| Description             | <p>The external format <b>:utf-16</b> and variants implement translations according to the UTF-16 standard of Unicode. The variants differ only in their treatment of byte order. The parameter <i>use-replacement</i> is a boolean which defaults to <b>nil</b>. It controls what happens when reading encounters an illegal combination. Illegal combinations are either a leading surrogate (#xd800 to #xdbff) not followed by a trailing surrogate (#xdc00 to #xffff), or a trailing surrogate not following a leading surrogate. By default, the input code signals an error of type <b>external-format-error</b>. If <i>use-replacement</i> is non-nil, the input code replaces the error byte or pair of bytes by the replacement character (#xffffd).</p> <p><b>:utf-16-native</b> and <b>:utf-16-reversed</b> implement UTF-16 in the native or the reverse of the byte order of the computer that they are executing on.</p> <p><b>:utf-16be</b> and <b>:utf-16le</b> implement the UTF-16BE and UTF-16LE standard format, that is UTF-16 big-endian and</p> |

UTF-16 little-endian. The system maps these to either of `:utf-16-native` or `:utf-16-reversed`.

`:utf-16` implements the UTF-16 standard. The byte order defaults to big-endian byte order.

When opening a file with `:external-format :utf-16` (without passing *little-endian*), the system checks for the existence of the BOM (Byte Order Mark) in the beginning of the file, and if there is a BOM uses it to determine the right byte order. Otherwise, it uses big-endian (`:utf-16be`). There are no checks for a BOM in other situations.

|                     |                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility notes | These formats were new in LispWorks 7.0.<br>In LispWorks 6.1 and earlier versions the <code>:unicode</code> external format is the format to read 16-bit characters. |

`:utf-32`

`:utf-32le`

`:utf-32be`

`:utf-32-native`

`:utf-32-reversed`

*External Formats*

Summary      Implement UTF-32 format, which means reading and writing 32-bit chunks as characters.

Signature      `:utf-32 &key use-replacement little-endian`  
`:utf-32le &key use-replacement`  
`:utf-32be &key use-replacement`  
`:utf-32-native &key use-replacement`  
`:utf-32-reversed &key use-replacement`

|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description         | <p>The external format <code>:utf-32</code> and its variants implement UTF-32 format, which means reading and writing 32-bit chunks as characters.</p> <p><code>:utf-32-native</code> and <code>:utf-32-reversed</code> are the actual implementation formats. They implement UTF-32 with the native byte order (<code>:utf-32-native</code>) or the reversed byte order (<code>:utf-32-reversed</code>).</p> <p><code>:utf-32le</code> and <code>:utf-32be</code> implement UTF-32 with little-endian (<code>:utf-32le</code>) and big-endian (<code>:utf-32be</code>) byte order. The system maps them to one of <code>:utf-32-native</code> or <code>:utf-32-reversed</code> as appropriate.</p> <p><code>:utf-32</code> implements UTF-32 with control over the byte order. This format maps to one of <code>:utf-32-native</code> or <code>:utf-32-reversed</code> as appropriate. If <i>little-endian</i> is supplied, it determines the byte order. Otherwise, if it is used for opening a file, the system checks whether the file starts with the BOM (Byte Order Mark), and uses it if found. Otherwise the big-endian order is used. The system uses the required byte order and the native byte order of the computer it executes on to decide whether to use <code>:utf-32-native</code> or <code>:utf-32-reversed</code>.</p> <p>If the <code>:utf-32</code> formats encounter a surrogate code point or a character code which is too large, they by default signal an error of type <code>external-format-error</code>. If <i>use-replacement</i> is non-nil, they replace the illegal input by the replacement character. When <i>use-replacement</i> is non-nil these formats never signal an error.</p> <p>When writing, the <code>:utf-32</code> formats never signal an error.</p> |
| Compatibility notes | These formats were new in LispWorks 7.0. In LispWorks 6.1 and earlier versions there is an undocumented external format <code>character</code> that works similarly to <code>:utf-32-native</code> in LispWorks 7.0 and later. This is now mapped to <code>:utf-32-native</code> to avoid errors in existing code, and should not be used in new code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <code>char</code>  | The character whose code you wish to return.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                   |                                              |                  |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>set</code>   | A character set. Legal values for <code>set</code> are <code>:unicode</code> , <code>:latin-1</code> , <code>:ascii</code> , <code>:macos-roman</code> , <code>:jis-x-208</code> , <code>:jis-x-212</code> , <code>:euc-jp</code> , <code>:sjis</code> , <code>:koi8-r</code> , <code>:windows-cp936</code> and <code>:gbk</code> . Additionally, on Windows, <code>set</code> can be a valid Windows code page identifier.                                                                                                                                                                                                                                                                              |                   |                                              |                  |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values             | <code>code</code> The code of <code>char</code> in the character set <code>set</code> . An integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |                                              |                  |                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description        | <p>Returns the code of the character <code>char</code> in the coded character set specified by <code>set</code>, or <code>nil</code>, if there is no encoding. Note that a coded character set is not the same thing as an external format.</p> <p>For the <code>set</code> parameter, the <code>:jis-*</code> codes are KUTEN indexes (from the 1990 version of these standards) encoded as</p> <pre>(+ (* 100 row) column)</pre> <p><code>:euc-jp</code> is the complete two-byte format encoded as</p> <pre>(+ (* 256 first-byte) second-byte)</pre> <p><code>:sjis</code> is Shift-JIS encoded in the same way. Strictly speaking, EUC and Shift-JIS are not coded character sets, but encodings</p> |                   |                                              |                  |                                                                                                                                                                                                                                                                                                                                                                                                                             |

of the JIS sets, but the encoding is easily expressed as an integer, so the same interface to it is used.

| Description         | <p>The function <b><code>decode-lisp-string</code></b> decodes the integers in the part of the vector <code>vector</code> bounded by <code>start</code> and <code>end</code> using encoding <code>external-format</code> to make a string <code>string</code>.</p> <p>The element type of <code>vector</code> does not need to match the <code>external-format-foreign-type</code> of <code>external-format</code>.</p> |                                                     |
| Compatibility notes | This function exists in LispWorks 5.0 but is not documented and does not take the <code>:start</code> and <code>:end</code> arguments. Also, it was inefficient prior to LispWorks 5.0.1.                                                                                                                                                                                                                               |                                                     |

|---------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary             |                        | Converts a string to an encoded binary vector.                                                                                                                                                                                                                                                                                  |
| Package             |                        | <code>external-format</code>                                                                                                                                                                                                                                                                                                    |
| Signature           |                        | <code>encode-lisp-string string external-format &amp;key start end =&gt; vector</code>                                                                                                                                                                                                                                          |
| Arguments           | <i>string</i>          | A string.                                                                                                                                                                                                                                                                                                                       |
|                     | <i>external-format</i> | An external format spec.                                                                                                                                                                                                                                                                                                        |
|                     | <i>start, end</i>      | Bounding index designators of <i>string</i> .                                                                                                                                                                                                                                                                                   |
| Values              | <i>vector</i>          | A binary vector.                                                                                                                                                                                                                                                                                                                |
| Description         |                        | The function <code>encode-lisp-string</code> converts the part of <i>string</i> bounded by <i>start</i> and <i>end</i> to a binary vector <i>vector</i> encoded in encoding <i>external-format</i> .<br><br>The element type of <i>vector</i> matches the <code>external-format-foreign-type</code> of <i>external-format</i> . |
| Compatibility notes |                        | This function exists in LispWorks 5.0 but is not documented and does not take the <code>:start</code> and <code>:end</code> arguments. Also, it was inefficient prior to LispWorks 5.0.1.                                                                                                                                       |

|              |  | <i>Condition</i>                                                                                                      |
|--------------|--|-----------------------------------------------------------------------------------------------------------------------|
| Summary      |  | The condition class <code>external-format-error</code> is the super-class of all errors relating to external formats. |
| Package      |  | <code>external-format</code>                                                                                          |
| Superclasses |  | <code>error</code>                                                                                                    |

|             |                    |                                                                                                                                                                                                                                                                              |
|-------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initargs    | <code>:name</code> | The name of the external format involved.                                                                                                                                                                                                                                    |
| Description |                    | The class <code>external-format-error</code> provides a slot for the name of external format involved: this is the fully expanded form of the specification with all the parameters filled in. It is also useful for users who want to set up a handler for encoding errors. |

**external-format-foreign-type** *Function*

|             |                                                                                                                                                        |                                                                                         |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Summary     | Returns a type specifier for the integers handled by a specified external format.                                                                      |                                                                                         |
| Package     | <code>external-format</code>                                                                                                                           |                                                                                         |
| Signature   | <code>external-format-foreign-type external-format =&gt; type-specifier</code>                                                                         |                                                                                         |
| Arguments   | <code>external-format</code>                                                                                                                           | An external character format.                                                           |
| Values      | <code>type-specifier</code>                                                                                                                            | A type specifier describing the integer types handled by <code>external-format</code> . |
| Description | Takes the name of an external format, and returns a Lisp type specifier for the type of integers that the external format handles on the foreign side. |                                                                                         |
| See also    | <code>external-format-type</code>                                                                                                                      |                                                                                         |

|             |                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the character of a given code in a specified character set.                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Package     | <code>external-format</code>                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature   | <code>find-external-char code set =&gt; char</code>                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments   | <code>code</code>                                                                                                                                                            | A character code. This is an integer.                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <code>set</code>                                                                                                                                                             | A character set. Legal values for <code>set</code> are<br><code>:unicode</code> , <code>:latin-1</code> , <code>:ascii</code> , <code>:macos-roman</code> , <code>:jis-x-208</code> , <code>:jis-x-212</code> , <code>:euc-jp</code> , <code>:sjis</code> , <code>:koi8-r</code> , <code>:windows-cp936</code> and <code>:gbk</code> . Additionally, on Windows, <code>set</code> can be a valid Windows code page identifier. |
| Values      | <code>char</code>                                                                                                                                                            | The character represented by <code>code</code> . If <code>code</code> is not a legal code in the specified set, the return value is undefined.                                                                                                                                                                                                                                                                                 |
| Description | Returns the character that has the code <code>code</code> (an integer) in the coded character set specified by <code>set</code> , or <code>nil</code> , if that character is |                                                                                                                                                                                                                                                                                                                                                                                                                                |

not represented in the Lisp character set. Note that a coded character set is not the same thing as an external format.

For the `set` parameter, the `:jis-*` codes are KUTEN indexes (from the 1990 version of these standards) encoded as

```
(+ (* 100 row) column)
```

`:euc-jp` is the complete two-byte format encoded as

```
(+ (* 256 first-byte) second-byte)
```

`:sjis` is Shift-JIS encoded in the same way. Strictly speaking, EUC and Shift-JIS are not coded character sets, but encodings of the JIS sets, but the encoding is easily expressed as an integer, so the same interface to it is used.

## **valid-external-format-p** *Function*

Summary      Tests whether an external format spec is valid.

Package      `external-format`

Signature      `valid-external-format-p ef-spec &optional env => result`

Arguments      `ef-spec`      An external format spec.

`env`      An environment across which the spec should apply.

Values      `result`      A boolean.

Description      This predicate tests whether the external format spec given in `ef-spec` is valid (in the environment `env`).

`result` is `t` if `ef-spec` is a valid spec, and `nil` otherwise.

Example      `(valid-external-format-p '(:Unicode :eol-style :lf))`

# 38

## The HCL Package

This chapter describes symbols available in the `HCL` package. This package is used by default. Its symbols are visible in the `CL-USER` package.

