stream-read-char** and uses **(setf elt)** to insert characters into *sequence*. A default method is provided by **fundamental-binary-input-stream** that makes repeated calls to **stream-read-byte** and also uses **(setf elt)** to insert bytes into *sequence*. Note that this may lead to error if the sequence is of inappropriate type.

**stream-start-line-p** *Generic Function*

|             |                                                                                                                                                   |            |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Summary     | A generic function that returns <b>t</b> if the stream is positioned at the beginning of a line.                                                  |            |
| Package     | <b>stream</b>                                                                                                                                     |            |
| Signature   | <b>stream-start-line-p</b> <i>stream</i> => <i>result</i>                                                                                         |            |
| Arguments   | <i>stream</i>                                                                                                                                     | A stream.  |
| Values      | <i>result</i>                                                                                                                                     | A boolean. |
| Description | The generic function <b>stream-start-line-p</b> returns <b>t</b> if <i>stream</i> is positioned at the beginning of a line, and <b>nil</b> other- |            |

wise. It is permissible to define a method that always returns `nil`.

Note that although a value of 0 from `stream-line-column` also indicates the beginning of a line, there are cases where `stream-start-line-p` can be meaningfully implemented and `stream-line-column` cannot. For example, for a window using variable-width characters the column number is not very meaningful, whereas the beginning of a line has a clear meaning.

The default method for `stream-start-line-p` on class `fundamental-character-output-stream` uses `stream-line-column`. Therefore, if this is defined to return `nil`, a method should be provided for either `stream-start-line-p` or `stream-fresh-line`.

## **stream-write-buffer** *Generic Function*

|           |                                                    |                                                       |
|-----------|----------------------------------------------------|-------------------------------------------------------|
| Summary   | Writes a part of stream's buffer.                  |                                                       |
| Package   | <b>stream</b>                                      |                                                       |
| Signature | <b>stream-write-buffer stream buffer start end</b> |                                                       |
| Arguments | <i>stream</i>                                      | An output stream.                                     |
|           | <i>buffer</i>                                      | A stream buffer.                                      |
|           | <i>start, end</i>                                  | Bounding indexes for a subsequence of <i>buffer</i> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The generic function <code>stream-write-buffer</code> is called by <code>stream-flush-buffer</code> to write the region of the buffer bounded by <code>start</code> and <code>end</code> to the stream's underlying data sink.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p>This method must be implemented for subclasses of <code>buffered-stream</code> that handle output.</p> |
| See also    | <p><code>buffered-stream</code></p> <p><code>stream-flush-buffer</code></p>                                                                                                                                                                                                                                                                                                                                                                     |

## **stream-write-byte** *Generic Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Summary     | A generic function used by <code>write-byte</code> to write an integer to a binary stream.                                                                                                                                                                                                                                                                                                                                                                 |             |
| Package     | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |
| Signature   | <code>stream-write-byte stream integer =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                 |             |
| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        | A stream.   |
|             | <code>integer</code>                                                                                                                                                                                                                                                                                                                                                                                                                                       | An integer. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        | An integer. |
| Description | <p>The generic function <code>stream-write-byte</code> is used by <code>write-byte</code>, and writes the integer <code>integer</code> to the binary stream specified by <code>stream</code>.</p> <p>A method must be implemented for all binary subclasses of <code>buffered-stream</code> that handle output. A typical implementation will convert the integer to a character using <code>code-char</code> and call <code>stream-write-char</code>.</p> |             |

A method should be defined for all subclasses of **fundamental-binary-output-stream**.

## **stream-write-char** *Generic Function*

Summary      Writes a character to a specified stream.

Package      **stream**

Signature      **stream-write-char stream character => character**

Arguments      **stream**      A stream.  
**character**      A character.

Values      **character**      A character.

Description      The generic function **stream-write-char** writes *character* to *stream*. Every subclass of **fundamental-character-output-stream** must have a method defined for this function.  
There is an example in “Stream output” on page 402.

See also      **fundamental-character-output-stream**

## **stream-write-sequence** *Generic Function*

Summary      Writes a subsequence of a sequence to a stream.

Package      **stream**

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <code>with-stream-input-buffer</code> allows access to the state of the input buffer for the given buffered stream.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p>Within the code <code>body</code>, the variables <code>buffer</code>, <code>index</code> and <code>limit</code> are bound to the buffer of <code>stream</code>, its current index and the limit of the buffer. Setting <code>buffer</code>, <code>index</code> or <code>limit</code> will change the values in the stream <code>stream</code> but note that other changes to these values (for example, by calling other stream functions) will not affect the values bound within the macro. See the example for a typical use which shows how this restriction can be handled.</p> <p>The buffer is always of type <code>simple-string</code>. The <code>stream-element-type</code> of <code>stream</code> depends on how it was constructed.</p> <p>The index is the position of the next element to be read from the buffer and the limit is the position of the element after the end of the buffer. Therefore there is no data in the buffer when <code>index</code> is greater than or equal to <code>length</code>.</p> |
| Example     | This example function returns a string with exactly four characters read from a buffered stream. If <code>end-of-file</code> is reached before four characters have been read, it returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## with-stream-output-buffer

*Macro*

Summary      Allows access to the output buffer.

Package      **stream**

Signature      **with-stream-output-buffer** (*buffer index limit*) **stream &body body** => *result*

Arguments      *buffer, index, limit*

### Variables

*stream*      An output stream

*body*      Code

Values      *result*      The value returned by body.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Arguments   | <i>object</i>                                                                 | Any object.                                                                                                                                     |
| Values      | <i>result</i>                                                                 | A boolean.                                                                                                                                      |
| Description |                                                                               | The function <code>allocated-in-its-own-segment-p</code> returns true if <i>object</i> is allocated in its own own segment and false otherwise. |

|          |                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | An object is allocated in its own segment if it is "very large". Currently that means larger than 64 MB for the ordinary 64-bit GC, or larger than 1 MB for the Mobile GC.                                                        |
|          | <code>allocated-in-its-own-segment-p</code> is intended to help to decide whether to call the functions that are useful only for such objects ( <code>make-object-permanent</code> and <code>release-object-and-nullify</code> ). |
| See also | <code>make-object-permanent</code><br><code>release-object-and-nullify</code><br>"Mobile GC technical details" on page 154                                                                                                        |

|             |                                                                                                                                                             | <i>Function</i>                                                                                                                                                                                                                                                                                      |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Allows control over which generation objects are allocated in, in 64-bit LispWorks.                                                                         |                                                                                                                                                                                                                                                                                                      |

| Description | The function <code>apply-with-allocation-in-gen-num</code> applies the function <code>func</code> to <code>args</code> such that objects of allocation type |                                                                                                                                                                                                                                                                                                      |

*what* are allocated in generation *gen-num*, in 64-bit LispWorks.

See also the keyword :**allocation** to **make-array**, which catches the most common cases.

It is probably quite rare that it is useful to use this function, unless the function allocates a lot, and you are certain that every object that is allocated of the allocation type is long-lived, which is normally difficult to tell.

Notes

1. Allocation of interned symbols is controlled separately by **\*symbol-alloc-gen-num\***.
2. In 32-bit LispWorks the argument *what* is ignored and the effect is like that of the macro **allocation-in-gen-num**.
3. In the Mobile GC, *gen-num* must be 0, 1 or 2.

## approaching-memory-limit

*Condition*

Summary

The class of conditions signalled when 32-bit LispWorks approaches its memory limit.

Package

**system**

Superclasses

**storage-condition**

Subclasses

None.

Description

The condition class **approaching-memory-limit** is used for signalling an error when 32-bit LispWorks approaches its memory limit.

|          |                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------|
| Notes    | <code>approaching-memory-limit</code> is not relevant to 64-bit Lisp-Works.                      |

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Summary     | Like <b>push</b> , but does the operation atomically.                                                                                                                                                                                       |                                                                            |
| Package     | <b>system</b>                                                                                                                                                                                                                               |                                                                            |
| Signature   | <b>atomic-push</b> <i>new-value place</i> => <i>new-place-value</i>                                                                                                                                                                         |                                                                            |
| Arguments   | <i>new-value</i>                                                                                                                                                                                                                            | An object.                                                                 |
|             | <i>place</i>                                                                                                                                                                                                                                | One of the specific set of places defined for low level atomic operations. |
| Values      | <i>new-place-value</i>                                                                                                                                                                                                                      | A list (the new value of place).                                           |
| Description | The macro <b>atomic-push</b> is the same as <b>c1:push</b> , but is guaranteed atomic for a suitable place.<br><br><i>place</i> must be one of the places described in “Low level atomic operations” on page 299, or expand to one of them. |                                                                            |
| Notes       | In many cases the natural inverse of <b>push</b> is <b>delete</b> , but there is no way to do <b>delete</b> atomically, except by using a separate <b>lock</b> , which must also be held while doing the <b>push</b> .                      |                                                                            |
| See also    | <b>atomic-pop</b><br><b>low-level-atomic-place-p</b>                                                                                                                                                                                        |                                                                            |