Various uses of the symbols documented here are discussed throughout this manual.

|                                                              |                  |
|--------------------------------------------------------------|------------------|
| <code>add-code-coverage-data</code>                          |                  |
| <code>reverse-subtract-code-coverage-data</code>             |                  |

| <code>destructive-add-code-coverage-data</code>              |                  |
| <code>destructive-subtract-code-coverage-data</code>         |                  |
| <code>destructive-reverse-subtract-code-coverage-data</code> | <i>Functions</i> |

Summary      Add or subtract two `code-coverage-data` objects.

Package      `hcl`

Signature      `add-code-coverage-data ccd1 ccd2 name => new-ccd`  
`subtract-code-coverage-data ccd1 ccd2 name => new-ccd`

```

reverse-subtract-code-coverage-data ccd1 ccd2 name =>
new-ccd

destructive-add-code-coverage-data ccd1 ccd2 => ccd1

destructive-subtract-code-coverage-data ccd1 ccd2 => ccd1

destructive-reverse-subtract-code-coverage-data ccd1
ccd2 => ccd1

```

|             |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Arguments   | <i>ccd1</i>    | A <code>code-coverage-data</code> object or (for the non-destructive functions only) <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>ccd2</i>    | A <code>code-coverage-data</code> object or <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | <i>name</i>    | A Lisp object, normally a symbol or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <i>new-ccd</i> | A <code>code-coverage-data</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description |                | <p>Adding (subtracting) code coverage datas means adding (subtracting) all pairs of counters for the same piece of code from the two datas. When the data contains actual counters, adding (subtracting) really means adding (subtracting) the counter values, and reverse subtract means subtracting the first argument from the second. When the data contains only binary flags (that is, the code was compiled with <code>counters = nil</code>, see <code>generate-code-coverage</code>), addition is performed by doing logical OR, and subtraction by doing logical AND-NOT. Note that having counters is a property of each individual file, and a <code>code-coverage-data</code> object may have files that are compiled with either of these options.</p> <p>If <i>ccd1</i> or <i>ccd2</i> has value <code>t</code>, this is interpreted as the internal <code>code-coverage-data</code> object.</p> <p>These functions operate on each file in <i>ccd1</i> (first argument), and for each of these file for which there is a match in <i>ccd2</i>, perform the operation on all the counters of this file. That is, they add (subtract) the counter from <i>ccd2</i> to (from) the matching counter in <i>ccd1</i>. If there is no matching file in <i>ccd2</i>, the operation is done with 0 so the information from <i>ccd1</i> is used unchanged.</p> |

For files which have matches in *ccd2*, the information must be based on the same binary file, otherwise these functions signal an error.

The functions `add-code-coverage-data`, `subtract-code-coverage-data` and `reverse-subtract-code-coverage-data` all produce a new `code-coverage-data` object (with name *name*) which is the result of the operation. The functions `destructive-add-code-coverage-data`, `destructive-subtract-code-coverage-data` and `destructive-reverse-subtract-code-coverage-data` all overwrite *ccd1* with the result and return it.

For all these functions the result is a `code-coverage-data` object with information for each file for which there is information in *ccd1*, combined with the counters from *ccd2* for files with a match. Files in *ccd2* for which there is no match in *ccd1* are ignored.

|          |                                                                                                                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | For <code>reverse-subtract-code-coverage-data</code> and <code>destructive-reverse-subtract-code-coverage-data</code> the result for files with no match may be considered inconsistent, because negation their counters may be more consistent. |

| Values      | <i>function-list</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A list of the functions currently called to perform special actions, including the one just added. |
| Description | <p>When some objects are garbage collected, you may require a “special action” to be performed as well. <code>add-special-free-action</code> adds the function <i>function</i> to perform the special action. Note that the function is applied to all objects flagged for special-free-action, so the function <i>function</i> should check for the object’s type, so that it only affects relevant objects. Also, it should be fast when called with other objects.</p> <p>The functions <code>flag-special-free-action</code> and <code>flag-not-special-free-action</code> flag and unflag objects for action.</p> <p>When <i>function</i> is called, the object is still alive but is no longer flagged for special free action. Normally, the object will be collected on the next garbage collection cycle, but you can also store it somewhere which will prevent this. It may even be passed to <code>flag-special-free-action</code> again.</p> |                                                                                                    |
| Example     | <pre>(defun free-my-app (object)   (when (my-app-p object)     (free-some-external-resources object)))  (add-special-free-action 'free-my-app)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                    |

|             | <i>body</i>                                                                                                         | The forms to be evaluated while the allocation generation has been temporarily set to <i>gen-num</i> .                                                                                                                                                                                                             |
| Values      | <i>result</i>                                                                                                       | The result of evaluating body.                                                                                                                                                                                                                                                                                     |
| Description | Allocates objects from a specified generation during the extent of the evaluation of the body forms.                |                                                                                                                                                                                                                                                                                                                    |

Normally objects are allocated from the first (youngest) generation, which assumes that they are short-lived. The memory allocator and garbage collector perform better if allocation of large numbers of non-ephemeral objects is done explicitly into a generation other than the youngest.

**Notes** `allocation-in-gen-num` is implemented only in 32-bit LispWorks. In 64-bit implementations, use `apply-with-allocation-in-gen-num` or the `:allocation` argument to `make-array` instead.

**Examples**

```
(allocation-in-gen-num
  1
  (setq tab (make-hash-table :size 1200
                             :test 'eq)
        arr (make-array 20)))
```

## analysing-special-variables-usage *Function*

**Summary** Prints an analysis of proclaimed symbols seen during compilation, as an aid to improving declarations.

**Package** `hcl`

**Signature** `analyzing-special-variables-usage (&key all default maybe-globals maybe-dynamics unused only-bound wrong-global inconsistent stream) &body body => results`

**Arguments** `all` A boolean.

`default` A boolean.

| Description | <p>The macro <code>analyzing-special-variables-usage</code> executes the code in <i>body</i>, which needs to call the compiler, typically many times (compiling a whole system, for example). When <i>body</i> exits, it prints a simple analysis of symbols that were proclaimed and how they were proclaimed, in a way that is intended to be helpful in improving declarations. For a full explanation of how you might add or alter declarations, see “Usage of special variables” on page 113.</p> <p>The analysis is based solely on what the compiler sees, ignoring what is already in the image. It also ignores inline declarations.</p> <p>Only symbols for which the compiler sees a special proclamation are reported (including <code>cl:defvar</code>, <code>cl:defparameter</code>, <code>defglobal-parameter</code> and <code>defglobal-variable</code>, but not <code>cl:defconstant</code>).</p> <p><i>all</i> and <i>default</i> are convenience arguments to control groups of the other keyword arguments, which are all boolean flags. The default value of <i>all</i> is <code>nil</code>. <i>all</i> provides the default value of <i>maybe-globals</i> and <i>maybe-dynamics</i>. The default value of <i>default</i> is <code>t</code>. <i>default</i> provides the default value of <i>unused</i>, <i>only-bound</i>, <i>wrong-global</i> and <i>inconsistent</i>.</p> |                                      |

*stream* determines where the analysis goes, and is interpreted as if by `cl:format`. It does not affect any of the I/O in *body*. The default value of *stream* is `t`, meaning standard output.

*inconsistent* controls whether to print symbols where the declaration and usage is inconsistent. Inconsistencies include:

1. Accessing or binding the symbol before the proclamation.
2. Multiple declarations which are different (for example, change from `hcl:special-dynamic` to `cl:special`)

The *inconsistent* messages are the most useful. A well written program should not produce any such message.

*unused* controls whether to report symbols that are proclaimed special but are otherwise not used. For this option to be really useful, *body* needs to force compile many source files.

Since such unused variables do not affect the code, *unused* is normally useful only for finding and eliminating dead declarations, but it can also flag situations when the wrong variable is used (if the variable that is supposed to be used is not used elsewhere)

*only-bound* controls whether to report symbols that have been seen bound, but whose value has not been read. The comments about *unused* also apply to *only-bound*.

*wrong-global* controls whether to print symbols that are bound but are also proclaimed `hcl:special-global`. If the proclamation preceded the binding, the compiler will signal a `compiler-error`.

*maybe Globals* controls whether to report symbols that were not seen bound. If these symbols are really never bound, they can be proclaimed global by defining them with `defglobal-parameter` and `defglobal-variable`, or proclaimed `hcl:special-global`, both for speed and also to prevent them getting bound by mistake.

It is quite useful to force compile a program each now and then with *maybe-globals* true, then check through the report and proclaim global all those symbols that can be proclaimed global.

*maybe-dynamics* controls whether to report symbols that have been seen bound, and are proclaimed special, but not `hcl:special-dynamic` or `hcl:special-global`. Some of these may be proclaimed `hcl:special-dynamic`.

The report that is generated is grouped according to the file in which a proclamation was found. If a variable was proclaimed in multiple files, it will appear multiple times in the output. Within each file the output is grouped according to what is reported.

For the keyword arguments except *inconsistent*, the symbols are simply listed. For the *inconsistent* report, it outputs several lines for each symbol. Each line starts with one of the symbols `c1:special`, `hcl:special-global`, `hcl:special-dynamic`, `hcl:special-fast-access` (these four signify a proclamation), `:bound` or `:accessed` (these two indicate the usage). It is followed by the pathname of the file in which this one found. Only occurrences which give rise to inconsistency are listed.

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | The report about <i>inconsistent</i> usage is almost always useful. <i>unused</i> and <i>only-bound</i> are mostly useful when <i>body</i> force compiles many files, though they have limited utility in partial compilation too. <i>maybe-globals</i> and <i>maybe-dynamics</i> need full compilation to be really useful. Of the latter <i>maybe-globals</i> is the more useful. |

| Summary     |                     | Android only: Returns the value of a field in the <code>android.os.Build</code> Java class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## android-funcall-in-main-thread

## android-funcall-in-main-thread-list

*Functions*

Summary      Call a function on the Android main (GUI) thread.

Package      `hcl`

Signature      `android-funcall-in-main-thread func &rest args`

Signature      `android-funcall-in-main-thread-list func-and-args`

Arguments      `func`      A function designator.

`args`      Arguments for `func`.

`func-and-args`      A cons (`func . args`).

Description      The functions `android-funcall-in-main-thread` and  
`android-funcall-in-main-thread-list` arrange for the

function `func` to be applied to the `args` on the Android main thread (which is the GUI thread too). `android-funcall-in-main-thread` actually does it by consing `func` and `args` and calling `android-funcall-in-main-thread-list` with the result. `android-funcall-in-main-thread-list` is the "primitive" interface.

The invocation of the function is done by the event loop of the GUI thread, so it is synchronous with respect to processing events, in other words it will not happen in the middle of processing an event.

These functions should be used when `func` does something that needs to run on the main thread, most commonly operations that interact with GUI elements.

To allow for testing, these functions can be called on any architecture. On non-Android architectures, there is no "Android main process". In this case, `android-funcall-in-main-thread-list` first tests whether the variable `*android-main-process-for-testing*` is non-nil (which value must be a process), and if it is sends `func-and-args` to this process by `process-send`. This is based the assumption that this process processes cons events by applying the `c1:car` to the `c1:cdr`, which is the "normal" behavior of the system event processing (that is, what `general-handle-event` does). If you set this variable, make sure that this process processes events in this way. If `*android-main-process-for-testing*` is nil, `android-funcall-in-main-thread-list` arranges for the idle process to apply the `c1:car` to the `c1:cdr`.

#### Notes

`android-funcall-in-main-thread-list` always queues the function, even if it runs on the main thread. If you need to execute immediately when running on the main thread, check first using `android-main-thread-p`.

Chapter 16, “Android interface”

## **android-get-current-activity**                          *Function*

Summary      Return the current activity that was set by the Java method  
**com.lispworks.Manager.setCurrentActivity**.

Package      **hcl**

Signature      **android-get-current-activity** => **result**

Arguments      None.

Values      **result**      An object of class **android.app.Activity**,  
or **nil**.