## \*binary-file-type\* *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The default file type of binary files.                                                                                                                                                                                                                                                                                                                                                                         |
| Package       | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                            |
| Initial value | The initial value of <code>*binary-file-type*</code> depends on the host CPU and the LispWorks implementation. See “Naming conventions for FASL files” on page 648.                                                                                                                                                                                                                                            |
| Description   | <p>The variable <code>*binary-file-type*</code> is the file type that <code>load</code> and <code>require</code> recognize as a binary (FASL) file (in addition to any additional file types in <code>*binary-file-types*</code>).</p> <p>Normally you should not set <code>*binary-file-type*</code>. If you need to load files with another type, push that type on to <code>*binary-file-types*</code>.</p> |
| See also      | <code>*binary-file-types*</code><br><code>load-data-file</code>                                                                                                                                                                                                                                                                                                                                                |

## \*binary-file-types\* *Variable*

|               |                                                       |
|---------------|-------------------------------------------------------|
| Summary       | A list of file types that are loaded as binary files. |
| Package       | <code>system</code>                                   |
| Initial value | <code>nil</code>                                      |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The variable <b>*binary-file-types*</b> contains a list of strings naming file types which <b>load</b> and <b>require</b> recognize as binary (FASL) files. FASL files are the output of <b>compile-file</b>, <b>dump-forms-to-file</b> or <b>with-output-to-fasl-file</b>.</p> <p>You need to add a type to this list if you want load such files but they have an extension which is different from the default (the value of <b>*binary-file-type*</b>).</p> |
| See also    | <b>*binary-file-type*</b>                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                    |                                                                                                                                                                                                                                                               | <i>Function</i> |

| Signature          | <b>call-system</b> <i>command</i> & <b>key</b> <i>current-directory</i> <i>wait</i> <i>shell-type</i> => <i>status</i> , <i>signal-number</i>                                                                                                                 |                 |
| Arguments          | <p><i>command</i> A string, a list of strings, a simple-vector of strings, or <b>nil</b>.</p> <p><i>current-directory</i> A string. Implemented only on Microsoft Windows.</p> <p><i>wait</i> A boolean.</p> <p><i>shell-type</i> A string or <b>nil</b>.</p> |                 |
| Values             | <p><i>status</i> The exit status of the invoked shell or process.</p> <p><i>signal-number</i> On Unix-like systems, if the process was terminated by a signal this is the signal number, otherwise <b>nil</b>. Always <b>nil</b> on Microsoft Windows.</p>    |                 |
| Description        | <b>call-system</b> allows executables and DOS or Unix shell commands to be called from Lisp code as a separate OS process.                                                                                                                                    |                 |

The output goes to standard output, as the operating system sees it. (This normally means `*terminal-io*` in LispWorks.)

If *command* is a string then it is passed to the shell as the command to run, using the `-c` option, without any other arguments. The type of shell to run is determined by *shell-type* as described below. Note that for typical Unix shells, the string *command* may contain multiple commands separated by `:` (semicolon).

If *command* is a list then it becomes the argv of a command to run directly, without invoking a shell. The first element is the command to run directly and the other elements are passed as arguments on the command line (that is, element 0 has its name in `argv[0]` in C, and so on).

If *command* is a simple vector of strings, the element at index 0 is the command to run directly, without invoking a shell. The other elements are the complete set of arguments seen by the command (that is, element 1 becomes `argv[0]` in C, and so on).

If *command* is `nil`, then the shell is run.

On Microsoft Windows, if *command* is a string, LispWorks hides the first window of the execution of the command, because that is the console that `cmd.exe` starts in a DOS window. If the command itself is a console application, you may want to see the console. In this case run the command as a direct command. To do this, pass a list or a vector as described above. Conversely, if you run a console application and do not want to see the console, pass the command as a string.