Description      The function **android-get-current-activity** returns the current activity that was set by the Java method **com.lispworks.Manager.setCurrentActivity**, if the current thread is the Android main thread.

**android-get-current-activity** first checks whether the current thread is the main thread, and if it is not returns **nil**. Otherwise, it returns the activity that was last set by **com.lispworks.Manager.setCurrentActivity** (an object of class **android.app.Activity**). This is the object that is needed to create dialogs.

Notes      The main purpose of **android-get-current-activity** is to decide whether the current code can raise dialogs, and if so to get the activity to use as a context.

Examples      (**example-edit-file "android/dialog"**)

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Variable defining the "Android main process" when not running on Android.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description   | <p>The variable <code>*android-main-process-for-testing*</code> defines the "Android main process" when not running on Android.</p> <p><code>*android-main-process-for-testing*</code> defaults to <code>nil</code>. If it is set, it must be a <code>mp:process</code> object, which processes events which are a cons by applying the <code>c1:car</code> to the <code>c1:cdr</code>.</p> <p><code>*android-main-process-for-testing*</code> is used by <code>android-funcall-in-main-thread-list</code> and <code>android-funcall-in-main-thread</code> when they are called on non-Android platforms.</p> |
| Notes         | <p><code>general-handle-event</code> processes conses by applying the <code>c1:car</code> to the <code>c1:cdr</code>, and therefore any process that uses it to process events will do the right thing. That includes the CAPI events loop, and users of <code>wait-processing-events</code> and <code>process-all-events</code>.</p>                                                                                                                                                                                                                                                                         |

## android-main-thread-p Function

**Summary** Tests whether the current thread is the Android main (GUI) thread.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |

|             |                                                                                                                                                      | <i>Function</i> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary     | A predicate for whether any CAPI window is currently displayed.                                                                                      |                 |
| Package     | <code>hcl</code>                                                                                                                                     |                 |
| Signature   | <code>any-capi-window-displayed-p =&gt; result</code>                                                                                                |                 |
| Values      | <code>result</code>                                                                                                                                  | A boolean.      |
| Description | <p>The function <code>any-capi-window-displayed-p</code> is a predicate for whether any CAPI window (other than dialogs) is currently displayed.</p> |                 |

- Notes
1. See the *CAPI User Guide and Reference Manual* for a description of the CAPI toolkit which allows you to write graphical user interfaces in Lisp.
  2. Tools in the LispWorks IDE are all CAPI windows.

## **array-single-thread-p** *Function*

Summary      The predicate for single-thread arrays.

Package      **hcl**

Signature      **array-single-thread-p array => result**

Arguments      **array**                  An array.

Values      **result**                  A boolean.

Description      The function **array-single-thread-p** is the predicate for whether an array is one known to be only accessed in a single thread context, as created by

(make-array ... :single-thread t)

or set by **set-array-single-thread-p**.

See also      **make-array**  
**set-array-single-thread-p**

## **array-weak-p** *Function*

Summary      The predicate for whether an object is a weak array.

Package      **hcl**

Signature      **array-weak-p object => result**

|             |               |                                                                                                                                     |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>object</i> | A Lisp object.                                                                                                                      |
| Values      | <i>result</i> | A boolean.                                                                                                                          |
| Description |               | The function <b>array-weak-p</b> returns <b>t</b> if its argument <i>object</i> is a weak array, and otherwise returns <b>nil</b> . |
| See also    |               | <b>make-array</b><br><b>set-array-weak</b>                                                                                          |

## **augment-environment** *Function*

**Summary** Returns a new environment based on an existing one with different bindings.

**Package** **hcl**

**Signature** **augment-environment** *env* &**key** *variable symbol-macro function macro declare reset => newenv*

|           |                     |                                  |
|-----------|---------------------|----------------------------------|
| Arguments | <i>env</i>          | An environment or nil            |
|           | <i>variable</i>     | A list of symbols                |
|           | <i>symbol-macro</i> | A list of lists                  |
|           | <i>function</i>     | A list of function names         |
|           | <i>macro</i>        | A list of lists                  |
|           | <i>declare</i>      | A list of declaration-specifiers |
|           | <i>reset</i>        | A generalized boolean            |

**Values** *newenv* An environment

**Description** The function **augment-environment** returns a new environment *newenv*, based on *env* but modified according to the keyword arguments *variable*, *symbol-macro*, *function*, *macro*, *declare* and *reset*.

If *env* is `nil`, then *newenv* will be based on the null environment. Otherwise, if *reset* is false (the default) then all of the bindings in *env* will be present in *newenv* unless overridden by the other keyword arguments. Otherwise, if *reset* is true then all of the non-local bindings in *env* will be present in *newenv* but none of the local bindings will be present. Passing *reset* as true allows you to create an environment object for calls to `variable-information` and so on which can access the file compilation environment without seeing local bindings in the lexical environment.

*variable* should be a list of symbols and *newenv* will contain these symbols as local variable bindings. A binding will be a special binding if the symbol is declared special non-lexically in *env* or a special declaration is present in `declare`.

*symbol-macro* should be a list of lists of the form (*symbol expansion*) and *newenv* will contain local symbol-macro bindings for each *symbol* with *expansion* as its macroexpansion.

*function* should be a list of function names and *newenv* will contain these symbols as local function bindings.

*macro* should be a list of lists of the form (*symbol macrofunction*) and *newenv* will contain local macro bindings for each *symbol* with *macrofunction* as its macroexpansion function. Each *macrofunction* is a function of two arguments, a form and an environment, which should return the expanded form.

*declare* should be a list of declaration-specifiers, which will be added to *newenv* as if by `declare`.

It is an error to use a symbol in *symbol-macro* that is also in *variable* or is declared special.

It is an error to use a symbol in *macro* that is also in *function*.

*newenv* has the same extent as *env*, that is it might have dynamic extent within the function that created *env*.

The lists passed to `augment-environment` should be not destructively modified afterwards.

Notes      `augment-environment` is part of the environment access API which is based on that specified in *Common Lisp: the Language (2nd Edition)*.

## **avoid-gc** *Function*

|             |                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Avoids garbage collection if possible in 32-bit LispWorks.                                                                                                                                                                                                                                                    |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                              |
| Signature   | <code>avoid-gc =&gt; previous-results</code>                                                                                                                                                                                                                                                                  |
| Arguments   | None.                                                                                                                                                                                                                                                                                                         |
| Values      | The function returns the previous settings of <code>minimum-for-sweep</code> , <code>maximum-overflow</code> and <code>minimum-overflow</code> . (see <code>set-gc-parameters</code> for details of these.)                                                                                                   |
| Description | <p><code>avoid-gc</code> sets various internal parameters so that garbage collection is avoided as far as possible.</p> <p>This can be useful with non-interactive programs.</p> <p>If you use <code>avoid-gc</code>, use <code>normal-gc</code> later to reset the parameters to their default settings.</p> |
| Notes       | <code>avoid-gc</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit imple-                                                                                                                                                                               |

mentations. In 64-bit implementations, you can use `set-default-segment-size` to increase the default size of segments in the lower generations (typically generations 0 and 1). This will lead to less frequent garbage collections.

**\*background-input\*****\*background-output\*****\*background-query-io\*****Variables**

Summary Default streams for the standard streams.

Package `hcl`

Initial value The value of `cl:*terminal-io*`.

Description The variables `*background-input*`, `*background-output*` and `*background-query-io*` are default streams for the standard Common Lisp streams.

These variables are all set to the value of `cl:*terminal-io*` when the image starts, but when the LispWorks IDE starts it sets:

- `*background-output*` to `mp:*background-standard-output*`.
- `*background-input*` to a stream that always returns EOF.
- `*background-query-io*` to a stream that interacts with the user using CAPI prompters.

The default value of each of the standard streams is a synonym stream to a `*background-*` stream:

- `*standard-input*` is a synonym to `*background-input*`.
- `*standard-output*`, `*trace-output*` and `*error-output*` are synonyms to `*background-output*`.
- `*query-io*` and `*debug-io*` are synonyms to `*background-query-io*`.

Thus when the LispWorks IDE is running, output to the standard output streams goes to the `mp:*background-standard-output*`, and can be viewed in the **Output** tab of the Listener and Editor windows, and the Output Browser tool. Trying to read from `*standard-input*` once the environment is running returns EOF. Using `*query-io*` causes on-screen prompting.

The main purpose of these variables is to redirect the standard input and output streams once the LispWorks IDE is running, because writing to `cl:*terminal-io*` is not useful in most cases.

You can set or rebind these variables if required, and this changes the default destination of the standard streams.

#### Notes

Processes that are created by CAPI for an interface while the IDE is running rebinding the standard input, output and query I/O streams to themselves (so setting them in these processes does not change the global value). This does not happen on processes that are not created by CAPI, and does not happen when the LispWorks IDE is not running, in particular in delivered applications. When the LispWorks IDE is running, the output to standard output stream on other processes will still go by default to the `mp:*background-standard-output*`, because `*background-output*` is set to it.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility note | These variables were new in LispWorks 7.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                    | In LispWorks 6.1 and earlier versions, CAPI processes in the LispWorks IDE bound the output streams to <code>mp:*background-standard-output*</code> , the standard input to a stream that returns EOF and <code>*QUERY-IO*</code> to a stream that interacts with the user using CAPI prompters. Hence, for these processes, the default behavior has not changed. However input and output on other processes was going to/from the <code>c1:*terminal-io*</code> by default, which caused various problems. The main purpose of these variables is to fix these problems. |

| Summary     | Prevents promotion of objects into generation 2 during the execution of <i>body</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                          |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                          |
| Signature   | <code>block-promotion &amp;body body =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                          |
| Arguments   | <i>body</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Forms executed as an implicit <code>progn</code> .       |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | The result of evaluating the final form in <i>body</i> . |
| Description | <p>The macro <code>block-promotion</code> executes <i>body</i> and prevents promotion of objects into generation 2 during this execution. After <i>body</i> is executed, generations 0 and 1 are collected.</p> <p>This is useful when a significant number of transient objects actually survive all the garbage collections on generation 1. These would normally then be promoted and, by default, never get collected. In such a situation, <code>(gc-generation t)</code> will free a large amount of space in generation 2.</p> <p><code>block-promotion</code> can be thought of as doing <code>set-promotion-count</code> on generation 1 with an infinite <i>count</i>, for the duration of <i>body</i>.</p> <p><code>block-promotion</code> is suitable only for use in particular operations that are known to create such relatively long-lived, but transient, objects. In typical uses these are objects that live for a few seconds to several hours. An example usage is Lisp-Works <code>compile-file</code>, to ensure the transient compile-time data gets collected.</p> |                                                          |

**block-promotion** has global scope and hence may not be useful in an application such as a multithreaded server. During the execution of *body*, generation 1 grows to accommodate all the allocated data, which may have some negative effects on the behavior of the system, in particular on its interactive response.

- Notes
1. Symbols and process stacks are allocated in generation 2 or 3 (see `*symbol-alloc-gen-num*`) hence **block-promotion** cannot prevent these getting into that generation. `allocation-in-gen-num` can also cause allocation in higher generations.
  2. In 64-bit LispWorks, **block-promotion** is implemented using `set-blocking-gen-num`.

## **building-universal-intermediate-p** *Function*

- Summary      Deprecated. Simply returns `nil`.
- Package      `hcl`
- Signature      `building-universal-intermediate-p => intermediatep`
- Arguments      None
- Values      *intermediatep*      A boolean.
- Description      The function **building-universal-intermediate-p** is deprecated. The return value *intermediatep* is `nil`.
- Compatibility note      In LispWorks 6.1 for Macintosh and earlier versions, **building-universal-intermediate-p** is used in a build script to

determine whether LispWorks is building an intermediate image when making a universal binary.