On Microsoft Windows *current-directory* is the `lpCurrentDirectory` argument passed to `CreateProcess`. If this is not supplied, the `pathname-location` of the `current-pathname` is passed.

If *wait* is true, `call-system` does not return until the process has exited. The default for *wait* is `t`.

On non-Windows platforms, if *shell-type* is a string it specifies the shell. If *shell-type* is `nil` (the default) then the Bourne shell, `/bin/sh`, is used. The C shell may be obtained by passing `"/bin/csh"`.

On supported versions of Microsoft Windows if *shell-type* is `nil` then `cmd.exe` is used.

`call-system` returns the exit status of the process it created. Additionally on Unix-like systems if the process was terminated by a signal then `call-system` returns the number of that signal. For a discussion of these return values see “Interpreting the exit status” on page 462.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes               | If you need to be able to check whether the child process is alive and maybe to kill it, use <code>open-pipe</code> with <code>:save-exit-status t</code> (and maybe <code>:direction :none</code> ) instead of <code>call-system</code> , and then use <code>pipe-exit-status</code> and maybe <code>pipe-kill-process</code> .                                                                                                                                                                                                                                                        |
| Compatibility notes | <ol style="list-style-type: none"> <li>1. The argument <code>:shell-type</code> is not implemented in LispWorks for Windows 4.4 and earlier, and <code>cmd.exe</code> is not used implicitly.</li> <li>2. On Microsoft Windows, LispWorks 5.0 and later use <i>shell-type</i> <code>cmd.exe</code> by default when <i>command</i> is a string. In LispWorks 5.x the user may see a DOS command window in this case, but LispWorks 6.0 and later explicitly hide the DOS window. To call your command directly <i>command</i> should be a list, as in the last example below.</li> </ol> |
| Example             | <p>On Unix:</p> <pre>(call-system (format nil "adb ~a &lt; ~a &gt; ~a"                       (namestring a)                       (namestring b)                       (namestring c)))</pre> <p>On Microsoft Windows:</p>                                                                                                                                                                                                                                                                                                                                                              |

```
(sys:call-system "sleep 3" :wait t)

(sys:call-system '("notepad" "myfile.txt"))
```

## call-system-showing-output

## Function

Package `system`

Signature `call-system-showing-output command &key current-directory  
prefix show-cmd output-stream wait shell-type kill-process-on-abort  
=> status`

Arguments `command` A string, a list of strings, a simple-vector of strings, or `nil`.

`current-directory` A string. Supported only on Microsoft Windows.

`prefix` A string.

`show-cmd` A boolean.

`output-stream` An output stream or `nil`, `t` or `:tty`.

`wait` A boolean.

`shell-type` A string. Supported only on non-Windows platforms.

`kill-process-on-abort`

A generalized boolean.

Values `status` The exit status of the invoked shell or process.

| Description | <code>call-system-showing-output</code> is an extension to <code>call-system</code> which allows output to be redirected. On non-Windows platforms this means it can be redirected to places other than the shell process from which the LispWorks image was invoked. <code>call-system-showing-output</code> therefore allows the user to, for example, invoke a shell command and redirect the output to the current Listener window.<br><br>The argument <i>command</i> is interpreted as by <code>call-system</code> . On Microsoft Windows there is one difference: when <i>command</i> is a list or vector and the executable (that is, the first element of the sequence <i>command</i> ) in <code>call-system-showing-output</code> is not a GUI application, LispWorks hides the first window, which is the console that the executable will normally open. Note that for a non-direct command (that is, a string) LispWorks always hides the first window (which is the console) in both <code>call-system</code> and <code>call-system-showing-output</code> .<br><br><i>prefix</i> is a prefix to be printed at the start of any output line. The default value is " ; ".<br><br><i>show-cmd</i> specifies whether or not the <i>cmd</i> invoked will be printed as well as the output for that command. If <i>t</i> then <i>cmd</i> will be printed. The default value for <i>show-cmd</i> is <i>t</i> .<br><br><i>output-stream</i> specifies where the output will be sent to. If <i>output-stream</i> is an output stream, the output is written to it. If <i>output-stream</i> is <i>t</i> , the output is written to <code>*standard-output*</code> . If <i>output-stream</i> is <i>nil</i> , the output is collected as a string, and returned as a second value from <code>call-system-showing-output</code> . If <i>output-stream</i> is <code>:tty</code> , <code>call-system-showing-output</code> behaves like <code>call-system</code> . The default value is <code>*standard-output*</code> .<br><br>If <i>wait</i> is true, <code>call-system-showing-output</code> does not return until the process has exited. If <i>nil</i> , <code>call-system-showing-output</code> returns immediately and no output is shown. The default for <i>wait</i> is <i>t</i> . |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*shell-type* is a string naming a UNIX shell. The default is "/bin/sh".

If *kill-process-on-abort* is true, then when **call-system-showing-output** is aborted the process is killed. The default value of *kill-process-on-abort* is nil.

**call-system-showing-output** returns the exit status of the shell invoked to execute the command on non-Windows platforms, or the process created on Microsoft Windows.

## Examples

### On Linux:

```
CL-USER 1 > (sys:call-system-showing-output "pwd"
  :prefix "***")
***pwd
***/amd/xanfs1-cam/u/ldisk/sp/lispsrc/v42/builds
0
```

```
CL-USER 2 > (sys:call-system-showing-output "pwd"
  :prefix "&&" :show-cmd nil)
&&/amd/xanfs1-cam/u/ldisk/sp/lispsrc/v42/builds
0
```

### On Microsoft Windows:

```
CL-USER 223 > (sys:call-system-showing-output
  "cmd /c type hello.txt"
  :prefix "***")
***cmd /c type hello.txt
***Hi there
0
```

```
CL-USER 224 > (sys:call-system-showing-output
  "cmd /c type hello.txt"
  :prefix "&&"
  :show-cmd nil)
&&Hi there
0
```

| <i>place</i>    | A setf place containing an association list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |            |              |                      |             |                        |                 |                        |            |                        |              |                                              |              |            |
| <i>value</i>    | An object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |            |              |                      |             |                        |                 |                        |            |                        |              |                                              |              |            |
| Values          | <i>result</i> An object (from <i>alist</i> ) or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |            |              |                      |             |                        |                 |                        |            |                        |              |                                              |              |            |
| Description     | <p>The accessor <code>cdr-assoc</code> provides a generalized reference for elements in an association list. The arguments are all as specified for the Common Lisp function <code>assoc</code>. <code>cdr-assoc</code> and its setf expander read and write the <code>cdr</code> of an element in a manner consistent with the Common Lisp notion of places.</p> <p><code>cdr-assoc</code> returns the <code>cdr</code> of the first cons in the alist <i>alist</i> that matches <i>item</i> (tested using <i>test</i>, <i>test-not</i> and <i>key</i> as for <code>assoc</code>), or <code>nil</code> if no element of <i>alist</i> matches.</p> <p>Using <code>cdr-assoc</code> with <code>setf</code> modifies the first cons in the value of <i>place</i> that matches <i>item</i>, setting its <code>cdr</code> to <i>value</i>. If no element matches, then it pushes the value of <code>(cons item value)</code> onto the value of <i>place</i> and sets <i>place</i> to this new alist. This is similar to how <code>cl:getf</code> is defined.</p> |             |            |              |                      |             |                        |                 |                        |            |                        |              |                                              |              |            |

When *place* is a globally accessible place that may be read by another thread without synchronization (by a lock or other synchronization mechanism), you need to wrap *alist* by `globally-accessible`. See “Making an object’s contents accessible to other threads” on page 268 for a discussion.

#### Example

```
CL-USER 1 > (defvar *my-alist*
  (list (cons :foo 1)
        (cons :bar 2)))
*MY-ALIST*

CL-USER 2 > (setf (sys:cdr-assoc :bar
  *my-alist*) 3)
3

CL-USER 3 > *my-alist*
((:FOO . 1) (:BAR . 3))
```

### \*check-network-server\*

### Variable

#### Summary

Indicates the presence of a network license.

**Note:** LispWorks for UNIX only.

#### Package

`system`

#### Description

This should always be set to `t` for a site (that is, network) license — the licensing mechanism does not work in any other circumstances. Do not set the variable otherwise, as it overrides any useful diagnostics which may accompany keyfile errors. Not applicable to LispWorks for Linux, Windows, x86/x64 Solaris, FreeBSD, AIX or Macintosh.

### coerce-to-gesture-spec

### Function

#### Summary

Returns a Gesture Spec object.