In LispWorks 7.0 and later versions universal binaries are not supported, and this function always returns `nil`, on all platforms.

|-------------------------|-----------------------------------------------------------|-----------------------------------------------------|
| Summary                 | Changes the current directory.                            |                                                     |
| Package                 | <code>hcl</code>                                          |                                                     |
| Signature               | <code>change-directory directory =&gt; current-dir</code> |                                                     |
| Arguments               | <code>directory</code>                                    | A pathname designator specifying the new directory. |
| Values                  | <code>current-dir</code>                                  | A physical pathname.                                |

|             |                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <code>change-directory</code> changes the current directory to that specified by <i>directory</i> . <i>directory</i> may be an absolute or relative pathname. |
|             | Use <code>get-working-directory</code> to find the current directory.                                                                                         |
| Notes       | <code>change-directory</code> should not be used in multithreaded applications. In general we discourage you from using it.                                   |
| See also    | <code>cd</code><br><code>get-working-directory</code>                                                                                                         |

|           | <i>Function</i>                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Provides information about the fragmentation in a generation in 32-bit LispWorks.                                                                                                                                                                                                                                            |
| Package   | <code>hcl</code>                                                                                                                                                                                                                                                                                                             |
| Signature | <code>check-fragmentation gen-num =&gt; total-free, total-small-blocks, total-large-blocks</code>                                                                                                                                                                                                                            |
| Arguments | <p><i>gen-num</i>      0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error.</p>                                                                                                                                       |
| Values    | <p><i>total-free</i>      Total free space in the generation.</p> <p><i>total-small-blocks</i> Amount of free space in the generation which is available in blocks of 512 bytes or larger.</p> <p><i>total-large-blocks</i> Amount of free space in the generation which is available in blocks of 4096 bytes or larger.</p> |

|             |                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The latter two values give indication of the level of fragmentation in the generation. This information can be used, for example, to decide whether to call <code>try-move-in-generation</code> .                                   |
| Notes       | <code>check-fragmentation</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations, where <code>gen-num-segments-fragmentation-state</code> is available instead. |

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Frees memory and reduces the size of the image, if possible.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>clean-down &amp;optional full =&gt; new-size</code>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments   | <code>full</code> A generalized boolean.<br><code>new-size</code> A positive integer.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description | <p>Tries to free as much memory as possible and then reduce the size of the image as much as possible, and also move all the allocated objects to an old generation.</p> <p><code>full</code> controls whether to operate on the highest generation. The default value of <code>full</code> is <code>t</code>.</p> <p>If <code>full</code> is <code>t</code>, <code>clean-down</code> does a mark and sweep on generation 3, promotes all the objects into generation 3, deletes the</p> |

empty segments and tries to reduce the image size. This is called by default before saving an image.

If *full* is `nil`, `clean-down` does a mark and sweep on generation 2, promotes all the objects to generation 2 and tries to reduce the size of all generations up to 2, but does not touch generation 3.

`clean-down` returns the new size of the Lisp image after reduction, in bytes.

`clean-down` may fail to delete empty segments if there are static segments in high address space.

#### Notes

1. `try-move-in-generation` (which is implemented only in 32-bit LispWorks) uses less CPU than `clean-down`, though it does not do the mark and sweep.
2. In 64-bit LispWorks, `clean-down` is implemented as if by `(gc-generation 7 :coalesce t)` though you can use `gc-generation` directly for better control.
3. In the Mobile GC, `clean-down` performs the same GC as `(gc-generation t)`.
4. `clean-down` may temporarily increase memory usage, and when called with *full* `nil` may result in a larger Lisp image (though better organized, and therefore behaving better). In 32-bit LispWorks in situations where it is important not to increase memory usage, such as when the operating system signals that memory is low, use `reduce-memory` instead.

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Attempts to promote all objects from generation zero into generation one, thereby clearing generation zero, in 32-bit LispWorks.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Signature   | <code>clean-generation-0 =&gt; 1</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments   | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Values      | Returns the value 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description | This is useful when passing from a phase of creating long-lived data to a phase of mostly ephemeral data, for example, the end of loading an application and the start of its use.                                                                                                                                                                                                                                                                                                                                                     |
| Notes       | <ol style="list-style-type: none"> <li>1. The function may not be very useful, as it may be more efficient to directly allocate the objects in a particular generation in the first place, using <code>allocation-in-gen-num</code> or <code>set-default-generation</code>.</li> <li>2. <code>clean-generation-0</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where the same effect can be obtained by a call <code>(gc-generation 0)</code>.</li> </ol> |
| Example     | <pre>;   allocate lots of non-ephemeral objects ;   ..... (clean-generation-0)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| See also    | <code>allocation-in-gen-num</code><br><code>collect-generation-2</code><br><code>collect-highest-generation</code><br><code>expand-generation-1</code><br><code>gc-generation</code>                                                                                                                                                                                                                                                                                                                                                   |

**set-promotion-count**

“Memory Management in 32-bit LispWorks” on page 135

**clear-code-coverage**

**reset-code-coverage**

**restore-code-coverage-data**

*Functions*

Summary      Modify the internal **code-coverage-data** object.

Package      **hcl**

Signature      **clear-code-coverage => result**  
**reset-code-coverage => result**  
**restore-code-coverage-data code-coverage-data &key error => result**

Arguments      **code-coverage-data**

                  A **code-coverage-data** object.

**error**            :warn, nil or t.

Value            **result**        A boolean.

Description      The function **clear-code-coverage** clears the internal **code-coverage-data** object, which means removing all the files from it, so that their counters are not accessible anymore. Note that it does not actually remove the counters from the code.

The function **reset-code-coverage** resets all the counters in the internal **code-coverage-data** object to 0.

The function **restore-code-coverage-data** sets the counters of all files that appear in both the internal code coverage data and the argument **code-coverage-data** to the counters in the **code-coverage-data** argument. All these files

need to have the same code coverage code, that is they must be based on the same binary file.

`error` controls what happens for files that do not have the same code coverage code. Value `:warn` means warn and continue, `:nil` means quietly skip it, and `t` means signal an error. `restore-code-coverage-data` never restores a file with no matching code coverage code. The default value of `error` is `:warn`.

The value of `result` indicates whether there was an internal `code-coverage-data` object when the function was called.

#### Notes

1. If `error` is `t`, some of the files would be restored and some not, leaving the internal `code-coverage-data` object in an inconsistent state.
2. All these functions also reset any snapshot by calling `reset-code-coverage-snapshot`.

|             |                                                                                                                                                                                                                                                                                                                                                                                            | Type |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Summary     | A structure containing information about code coverage.                                                                                                                                                                                                                                                                                                                                    |      |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                           |      |
| Readers     | <code>code-coverage-data-name</code><br><code>code-coverage-data-create-time</code>                                                                                                                                                                                                                                                                                                        |      |
| Description | <p>The type <code>code-coverage-data</code> is a structure containing information about code coverage.</p> <p><code>code-coverage-data</code> contains information about some set of files. With the exception of the internal code coverage data, <code>code-coverage-data</code> does not change after it is created. The internal code coverage data contains information about all</p> |      |

files that have been loaded with code coverage (since the last call to `clear-code-coverage`). A file is "with code coverage" when it is a binary file compiled with code coverage on (see `generate-code-coverage`).

The counters in the internal code coverage data are the counters that the actual code is referencing, and therefore they are modified whenever any of this code is executing. For each file the counters are either actual counters or binary flags (see *counters* argument in `generate-code-coverage`), but inside the structure there may be files of either counter type.

All other `code-coverage-data` structures start their life as copies of the internal code coverage data, and then they can be further manipulated. They are displayed by `code-coverage-data-generate-coloring-html` or the LispWorks IDE.

The *name* is supplied to the data when it is created by functions like `copy-current-code-coverage`, and the *create-time* is the universal time when the data was created. These values are provided so that you can track your data: they are not used by the system. *name* can be any Lisp object, but normally should be a symbol or a string (because if you save the data name will be written too, so it is best if does not point to a large structure).

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>code-coverage-data-generate-coloring-html</code> generates HTML showing the code coverage.</p> <p><i>target</i> specifies the directory for the HTML files, and optionally the name of the index file, if <i>target</i> has a name component and <i>index-filename</i> is not supplied.</p> <p><i>code-coverage-data</i> must be a <code>code-coverage-data</code> object to use. Otherwise <code>code-coverage-data-generate-coloring-html</code> uses the internal data.</p> <p><i>shared-source-directory</i> must specify a directory path. It has two effects:</p> <ul style="list-style-type: none"> <li>• HTML is produced only for source files in the <i>shared-source-directory</i> (the <i>filter</i> may exclude some of these), and</li> <li>• The path of each HTML file is constructed from the relative path of the source file with respect to the <i>shared-source-directory</i> (as produced by <code>c1:enough-namestring</code>) merged with the <i>target</i> directory. The result is a tree of HTML files which is parallel to the tree of the source files.</li> </ul> <p>If <i>shared-source-directory</i> is not supplied, all files that passed the <i>filter</i> are produced, and the target HTML file has the filename of the source file inside the <i>target</i> directory. Note that this may cause clashes if there are files with the same name in the data.</p> <p><i>filter</i> can be used to restrict which files HTML is produced for. If <i>filter</i> is a string it is interpreted as a regexp. If the <code>c1:namestring</code> of the truename of a source file matches <i>filter</i> (as by <code>find-regexp-in-string</code>) then HTML is produced for this source file. If <i>filter</i> is a function (or fbound symbol) it must take two arguments, the truename and the <code>code-coverage-file-stats</code> for this source file, and return a boolean specifying whether to produce HTML for this source file. The <code>stats</code> object can be accessed by the <code>code-coverage-file-stats</code> accessor functions (for example <code>code-coverage-file-stats-lambdas-count</code>). If <i>filter</i> is not supplied, all</p> |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

files (or, if *shared-source-directory* is supplied, all those files inside it) are produced.

*target-type* specifies the type of the output files. The default value of *target-type* is "htm".

*color-uncovered*, *color-covered*, *show-counters* and *counter-space* control the HTML output. See "Source files HTML coloring" below for details. Note that the colors to actually use are specified by `code-coverage-set-html-background-colors`.

*color-uncovered* controls whether uncovered forms are colored. These include forms that did not execute at all, eliminated forms and forms which were partially executed but the unexecuted part is hidden (in a macroexpansion). The default value of *color-uncovered* is t.

*color-covered* controls whether covered forms are colored. These include forms that were fully executed, and those parts of partially executed forms that were executed. The default value of *color-covered* is nil.

*show-counters* controls whether to insert counters in the HTML. The default value of *show-counters* is t.

*counter-space* specifies whether to insert a space before and/or after each counter. The value t has the same meaning as :both. The default value of *counter-space* is :after.

*index-filename*, *index-name*, *index-sort*, *index-mark-not-entered*, *index-mark-partial* and *index-show-non-runtime* control the generation of the index file. See "Index file" below for the description of the index file's contents.

*index-filename*, when supplied, specifies the name of the index file. It is merged with the *target* path to generate the full path. Note that the file type should be included in either *index-filename* or the *target* path. If *index-filename* is not supplied, it defaults to "`code-coverage-index.htm`". If *index-filename* is nil, no index file is produced.

*index-name* is printed (with format directive `~A`) as part of the title of the index file, and not used otherwise. The default value of *index-name* is "Index".

*index-sort* controls the order files are listed in the table in the index. `:relative-name` means sort by the relative name of the source file with respect to *shared-source-directory*. If *shared-source-directory* is not supplied, `:relative-name` has the same effect as `:name`. `:name` means sort by the name of the source file. `:uncovered` means sort by the number of not fully covered run time lambdas in the file (the sum of `code-coverage-file-stats-not-called` and `code-coverage-file-stats-partially-covered` called with `:runtime`). The default value of *index-sort* is `:relative-name`.