#### Package

`system`

| Arguments   | <i>object</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A character, keyword, Gesture Spec or string. |
|             | <i>errorp</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A boolean.                                    |
| Values      | <i>gspec</i> A Gesture Spec object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                               |
| Description | <p>The function <code>coerce-to-gesture-spec</code> returns a Gesture Spec object <i>gspec</i> which can be used to represent the key-stroke indicated by <i>object</i>.</p> <p>If <i>object</i> is a Lisp character, then <i>gspec</i>'s data is its <code>c1:char-code</code> and <i>gspec</i>'s modifiers are 0.</p> <p>If <i>object</i> is a keyword, then it must be one of the known Gesture Spec keywords and becomes <i>gspec</i>'s data. <i>gspec</i>'s modifiers is 0.</p> <p>If <i>object</i> is a string, then <code>coerce-to-gesture-spec</code> expects it to be a sequence of modifier key names separated by the - character, followed by a single character or a character name as returned by <code>name-char</code> or the name of one of the known Gesture Spec keywords. Then <i>gspec</i> contains the corresponding Gesture Spec keyword or <code>char-code</code> in its <i>data</i>, and the modifier keys are represented in its <i>modifiers</i>.</p> <p>If <i>object</i> is a Gesture Spec object, it is simply returned.</p> <p><code>coerce-to-gesture-spec</code> does not create wild gesture specs.</p> |                                               |

|          |                                                                                                                                                                                                                                                                                                  |

| Description | <p>The macro <code>compare-and-swap</code> compares the value in <i>place</i> with <i>compare</i>, and if they are the same (by <code>eq</code>), stores the <i>new-value</i> in <i>place</i>.</p> <p><code>compare-and-swap</code> returns non-nil if the store occurred, or <code>nil</code> if the store did not occur.</p> <p><i>place</i> must be one of the places described in “Low level atomic operations” on page 299, or expand to one of them.</p> <p>The operation is guaranteed to be atomic.</p> |

| Description                                | <p>The function <code>copy-preferences-from-older-version</code> copies uses preferences from one part of the registry to another.</p> <p><i>old-path</i> and <i>new-path</i> are the paths of preferences for the old and the new version, corresponding to the paths that were passed to <code>(setf product-registry-path)</code>.</p> <p><i>flag-name</i> is a name of the flag to use to record in the registry that the copy is already done. <i>flag-name</i> must be a valid regis-</p> |                 |                    |                 |                    |                  |           |

try value name on Microsoft Windows, and a valid filename on all other platforms. The default value of *flag-name* is the string "copied-old-preferences".

`copy-preferences-from-older-version` performs several checks:

1. It checks whether it already copied to *new-path* in the current session, and if so does nothing.
  2. It checks whether the *flag-name* entry exists, and if so it does nothing.
  3. It checks whether another call to `copy-preferences-from-older-version` is already executing (in another thread), and if so it just waits for the other call to finish.

Then if all the checks above indicate that copying is still needed, `copy-preferences-from-older-version` copies the values from the tree below `old-path` to a tree below `new-path`. It traverses the entire tree below `old-path`, and checks each key to see if it has any values.

For a key that has values, it checks whether the key exists under *new-path*, and if the key exists it does not copy any of the values for this key, though it still traverses and maybe copies its subkeys. If the key does not exist under *new-path*, it creates the key and copies the values.

Because it makes checks before doing any work, `copy-preferences-from-older-version` is an inexpensive call that can be used freely.

| Signature   | <code>count-gen-num-allocation gen-num &amp;optional include-lower-generations</code>                                                                                                                                                                                                                              |
| Arguments   | <p><i>gen-num</i> An integer between 0 and 7, inclusive.</p> <p><i>include-lower-generations</i> A generalized boolean.</p>                                                                                                                                                                                        |
| Values      | <i>allocation</i> An integer.                                                                                                                                                                                                                                                                                      |
| Description | The function <code>count-gen-num-allocation</code> returns the amount of allocated data in generation <i>gen-num</i> . If <i>include-lower-generations</i> is non-nil, the returned value <i>allocation</i> also includes the data in the younger generations.                                                     |
| Notes       | <p><code>count-gen-num-allocation</code> is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations, where you can use <code>room-values</code> instead.</p> <p>On the Mobile GC, the <i>gen-num</i> argument can be 0, 1, 2 or 3 (3 means permanent).</p> |

|                                                   |                                                                                                                           |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>*debug-initialization-errors-in-snap-shot*</b> | <i>Variable</i>                                                                                                           |
| Summary                                           | Controls use of the snapshot debugger.                                                                                    |
| Package                                           | <code>system</code>                                                                                                       |
| Initial value                                     | <code>t</code>                                                                                                            |
| Description                                       | The variable <code>*debug-initialization-errors-in-snap-shot*</code> controls whether, in an image which is configured to |

start the LispWorks IDE automatically, an error during initialization is handled and displayed in a snapshot debugger after the IDE starts.

If the value of `*debug-initialization-errors-in-snapshot*` is `nil` LispWorks behaves like LispWorks 5.0 and previous versions. That is, it attempts to enter the command line debugger.

| Description                              | This variable determines the maximum size of the stack cache.<br><br>Process stacks are cached and reused. When a process dies, its stack is put in the stack cache for future reuse if there are currently less than <b>*default-stack-group-list-length*</b> stacks in the cache. Therefore if your application repeatedly creates and discards more than 10 processes you should consider increasing the value of this variable.<br><br>Note that stacks are allocated in generation 2, hence a program with a high turnover of processes may need to call <code>(gc-generation t)</code> periodically unless all the stacks of dead processes are reused. |                 |
|                                          | The default stack size is 64 KB on all 32-bit LispWorks x86 platforms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |

| Description |                    | <p>The macro <code>define-atomic-modify-macro</code> has the same syntax as <code>cl:define-modify-macro</code>, and performs a similar operation.</p> <p>The resulting macro <i>name</i> can be used only on one of the specific set of places defined for low level atomic operations as listed in “Low level atomic operations” on page 299. The macro <i>name</i> reads the value of the <i>place</i>, calls the function <i>function</i>, and then writes the result of the function call if the value in <i>place</i> has not changed since it was first read. If that value did change, the operation is repeated until it succeeds.</p> <p>Note that this means:</p> <ol style="list-style-type: none"> <li>1. The function <i>function</i> may be called more than once for each invocation of the defined macro. Therefore <i>function</i> should not have any side effects.</li> <li>2. <i>function</i> must be thread-safe, because it may run concurrently in several threads if the defined macro <i>name</i> is used from several threads simultaneously.</li> <li>3. It is possible in principle for the value to change more than once between reading the <i>place</i> and writing the new value. This may end up resetting the value in <i>place</i> to its original value, and hence the operation will succeed. This is equivalent to the code being invoked after the last change, unless <i>function</i> itself looks at <i>place</i>, which may cause inconsistent results.</li> </ol> |

| Description | <p>The macro <code>define-top-loop-command</code> defines a top level loop command called <i>name</i> which takes the parameters specified by <i>lambda-list</i>. If <code>&amp;whole</code> is used in <i>lambda-list</i> then the variable will be bound to a list containing the whole command line, including the command name, but the command name is not included in <i>lambda-list</i> otherwise.</p> <p>If any aliases are specified in <i>option</i>, these keywords will also invoke the command.</p> <p>When the command is used, each form is evaluated in sequence with the variables from <i>lambda-list</i> bound to the subsequent forms on the command line.</p> <p>If <i>result-type</i> is <code>values</code> (the default), then the values of the last form will be returned to the top level loop.</p> |                                                                                                                                                                                                  |

If *result-type* is `eval`, then the value of the last form should be a form and is evaluated by the top level loop as if it had been entered at the prompt.

If *result-type* is `nil`, then the last form should return two values. If the second value is `nil` then the first value is treated as a list of values to returned to the top level loop. If the second value is non-nil then the first value should be a form and is evaluated by the top level loop as if it had been entered at the prompt.

Notes      For details of pre-defined top level loop commands, enter `:?` at the Listener prompt.

Example    Given this definition:

```
(define-top-loop-command (:lave
                           (:result-type eval)) (form)
                           (reverse form))
```

then the command line

```
:lave (1 2 list)
```

will evaluate the form `(list 2 1)`.