*index-mark-not-entered* controls whether to mark cells in the run time part for uncovered lambdas. The default value of *index-mark-not-entered* is `t`.

*index-mark-partial* controls whether to mark cells in the run time part for lambdas that are partially covered. The default value of *index-mark-partial* is `t`.

*index-show-non-runtime* controls whether to show the non-run time part of the table. The default value of *index-show-non-runtime* is `t`.

*open* specifies whether the index file should be opened (by `open-url`) once it is generated. The default value of *open* is `nil`.

## The HTML output

`code-coverage-data-generate-coloring-html` generates a HTML file for each source file in *code-coverage-data* that is inside the *shared-source-directory* (or all source files if *shared-source-directory* is `nil`) and pass the *filter* (or all if *filter* is `nil`), as described above, and one index file with statistics. It uses background colors to mark various things (see below), and these colors can be set by `code-coverage-set-html-back-`

`ground-colors`. The colors that are described below are the default colors.

## Index file

The index file contains a table with a single row per file.

The first column shows the file "relative name", which is relative to the optional `shared-source-directory`, or just the filename. The rest of the columns contain statistics, which are divided into 2 parts: run time lambdas and optional non-run time lambdas. "Lambda" here means a separate piece of code (for example code that is called inline does not count as a separate lambda). Run time lambdas refer to code that is expected to run at run time, which includes things like functions and methods. Non-run time lambdas are other lambdas, like macros and top-level forms (as known as one-shot forms). More accurately, run time and non-run time refer to the counts which are returned by the `code-coverage-file-stats` accessor functions (for example `code-coverage-file-stats-lambdas-count`) when they are called with `:runtime` or `:non-runtime`. See `code-coverage-file-stats` for details.

The run time and the non-run time parts each contain 4 columns:

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| Total   | The total number of lambdas, as returned by <code>code-coverage-file-stats-lambdas-count</code> .                           |
| Full    | The number of lambdas that were fully covered, as returned by <code>code-coverage-file-stats-fully-covered</code> .         |
| Partial | The number of lambdas that were partially covered, as returned by <code>code-coverage-file-stats-partially-covered</code> . |

None            The number of lambdas that were not covered, as returned by `code-coverage-file-stats-not-called`.

In the run time columns, Partial and None cells which are non-zero are optionally marked with a colored background. This helps you to see which files contain run time forms that were not executed. The default color is DarkSalmon, and this can be set by `code-coverage-set-html-background-colors` with keyword argument *marked-cell*.

## Source files HTML coloring

The HTML file corresponding to a source file contains the full text of the source file (including comments), with parts optionally highlighted by background colors, and optional counters and some text added. At the time of writing, the default behavior is to highlight uncovered forms and add counters. The background colors can be changed by `code-coverage-set-html-background-colors`. The general issues associated with coloring are covered in “Understanding the code coverage output” on page 124.

Notes        If no file containing code coverage code was loaded, there is no internal data, so if `code-coverage-data` is not supplied then `code-coverage-data-generate-coloring-html` signals an error.

## `code-coverage-data-generate-statistics`

## *Function*

Summary     Generates statistics about code coverage.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Arguments   | <p><code>code-coverage-data</code><br/> A <code>code-coverage-data</code> object.</p> <p><code>sort</code><br/> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values      | <p><code>result</code><br/> A vector of <code>code-coverage-file-stats</code> objects.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description | <p>The function <code>code-coverage-data-generate-statistics</code> generates statistics about code coverage.</p> <p><code>code-coverage-data</code>, if supplied, must be a <code>code-coverage-data</code> object, otherwise the internal <code>code-coverage-data</code> object is used. For each file in the data, <code>code-coverage-data-generate-statistics</code> generates a <code>code-coverage-file-stats</code> object. It returns a vector of these <code>code-coverage-file-stats</code> objects.</p> <p>If the argument <code>sort</code> is non-nil (the default), the vector is sorted by the <code>cl:file-namestring</code> of the source file.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. The stats objects do not change after <code>code-coverage-data-generate-statistics</code> returns, even if the data that was used is the internal one.</li> <li>2. The statistics are only coverage, that is they treat the counters as binary zero/non-zero values. That includes negative counters (which may occur if the supplied data is a result of subtraction), which counted as "Covered".</li> <li>3. The stats objects can be accessed by the <code>code-coverage-file-stats</code> readers.</li> </ol>                                                                                                            |

| Summary        | A structure containing code coverage statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Package        | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Readers        | <code>code-coverage-file-stats-source-file</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Description    | Objects of type <code>code-coverage-file-stats</code> are created by <code>code-coverage-data-generate-statistics</code> , and are then accessed by the readers.<br><br><code>code-coverage-file-stats-source-file</code> returns the true-name of the source file. The pseudo-readers return integers counting "lambdas" in this file, where "lambda" here means a separate function object that was produced by the compiler. In most cases these correspond to pieces of code that you can see, like a function that results from <code>cl:defun</code> or <code>cl: defmethod</code> , or a lambda that appears in your code, but in some cases the compiler generates functions in a non-obvious way.<br><br>The pseudo-readers each have signature<br><br><code>pseudo-reader ccfs keyword =&gt; count</code><br><br>where <code>ccfs</code> is a <code>code-coverage-file-stats</code> object, and <code>keyword</code> specifies the kind of lambda. All lambdas belong to one of these four kinds:<br><br><code>:functions</code> Functions that are defined by <code>cl:defun</code> . |

|                        |                                                               |
|------------------------|---------------------------------------------------------------|
| <code>:macros</code>   | Macros and macro-like (for example <code>cl:defsetf</code> ). |
| <code>:one-shot</code> | Load time lambdas that the compiler generates.                |
| <code>:lambdas</code>  | Other lambdas (including <code>cl:defmethod</code> ).         |

In addition, the following three values of *keyword* can be used:

|                           |                                                     |
|---------------------------|-----------------------------------------------------|
| <code>:all</code>         | All lambdas.                                        |
| <code>:runtime</code>     | <code>:functions</code> and <code>:lambdas</code> . |
| <code>:non-runtime</code> | <code>:one-shot</code> and <code>:macros</code> .   |

Each pseudo-reader returns the number of lambdas or counters in the file of the kind specified by the *keyword*. These are:

|                                                         |                                                                                                                       |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>code-coverage-file-stats-lambdas-count</code>     | All lambdas.                                                                                                          |
| <code>code-coverage-file-stats-called</code>            | Lambdas that have been called.                                                                                        |
| <code>code-coverage-file-stats-fully-covered</code>     | Lambdas which were fully covered, that is all of their counters are non-zero.                                         |
| <code>code-coverage-file-stats-hidden-covered</code>    | Lambdas where there are counters which are 0, but do not correspond to actual source code (result of macroexpansion). |
| <code>code-coverage-file-stats-not-called</code>        | Lambdas that were not called at all.                                                                                  |
| <code>code-coverage-file-stats-partially-covered</code> | Lambdas that were partially covered, but part of the source did not execute.                                          |
| <code>code-coverage-file-stats-counters-count</code>    |                                                                                                                       |

All counters.

**code-coverage-file-stats-counters-executed**

Counters that executed (that is, they are not zero).

**code-coverage-file-stats-counters-hidden**

Counters which have not been executed and are hidden, that is not in the source (in a result of macroexpansion).

Notes

1. The statistics are based on interpreting the counters as a binary switch of zero/non-zero. Negative counter values (which may occur if the code coverage data is a result of a subtraction operation such as `subtract-code-coverage-data`) are interpreted as "executed".
2. The run time/non-run time distinction is intended to correspond to code that would run in the actual application (run time) and code that is used only at compile-time or load-time.

Examples

```
code-coverage-file-stats-called code-coverage-file-stats
:runtime
=>
lambda-count
```

where *lambda-count* is the number of lambdas in the file which are "run time" and have been called.

| Description              | <p>The function <code>code-coverage-set-editor-colors</code> changes the colors or faces that the editor uses to color code coverage. Each argument is a CAPI color name, color alias or color specification, or an <code>editor:face</code> object (the result of <code>editor:make-face</code>). See "The Color System" in the <i>CAPI User Guide and Reference Manual</i> for details about CAPI colors.</p> <p>When an argument value is an <code>editor:face</code>, it specifies the face to use. Otherwise, it specifies the background color to use.</p> <p>The faces and colors are used to color parts of the code as in <code>code-coverage-set-html-background-colors</code>. Note that <code>code-coverage-set-editor-colors</code> does not accept a <code>:marked</code> keyword argument like <code>code-coverage-set-html-background-colors</code> does.</p> |                 |                                 |                          |                                 |                  |                                 |                          |                                 |                      |                                 |                       |                                 |              |                                 |             |                                 |                   |                                 |

| Description                                     | <p>The function <code>code-coverage-set-html-background-colors</code> sets the background colors that <code>code-coverage-data-generate-coloring-html</code> uses to color the output.</p> <p>Each of the keyword arguments, when supplied, must specify a color that is valid HTML. This can be either:</p>                                                                           |

- A hexadecimal value "#RRGGBB" where RR, GG and BB are hexadecimal numbers specifying the Red, Green and Blue values, or
- A name that web browsers recognize.

LispWorks does not actually check that the name is a known name.

Only those colors for which a keyword argument is supplied are affected.

See “Understanding the code coverage output” on page 124 for details of how the colors are used.

| Summary     | Controls whether generation 2 is garbage collected in 32-bit LispWorks.                                                   |                                                                                                                                                             |
| Package     | <code>hcl</code>                                                                                                          |                                                                                                                                                             |
| Signature   | <code>collect-generation-2 on =&gt; size</code>                                                                           |                                                                                                                                                             |
| Arguments   | <code>on</code>                                                                                                           | If <code>on</code> is <code>nil</code> , generation 2 is not garbage collected. If <code>on</code> is <code>t</code> , the generation is garbage collected. |
| Values      | <code>size</code>                                                                                                         | The current size of the image.                                                                                                                              |
| Description | Controls whether generation 2 is garbage collected. (Generation 2 normally holds long-lived objects created dynamically.) |                                                                                                                                                             |

|          |                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>collect-generation-2</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where you can use <code>set-blocking-gen-num</code> instead.                                                                                                   |

**\*compiler-break-on-error\*** *Variable*

Summary Controls whether `compile-file` handles compilation errors.

Package `hcl`

Initial value `nil`

Description If an error occurs during compilation of a form by `compile-file`, an error handler normally causes the compilation of that form to be skipped, and the error is reported later.  
When `*compiler-break-on-error*` is non-nil, an error during compilation by `compile-file` is signaled and the debugger is entered.

See also `compile-file`

**compile-file-if-needed** *Function*

Summary Compiles a Lisp source file if it is newer than the corresponding fasl file.

Package `hcl`

Signature `compile-file-if-needed input-pathname &key output-file load &allow-other-keys => output-truename, warnings-p, failure-p`

Arguments `input-pathname` A pathname designator.

|             |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|             | <i>failure-p</i>       | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                        | <p>The function <code>compile-file-if-needed</code> compares the <code>file-write-date</code> of the source file named by <i>input-pathname</i> with the <code>file-write-date</code> of the appropriate fasl file (as computed by <code>compile-file-pathname</code> from <i>input-pathname</i> and <i>output-file</i>).</p> <p>If the fasl file does not exist or is older than <i>input-pathname</i>, then <code>compile-file</code> is called with <i>input-pathname</i>, <i>output-file</i>, <i>load</i> and any other arguments passed., and the values returned are those returned from <code>compile-file</code>.</p> <p>Otherwise, if <i>load</i> is true <code>compile-file-if-needed</code> loads the fasl file and returns <code>nil</code>, and if <i>load</i> is <code>nil</code> it simply returns <code>nil</code>.</p> |

Example

```
CL-USER 19 > (compile-file-if-needed "H:/tmp/foo.lisp"
   :output-file
   "C:/temp/")
;;; Compiling file H:/tmp/foo.lisp ...
;;; Safety = 3, Speed = 1, Space = 1, Float = 1,
Interruptible = 0
;;; Compilation speed = 1, Debug = 2, Fixnum safety = 3
;;; Source level debugging is off
;;; Source file recording is on
;;; Cross referencing is off
; (TOP-LEVEL-FORM 1)
; (TOP-LEVEL-FORM 2)
; (TOP-LEVEL-FORM 3)
; FOO
; BAR
#P"C:/temp/foo.ofasl"
NIL
NIL

CL-USER 20 > (compile-file-if-needed "H:/tmp/foo.lisp"
   :output-file
   "C:/temp/"
   :load t)
; Loading fasl file C:\temp\foo.ofasl
NIL
```

| Arguments   | <i>ccd</i>      | A <code>code-coverage-data</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <i>name</i>     | A Lisp object, normally a symbol or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | <i>pathname</i> | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <i>new-ccd</i>  | A <code>code-coverage-data</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |                 | <p>The function <code>copy-code-coverage-data</code> copies its <i>ccd</i> argument. The copy is deep, such that <i>ccd</i> and <i>new-ccd</i> do not share data, except read-only objects like pathnames. <i>name</i> is the name supplied to the new copy.</p> <p>The function <code>copy-current-code-coverage</code> copies the internal code coverage data. The default value of <i>name</i> is "Copy".</p> <p>The function <code>save-code-coverage-data</code> saves the code coverage data in <i>pathname</i>. The saving is done in the same binary form that the compiler and <code>dump-forms-to-file</code> use. The data can be loaded by <code>load-code-coverage-data</code>. <code>save-code-coverage-data</code> always saves to a file with type "ccd". If <i>pathname</i> does not have a type, <code>save-code-coverage-data</code> adds the type "ccd". If <i>pathname</i> has another type, <code>save-code-coverage-data</code> signals an error</p> <p>The function <code>save-current-code-coverage</code> saves the internal code coverage data. <i>name</i> is the name supplied to the saved data. The default value of <i>name</i> is (<i>pathname-name pathname</i>). Like <code>save-code-coverage-data</code>, <code>save-current-code-coverage</code> always saves to a file with type "ccd".</p> <p>The function <code>load-code-coverage-data</code> loads code coverage data from <i>pathname</i> and returns it. <i>pathname</i> must name a file that was created by <code>save-code-coverage-data</code> or <code>save-current-code-coverage</code> (with or without the "ccd" type).</p> |

*errorp* determines what to do when `load-code-coverage-data` fails to load. Value `nil` means return `nil`, otherwise it calls `error`. If *errorp* is true but not `t`, when `load-code-coverage-data` calls `error` it passes *errorp* as if it is the name of the function that fails. This can be used to give a better indication which function failed. The default value of *errorp* is `t`.

|          |                                                                                                                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | A <code>code-coverage-data</code> object can be also written "by hand" into fasl files using <code>dump-form</code> or <code>dump-forms-to-file</code> . In this case you will need to arrange to recover it when the fasl is loaded. <code>load-code-coverage-data</code> uses <code>load-data-file</code> with a <i>callback</i> . |

|             | <b>copy-to-weak-simple-vector</b> | <i>Function</i>                                                                                                                                                                                                           |
|-------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     |                                   | Creates a weak vector with the same contents as the supplied vector.                                                                                                                                                      |
| Package     |                                   | <code>hcl</code>                                                                                                                                                                                                          |
| Signature   |                                   | <code>copy-to-weak-simple-vector vector-t =&gt; weak-vector</code>                                                                                                                                                        |
| Arguments   | <code>vector-t</code>             | An array of type ( <code>vector t</code> ).                                                                                                                                                                               |
| Values      | <code>weak-vector</code>          | A weak array of type ( <code>vector t</code> ).                                                                                                                                                                           |
| Description |                                   | The function <code>copy-to-weak-simple-vector</code> creates and returns a weak vector with the same contents as the argument <code>vector-t</code> .<br><br>Apart from the checking of arguments, this is equivalent to: |

```
(replace (make-array (length vector-t)
                      :weak t)
        vector-t)
```

See **set-array-weak** for a description of weak vectors.

|             | <i>executable-name</i> | <code>t</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values      | <i>path</i>            | A pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description |                        | <p>The function <code>create-macos-application-bundle</code> creates a Mac OS X application bundle for the running LispWorks image, and returns the pathname <i>path</i> in which an image is expected to be saved. If you are saving an image, it is convenient to use <code>save-image-with-bundle</code>.</p> <p><i>target-path</i> is where the new bundle is created.</p> <p>By default <code>create-macos-application-bundle</code> uses the application bundle of the current image as a template, and modifies it according to its arguments. If you do not supply any of the keyword arguments, the only modification is to the actual path.</p> <p><i>template-bundle</i> can be supplied to provide a path for an application bundle which will be used as a template. If <i>template-bundle</i> is not supplied, <code>create-macos-application-bundle</code> uses the path of the bundle of the current image. Except when specified, all the other parameters default to their values in the <i>template-bundle</i>.</p> <p><i>bundle-name</i> provides <code>CFBundleName</code>. The default value is the name of the last directory component in <i>target-path</i>.</p> <p><i>signature</i> is the signature in the <code>PkgInfo</code> file.</p> <p><i>package-type</i> is the package type, <code>CFBundlePackageType</code>. The default value of <i>package-type</i> is "APPL".</p> <p><i>extension</i> is the extension to add to the last component of <i>target-path</i>. The default value of extension is "app", as in "Lisp-Works.app".</p> <p><i>application-icns</i> provides <code>CFBundleIconFile</code>.</p> <p><i>package-type</i> is the package type, <code>CFBundlePackageType</code>. The default value of <i>package-type</i> is "APPL".</p> |

*extension* is the extension to add to the last component of *target-path*. The default value of *extension* is "app", as in "Lisp-Works.app".

*application-icns* provides CFBundleIconFile.

*identifier* provides CFBundleIdentifier. You must change this if you are creating a bundle for your own application.

*version* is the version value, CFBundleVersion. If *template-bundle* is nil, *version* defaults to the value returned by `c1:lisp-implementation-version`.

*version-string* provides CFBundleShortVersionString. If *version-string* is `nil` (the default), then *version* and *build* (if non nil) are used to make a default string.

*help-book-folder* provides CFBundleHelpBookFolder.

*help-book-name* provides CFBundleHelpBookName.

*document-types* provides the CFBundleDocumentTypes dict array. Each item of the list *document-types* should be a list of the form (*name extensions icns-file os-types role*) which provide the dict values as follows: the string *name* provides CFBundleTypeName; the list of strings *extensions* provides the contents of the array CFBundleTypeExtensions; the pathname designator *icns-file* provides the string CFBundleTypeIconFile; the list of strings *os-types* provides the contents of the array CFBundleTypeOSTypes and the string *role* provides CFBundleTypeRole. *role* can be omitted and defaults to "Editor". *os-types* can be omitted and defaults to ("\*\*\*\*"). The default value of *document-types* is `t`, which means copy them from the application bundle *template-bundle*.

*executable-name* is the filename of the LispWorks image executable, not including the directory. The default value of *executable-name* is the pathname name of the last component of *target-path*.

#### Notes

`create-macos-application-bundle` is implemented only in LispWorks for Macintosh.

## **create-temp-file**

## **open-temp-file**

## *Functions*

Summary      Creates a "temp file" and returns a pathname or a stream to it.

Package      `hcl`

Signature      `create-temp-file &key file-type directory prefix => pathname`

Signature      `open-temp-file &key file-type element-type directory prefix  
delete-when-close external-format => stream`

Arguments      `file-type`      A string or `nil`.

`element-type`      A type specifier.

`directory`      A pathname designator.

`prefix`      A string or `nil`.

`delete-when-close`      A generalized boolean.

`external-format`      An external file format designator.

Values      `pathname`      A pathname.

`stream`      An I/O stream.

Description      The function `open-temp-file` opens a "temp file". This is a new file in the "temp directory" which is guaranteed to be new. Its name contains a random element. The permissions of the file are read-write for the user only.

`file-type` is the file type of the name. The default value of `file-type` is "tmp".

`directory`, if supplied, is the directory to create the file in. It defaults to the default temp directory, which is what `get-`

`temp-directory` returns, which defaults to what the Operating System uses as the temp directory.

`prefix` is used as the first part of the file name. The default prefix is "`lwtemp_machinename_pid`". More characters are appended to make the name unique and random.

If `delete-when-close` is non-nil, when the stream `stream` that is returned is closed, the system tries to delete the file quietly. That is, it tries to avoid giving an error if it fails.

`element-type` and `external-format` are interpreted the same way as in `open`.

The stream that is returned is an I/O stream.

The function `create-temp-file` creates a new temp file and returns the `pathname` for it. `create-temp-file` behaves exactly like `open-temp-file`, as described above, except that it returns a pathname rather than a stream to the new file.

Notes

1. `pathname` can be called to find the pathname that was used in `open-temp-file`. The file can be guaranteed to be new only if the temp directory is configured correctly.
2. The default "temp directory" can be found by using `get-temp-directory`.
3. When `delete-when-close` is non-nil, it tries to delete the file when the stream is closed, but that does not necessarily succeed. On Microsoft Windows it certainly fails when the file is still opened (for example, by another stream in the same process or another process)

| Signature          |                               | <code>create-universal-binary <i>target-image</i> <i>src-image1</i> <i>src-image2</i> =&gt; <i>target-image</i></code>                                                                                                                                                                                                                                                                                                  |
| Arguments          | <i>target-image</i>           | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                  |
|                    | <i>src-image1</i>             | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                  |
|                    | <i>src-image2</i>             | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values             | <i>target-image</i>           | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description        |                               | The function <code>create-universal-binary</code> is deprecated and signals an error.                                                                                                                                                                                                                                                                                                                                   |
| Compatibility note |                               | In LispWorks 6.1 for Macintosh and earlier versions, <code>create-universal-binary</code> creates a universal binary from two mono-architecture LispWorks images. It must be called only in a LispWorks for Macintosh image that is itself a universal binary.<br><br>In LispWorks 7.0 and later versions, universal binaries are not supported and hence <code>create-universal-binary</code> simply signals an error. |

| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature   | <code>current-function-name =&gt; name</code>                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments   | None                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <code>name</code> A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                               |
| Description | <p>The function <code>current-function-name</code> returns the name of the currently executing function as a string.</p> <p><code>name</code> is a string representing the name of the function from which <code>current-function-name</code> is called. The result is generated by <code>print-to-string</code> with the variable <code>*package*</code> bound to the <code>KEYWORD</code> package.</p>       |
| Notes       | <p><code>current-function-name</code> is for use in debugging, for example to give more context in a run time error message that is produced by a macroexpansion.</p> <p>The result when <code>current-function-name</code> is called outside a function (in a Listener or at the top level of a file) is not well defined. It is either <code>nil</code> or a name of some internally generated function.</p> |

| <b>current-stack-length</b> |                                                    | <i>Function</i> |
|-----------------------------|----------------------------------------------------|-----------------|
| Summary                     | Returns the size of the current stack.             |                 |
| Package                     | <code>hcl</code>                                   |                 |
| Signature                   | <code>current-stack-length =&gt; stack-size</code> |                 |
| Arguments                   | None                                               |                 |

|                     |                         |                                                                                                                                                                |
|---------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values              | <code>stack-size</code> | The current size of the stack, in 32 bit words (in 32-bit implementations) or 64-bit words (in 64-bit implementations).                                        |
| Compatibility notes |                         | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>current-stack-length</code> was not implemented. This is fixed in LispWorks 5.0 and later. |
| Example             |                         | <code>(current-stack-length) =&gt; 16000</code>                                                                                                                |

| Arguments   | <code>seconds</code>      | <code>nil</code> (default) or an integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <code>expand-month</code> | A generalized boolean, default false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Values      | <code>string</code>       | A string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description |                           | <p>The function <code>date-string</code> returns a string representing the date and time (including seconds).</p> <p>If <code>seconds</code> is <code>nil</code> (the default), <code>string</code> represents the current time. Otherwise, <code>seconds</code> is interpreted as a universal time and <code>string</code> represents that time.</p> <p>If <code>expand-month</code> is true then the date is written as DD MMM YYYY, with the month in characters. Otherwise, the date is written as YYYY/MM/DD, with the month in digits.</p> |

The time follows the date, separated by a space, and is always written as HH:MM:SS.