Here are definitions for two commands both of which will run `apropos`:

```
(define-top-loop-command (:apropos-eval
                           (:result-type eval))
                           (&rest args)
                           ` (apropos ,@args))

(define-top-loop-command :apropos-noeval (&rest args)
                           (apply 'apropos args))
```

The first one will evaluate the arguments before calling `apropos` whereas the second one will just pass the forms, so

```
:apropos-noeval foo
```

will find all the symbols containing the string `foo`, whereas

```
(setq foo "bar")
```

```
:apropos-eval foo
```

will find all the symbols containing the string `bar`.

| Values      | <code>new-ef-spec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A new external format spec created by merging <i>ef-spec</i> with the encoding that was found. |
| Description | When the encoding in <i>ef-spec</i> has foreign type ( <code>unsigned-byte 8</code> ), search <i>buffer</i> up to <i>length</i> for the first occurrence of the byte ( <code>10</code> ). If found, and it is preceded in <i>buffer</i> by ( <code>13</code> ), merge <i>ef-spec</i> with<br><code>(:default :eol-style :crlf)</code><br>If found and is not preceded by ( <code>13</code> ), merge <i>ef-spec</i> with<br><code>(:default :eol-style :lf)</code><br>Thus a complete external format spec is constructed. Otherwise, return <i>ef-spec</i> . |                                                                                                |

When the encoding in *ef-spec* has foreign type (`unsigned-byte 16`), search *buffer* up to *length* for the first occurrence of the byte sequence (13 0 10). If found, merge *ef-spec* with

```
(:default :eol-style :crlf)
```

If (13 0 10) is not found, search *buffer* up to *length* for (10 0) or (0 10). If found, merge *ef-spec* with

```
(:default :eol-style :lf)
```

Thus a complete external format spec is constructed. Otherwise, return *ef-spec*.

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Assume the encoding is one of <code>:jis</code> , <code>:sjis</code> , <code>:euc</code> , <code>:unicode</code> and <code>:ascii</code> , and try to determine which of these it is, by looking for distinctive byte sequences in <i>buffer</i> up to <i>length</i> . If found, merge <i>ef-spec</i> with that encoding. |

|             | <i>buffer</i>                                                                                                                                                                                                                                       | A buffer whose contents are examined.                                                          |  |
|             | <i>length</i>                                                                                                                                                                                                                                       | Length (an integer) up to which <i>buffer</i> should be examined.                              |  |
| Values      | <i>new-ef-spec</i>                                                                                                                                                                                                                                  | A new external format spec created by merging <i>ef-spec</i> with the encoding that was found. |  |
| Description | These functions are called as part of <code>open</code> 's encoding detection routine, and try to detect the encoding if it is not already supplied in the <i>external-format</i> argument.                                                         |                                                                                                |  |

`detect-unicode-bom` tries to detect UTF-16 encoding.

`detect-utf32-bom` tries to detect UTF-32 encoding.

`detect-utf8-bom` tries to detect UTF-8 encoding.

These functions work by checking whether the file starts with the Unicode character `#xFEFF` (BOM) encoded in the relevant encoding, and if it does assumes the file is encoded in this encoding. `detect-unicode-bom` and `detect-utf32-bom` also deduce the direction (little-endian or big-endian).

Note that files starting with `0xFF 0xFE 0x00 0x00` can match both UTF-16 and UTF-32 little-endian. By default `detect-utf32-bom` is applied first, because it precedes `detect-unicode-bom` in `*file-encoding-detection-algorithm*`. You can change this behavior by altering the order of functions in `*file-encoding-detection-algorithm*`.

## **\*directory-link-transparency\*** *Variable*

**Summary** Controls whether `directory` returns truenames on Unix-like systems.

**Package** `system`

**Initial value** `t` on non-Windows platforms, `nil` on Microsoft Windows.

**Description** In line with the ANSI Common Lisp standard, `directory` returns truenames by default.

Setting `*directory-link-transparency*` to `nil` allows you to get the old behavior of `directory`, whereby soft links are not resolved in the pathnames returned.

**\*directory-link-transparency\*** is the default value of the *link-transparency* argument to **directory**.

## ensure-loads-after-loads *Function*

Summary      Ensures all following loads in the program are executed after all prior loads.

Package      **system**

Signature      **ensure-loads-after-loads => nil**

Description      **ensure-loads-after-loads** is a synchronization function which ensures order of memory between operations in different threads.

See “Ensuring order of memory between operations in different threads” on page 301 for a full description and example.

Notes      You should have a good understanding of multiprocessing issues at the CPU level to write code that actually needs this.