`date-string` is intended as a quick way of marking some text as related to some time. For example, the function `log-bug-form` starts by doing something like:

```
(format stream "==== Log at ~a ===~2%" (date-string))
```

| Description                                              | The function <code>declaration-information</code> returns information about the declarations for <i>decl-name</i> in the environment <i>env</i> .                                                                                                                                                              |                  |                    |            |                                    |
| The following values for <i>decl-name</i> are supported: |                                                                                                                                                                                                                                                                                                                |                  |                    |            |                                    |
| <code>optimize</code>                                    | The value of <i>info</i> is a list of lists of the form ( <i>quality value</i> ), where <i>quality</i> is one of the optimization qualities specified by the Common Lisp standard and LispWorks extensions ( <code>float</code> , for example). Each <i>value</i> is the corresponding value for that quality. |                  |                    |            |                                    |
| <code>declaration</code>                                 |                                                                                                                                                                                                                                                                                                                |                  |                    |            |                                    |

The value of *info* is a list of symbols that have been declared as declaration names, for example by use of  
`(declare (declaration ...))`

There are currently no other supported values for *decl-name*.

## **\*default-package-use-list\*** *Variable*

|               |                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | List of packages that newly created packages use by default.                                                                                                                      |
| Package       | <code>hcl</code>                                                                                                                                                                  |
| Initial value | <code>("CL" "LW" "HCL")</code>                                                                                                                                                    |
| Description   | This variable is the default value of the <code>:use</code> keyword to <code>defpackage</code> , which specifies which existing packages the package being defined inherits from. |

## **\*default-profiler-collapse\*** *Variable*

|         |                                          |
|---------|------------------------------------------|
| Summary | Controls collapsing of the profile tree. |
| Package | <code>hcl</code>                         |

|               |                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial value | <code>nil</code>                                                                                                                                                                                       |
| Description   | The variable <code>*default-profiler-collapse*</code> is a boolean indicating whether the profile tree should collapse functions with only one child function. The default value is <code>nil</code> . |
| See also      | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                        |

### **\*default-profiler-cutoff\*** *Variable*

|               |                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The minimum percentage that the profiler will display in the output tree.                                                                                                                                                                              |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                       |
| Initial value | <code>0</code>                                                                                                                                                                                                                                         |
| Description   | The variable <code>*default-profiler-cutoff*</code> is the minimum percentage (0 to 100) that the profiler will display in its output tree. Functions below this percentage will not be displayed. The initial value is 0, meaning display everything. |
| See also      | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                                                                        |

### **\*default-profiler-limit\*** *Variable*

|               |                                                                          |
|---------------|--------------------------------------------------------------------------|
| Summary       | The maximum number of lines of output that are printed during profiling. |
| Package       | <code>hcl</code>                                                         |
| Initial value | <code>100,000,000</code>                                                 |

|             |                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>*<code>default-profiler-limit</code>*</p> is the maximum number of lines of output in profile results. The default value is large to ensure that you receive all possible output requested.                                                                                                                                       |
|             | <p>*<code>default-profiler-limit</code>*</p> only counts output lines for functions that are actually called during profiling. Therefore, if * <code>default-profiler-limit</code> * is 19, and 20 functions were profiled, you would receive full output if one or more of the functions were not actually called during profiling. |
| See also    | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                                                                                                                                                      |

## **\*default-profiler-sort\*** *Variable*

|               |                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The default sorting style for the profiler.                                                                                                                                                                                    |
| Package       | <code>hcl</code>                                                                                                                                                                                                               |
| Initial value | <code>:profile</code>                                                                                                                                                                                                          |
| Description   | The variable * <code>default-profiler-limit</code> * controls which column of the profiler's columnar report is used for sorting.<br>The value can be one of <code>:profile</code> , <code>:call</code> or <code>:top</code> . |
| See also      | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                                                |

## **defglobal-parameter** *Function*

|           |                                                                                  |
|-----------|----------------------------------------------------------------------------------|
| Summary   | Defines a <code>hcl:special-global</code> parameter.                             |
| Package   | <code>hcl</code>                                                                 |
| Signature | <code>defglobal-parameter name initial-value &amp;optional doc =&gt; name</code> |

|             |                                                                                                                                                                                    |                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Arguments   | <i>name</i>                                                                                                                                                                        | A symbol.      |
|             | <i>initial-value</i>                                                                                                                                                               | A Lisp object. |
|             | <i>doc</i>                                                                                                                                                                         | A string.      |
| Values      | <i>name</i>                                                                                                                                                                        | A symbol.      |
| Description | The macro <code>defglobal-parameter</code> has the same semantics as <code>cl:defparameter</code> , but also declares the name <i>name</i> to be <code>hcl:special-global</code> . |                |
| See also    | <code>defglobal-variable</code>                                                                                                                                                    |                |

| <b>defglobal-variable</b> |                                                                                                                                                                             | <i>Function</i> |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                   | Defines a <code>hcl:special-global</code> variable.                                                                                                                         |                 |

| Values      | <code>decl-name</code>                                                                                                                                                                                                                                                                                                                          | A symbol.              |
| Description | The macro <code>define-declaration</code> defines a handler for <code>decl-name</code> , which tells the compiler and <code>augment-environment</code> how to deal with this declaration. The handler is a function with lambda list <code>lambda-list</code> , and body <code>body</code> , that is the same function as would be produced by: |                        |

```
#'(lambda lambda-list . body)
```

When the compiler and `augment-environment` processes a declaration with `decl-name` as the first element, the handler is called with two arguments:

- The declaration itself.
- The environment, which is the compilation environment in the compiler and the new environment in `augment-environment`.

The handler must return two values. The first value specifies what kind of declaration it is, and must be one of:

`:variable`      The declaration applies to variable bindings, and hence affects the result of `variable-information`.

|                        |                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>:function</code> | The declaration applies to function bindings, and hence affects the result of <code>function-information</code> . |
| <code>:declare</code>  | The declaration does not apply to bindings, and affects the result of <code>declaration-information</code> .      |

If the first value is `:variable` or `:function` then the second value must be a list, the elements of which are lists of the form (*binding-name key value*). If the corresponding information function (either `variable-information` or `function-information`) is called with *binding-name* and the environment, then the a-list returned by the information function as its third value will have *value* associated with *key*.

If the first value is `:declare`, then the second value must be a cons of the form (*key . value*). The function `declaration-information` will return *value* when called with *key* and the environment.

`define-declaration` causes *decl-name* to be proclaimed as a declaration, as if by:

```
(proclaim '(declaration decl-name))
```

*decl-name* must not be a standard declaration identifier; `define-declaration` signals an error if it is.

The consequences are undefined if a *key* returned by a declaration handler defined with `define-declaration` is a symbol that is used by the corresponding information function to return information about any standard declaration specifier. For example, if the first return value from the handler is `:variable`, then the second return value should not use the symbols `dynamic-extent`, `ignore`, or `type` as *key*, because they are reserved by `variable-information` to return information about the corresponding standard declaration.

#### Notes

Using a declaration defined by `define-declaration` affects only the return values of `variable-information`, `func-`

`tion-information` OR `declaration-information` as described above. It does not affect the behavior of the compiler. `define-declaration` is intended for use by code walkers that require extra information in the environment.

The evaluator ignores declarations defined by `define-declaration`.

`define-declaration` does not have any compile-time effect so must have been evaluated before a declaration for `decl-name` is processed.

`augment-environment` processes declarations last, so the environment that is passed to the handler already contains any other information that was passed to `augment-environment`.

The implementation of `define-declaration` is based on the specification in Common Lisp the Language, 2nd Edition as on CMU website on 10 Feb 2016:  
<http://www.cs.cmu.edu/Groups/AI/html/cltl/clm/node102.html>.

See “Function dspecs” on page 84 for description of function-dspec.                                       |
|             | <i>name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A symbol naming the piece of advice to be removed. Since several pieces of advice may be attached to a single functional definition, the name is necessary to indicate which one is to be removed. |
| Values      | <code>delete-advice</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                    |
| Description | <p><code>delete-advice</code> is used to remove a piece of advice. Advice is a way of altering the behavior of functions. Pieces of advice are associated with a function using <code>defadvice</code>. They define additional actions to be performed when the function is invoked, or alternative code to be performed instead of the function, which may or may not access the original definition. As well as being attached to ordinary functions, advice may be attached to methods and to macros (in this case it is in fact associated with the macro’s expansion function).</p> <p><code>remove-advice</code> is a function, identical in effect to <code>delete-advice</code>, except that you need to quote the arguments.</p> |                                                                                                                                                                                                    |
| Notes       | <code>delete-advice</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                    |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>deliver-to-android-project</code> delivers a LispWorks runtime for the Android platform.</p> <p><code>deliver-to-android-project</code> creates two files, a Lisp heap and a dynamic library, that needs to be part of an Android project to be used on Android. It does some Android-specific processing, and then calls <code>deliver</code>.</p> <p>If <i>function</i> is non-nil it is the restart function which is called after the LispWorks runtime finishes initializing. It is called on another process (by <code>funcall-async</code>), and its return value is not used. By the time the function <i>function</i> is called, LispWorks is ready to receive calls from Java, and a call from <i>function</i> to Java may be used to inform Java that LispWorks is ready instead of the <i>reporter</i> argument to <code>com.lispworks.Manager.init</code> (or in parallel to it). The function <i>function</i> should return in short time, If you want it to linger, use <code>process-run-function</code> to start another with a function that lingers, and return from <i>function</i>.</p> <p><i>project-path</i> is the path of the Android project, except when <i>no-sub-dir</i> is supplied, when it defines a directory to put the files. When delivering into an Android Studio project, <i>project-path</i> can be either the root of the project or the "main" directory (the location of the file <code>AndroidManifest.xml</code>).</p> <p><i>level</i> is the delivery level. It is passed to <code>deliver</code>. See the documentation for <code>deliver</code> for details.</p> <p><i>library-name</i> when supplied must be a string, and defines the base name of the files. The call to <code>com.lispworks.Manager.init</code> which initializes LispWorks must match <i>library-name</i>. The default value of <i>library-name</i> is "LispWorks".</p> <p><b>Note:</b> Actually the call <code>com.lispworks.Manager.init</code> uses the name to find the files, so if you rename the files <code>com.lispworks.Manager.init</code> must match the names of the files, rather than <i>library-name</i>.</p> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*using-ndk* needs to be true if the Android project is built using Eclipse and uses NDK to build C code. The default value of *using-ndk* is `nil`.

*no-sub-dir*, when non-`nil`, tells `deliver-to-android-project` that the *project-path* argument is the directory where the files need to go, rather than a project path. In this case `deliver-to-android-project` does not look for sub-directories. If *no-sub-dir* is a pathname or string, it specifies a directory where the heap should go. If this directory is relative, it is relative to the *project-path* directory. If *no-sub-dir* is `t`, it specifies that the heap should go at top level in *project-path*. When *no-sub-dir* is passed, it is your responsibility to ensure that the files end up in the right place in the Android project. *no-sub-dir* is useful when the delivery cannot be done directly into the Android Project, for example when it is on a different machine or there are permissions issues. It may also be useful if you have a project with a directory structure that does not match the structure that `deliver-to-android-project` expects. The default value of *no-sub-dir* is `nil`.

*studio-p* tells `deliver-to-android-project` whether the target Android project is built with Android Studio or not, which is used to decide where the files go. When *studio-p* is not passed, `deliver-to-android-project` tries to determine whether it is Android Studio as described below.

`deliver-to-android-project` first decides the names of the files to generate and where they should go.

The two files that `deliver-to-android-project` generates are named `lib<library-name>.so.lwheap` for the heap file, and `lib<library-name>.so` for the dynamic library, so by default the names are `libLispWorks.so.lwheap` and `libLispWorks.so`.

The directory or directories where the files go are determined as follows:

1. When *no-sub-dir* is `nil` (the default), it first checks whether the *project-path* contains a file named `AndroidManifest.xml`.
  - a) If the file `AndroidManifest.xml` exists, then this is the "main" path. If *studio-p* was not supplied, it sets *studio-p* to `t` if there is a directory called "java" in the "main" directory, otherwise it sets *studio-p* to `nil`.
  - b) If there is no `AndroidManifest.xml` file, it checks whether inside the *project-path* there is a sub-sub-sub-directory `app/src/main`, and whether `AndroidManifest.xml` exists in it. If so, it takes the sub-sub-sub-directory as the "Main" directory, and sets *studio-p* to `t` (ignoring any supplied value).

Once it decided where the "Main" directory is, it puts the heap in its "assets" sub-directory, and the dynamic library in its "jni libs" sub-directory. The "jni libs" directory is:

- (i) If *studio-p* is `t` it is "`jniLibs/armeabi-v7a`".
  - (ii) Otherwise if *using-ndk* is `nil` it is "`libs/armeabi-v7a`".
  - (iii) Otherwise it is "`jni`".
2. If *no-sub-dir* is non-nil, then the dynamic library is put in the *project-path* directory. If *no-sub-dir* is `t`, the heap is put in the same place. Otherwise, the directory specified by *no-sub-dir* is merged with the *project-path* to create the path where the heap goes.

Note: If *no-sub-dir* is a pathname or string it must specify a directory, which can be an absolute path.

After `deliver-to-android-project` determines the names of the files and where they go, it calls `deliver`, passing *function*, the appropriate path, *level*, the Delivery keywords `:split`, `:exe-file`, `:dll-exports` and `:image-type` with the correct values for Android, and all the keyword arguments it was supplied except *library-name*, *using-ndk*, *studio-p* and *no-sub-dir*. The keywords that `deliver-to-android-`

`project` passes explicitly should not be used, but the rest of the Deliver keywords can be used and are interpreted in the standard way (see the *LispWorks Delivery User Guide* for details). However, since CAPI is not available on Android, all keywords related to CAPI are not useful.

## Notes

1. With Android Studio you do not need `using-ndk`. You need it when you use `ndk-build` to build dynamic libraries in your project. In Eclipse that is normally done by the CDT builder. You need `using-ndk` because the `ndk-build` removes all dynamic libraries from the `libs` sub-directory and its sub-directories, including the LispWorks dynamic library. The solution for this is to pass a true value for `using-ndk` to `deliver-to-android-project`, and add to the `Android.mk` file in the `jni` sub-directory the lines that are required to copy the LispWorks dynamic library to `libs/armeabi-v7a`. Assuming you do not pass `library-name`, these lines in `Android.mk` should be:

```
LOCAL_SRC_FILES := libLispWorks.so  
LOCAL_MODULE      := LispWorks  
include $(PREBUILT_SHARED_LIBRARY)
```

If you pass `library-name`, you need to change the lines above to match your change. There can be other solutions, for example you can deliver elsewhere, and add a build step that copies the LispWorks files into the project after the CDT builder (on Eclipse). If the build in Eclipse is changed not to delete files from the `libs` directory, then `using-ndk` is not needed.

2. Like `deliver`, `deliver-to-android-project` cannot be called with multiprocessing running, and is best called inside a script that is passed to LispWorks by the command line argument `-build`.

3. `deliver-to-android-project` is available only in the Android delivery image `lispworks-7-1-0-arm-linux-android`. This image is an ARM image, and must be run on ARM architecture. That can be either an ARM machine, or an ARM emulator.

To deliver a LispWorks for Android Runtime image with a delivery script that calls `deliver-to-android-project` using the QEMU emulator, use the shell script `examples/android/run-lw-android.sh`, which passes its arguments to `lispworks-7-1-0-arm-linux-android`:

```
run-lw-android.sh -build /path/to/delivery-script.lisp
```

4. The algorithm for finding the directories will work for Eclipse and for Android Studio with the default settings. Android Studio is very flexible and still in flux, so may change. It seems unlikely that the names of the sub-directories (`assets`, `jnilibs` and `java`) will change, but the main directory may move around. Supplying the actual main directory rather than the root should still work. If this does not work, you can supply `no-sub-dir` to either put the files in the right directories, or just put it in some directory and copy it to the right place.

### **\*disable-trace\***

### **Variable**

Summary      Controls tracing.

Package      `hcl`

Initial value      `nil`

|             |                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <code>*disable-trace*</code> controls tracing without affecting the tracing state. If it is set to <code>t</code> then tracing is switched off, but this does not call <code>untrace</code> . When the value of <code>*disable-trace*</code> is restored to <code>nil</code> , tracing continues as before. |
| Notes       | <code>*disable-trace*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                |
| See also    | <code>trace</code>                                                                                                                                                                                                                                                                                          |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <i>Function</i> |

| Arguments           | <p><i>initialize</i>      A boolean.</p> <p><i>processes</i>     One of <code>:current</code>, <code>:all</code>, a <code>mp:process</code> or a list of <code>mp:process</code> objects.</p> <p><i>profile-waiting</i>    A boolean.</p> <p><i>ignore-in-foreign</i>   A boolean.</p> <p><i>sleep</i>            A non-negative number, or <code>nil</code>.</p> <p><i>function</i>        A function designator.</p> <p><i>arguments</i>      Arguments passed to <i>function</i>.</p> <p><i>func-and-args</i>    A function designator or a list (<i>function-designator</i> . <i>args</i>).</p> <p><i>print</i>            A generalized boolean.</p> <p><i>stream</i>          An output stream.</p> |                 |

Description      The function **do-profiling** is a convenience function for profiling multiple threads, combining **start-profiling** and **stop-profiling**.

The behavior of **do-profiling** with no arguments is the same as:

```
(progn
  (start-profiling :processes :all)
  (sleep 6)
  (stop-profiling))
```

The arguments *initialize*, *processes*, *profile-waiting* and *ignore-in-foreign* are passed to **start-profiling**. They have the same default values as for **start-profiling**, except *processes* which defaults to **:all**.

The arguments *print* and *stream* are passed to **stop-profiling**. They have the same default values as in **stop-profiling**.

*sleep* is the time to sleep in seconds. If *sleep* is **nil** or 0 **do-profiling** does not sleep. Also, if *sleep* is supplied and either *function* or *func-and-args* are passed, it does not sleep.

*func-and-args*, and *function* together with *arguments*, can both be used for calling a function you supply. *func-and-args* is either a list of the form **(function-designator . args)**, in which case *function-designator* is applied to the *args*, or it is a function designator which is called without arguments. *function* is applied to *arguments*.

The order of execution is first *func-and-args* (if this is non-nil), then *function* together with *arguments* if *function* is non-nil, and then sleep if *sleep* was passed explicitly or both *function* and *func-and-args* are **nil**.

Example      To profile whatever happens in the next 6 seconds:

```
(hcl:do-profiling)
```

To profile whatever happens in the next 10 minutes:

```
(hcl:do-profiling :sleep 600)
```

To run 4 processes in parallel with the same function and profile until they all die:

```
(defun check-all-processes-died (processes)
  (dolist (p processes t)
    (when (mp:process-alive-p p)
      (return nil)))

  (let ((processes
         (loop for x below 4
               collect
               (mp:process-run-function
                 (format nil "my process ~a" x)
                 () 'my-function))))
    (hcl:do-profiling
      :func-and-args
      (list 'mp:process-wait
            "Waiting for processes to finish"
            'check-all-process-died
            processes)))
```

## editor-color-code-coverage

*Function*

Summary      Displays code coverage in an Editor tool for one file.

Package      `hcl`

Signature      `editor-color-code-coverage filename &key code-coverage-data  
for-editing show-counters color-covered color-uncovered => result`

Arguments      `filename`      A pathname designator.

`code-coverage-data`  
                A `code-coverage-data` object.

`for-editing`      A boolean.

|             |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Values      | <i>result</i>           | An editor buffer object, or a list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |                         | <p>The function <code>editor-color-code-coverage</code> displays code coverage in an Editor tool in the LispWorks IDE for one file. <i>filename</i> must specify a source file, which has code coverage information in the <i>code-coverage-data</i>.</p> <p>If <i>code-coverage-data</i> is not supplied, it defaults to the internal code coverage data, that is its binary file with code coverage data was loaded in the current image or <code>restore-code-coverage-data</code> was called with data that contains this file. Otherwise, it must specify a <code>code-coverage-data</code> object with data for this file.</p> <p><i>for-editing</i> specifies whether is intended that the buffer with the coloring will be editable. When <i>for-editing</i> is <code>nil</code>, a buffer without a pathname is created with a different name from the source file, which prevents accidental overwriting of the source file. If <i>for-editing</i> is non-<code>nil</code>, the file is opened in the normal way, which may mean using an existing editor buffer if it is already opened. Unless you supply <i>show-counters</i>, a buffer that is opened with <i>for-editing</i> non-<code>nil</code> does not contain any modification of the source code. The default value of <i>editing</i> is <code>nil</code>.</p> <p>Depending on the value of <i>comment-counters</i>, the counters may be wrapped by <code>#     #</code>. When <i>show-counters</i> is non-<code>nil</code>,</p> |

counters are inserted inside the source code. The counters are wrapped in #| |#, so the code is still functional, but less readable. The default value of *show-counters* is (not *for-editing*).

*color-covered* and *color-uncovered* control whether to color covered and uncovered forms respectively. The default value of *color-covered* is `nil`. The default value of *color-uncovered* is `t`. The default for *color-covered* and *color-uncovered* can be set in the LispWorks IDE **Preferences...** dialog for Code Coverage Browser, tab **Coloring**.

*font-lock-p* controls whether font lock (that is, color according to Lisp syntax in the normal way) should be done. When it is `t`, if the buffer is not already "font locked", it is "font locked" before coloring for code coverage. If *font-lock-p* is `:force`, the buffer is always "font locked" first.

*comment-counters* controls whether to comment counters when they are added. It has no effect when *show-counters* is `nil`. When the counters are commented, the code is still valid, because the reader just skips the counters, so you can edit and compile it. When the counters are not commented, the code is not valid, but it is easier to read. The default for *comment-counters* can be set in the **Preferences...** dialog for Code Coverage Browser, tab **Coloring**. The initial default value of *comment-counters* is `t`.

*runtime-only* controls whether to display only run time forms, which means exclude forms that execute only at compile time or load time. The default for *runtime-only* can be set in the **Preferences...** dialog for Code Coverage Browser, tab **Coloring**. The initial default value of *runtime-only* is `nil`.

*real-filename* may be used to specify the actual file to load. When it is non-nil, *filename* should be a pathname which is the same as the truename that the compiler used when it compiled the file to generate the code coverage. The filename is used to lookup the data in the *code-coverage-data* object, while *real-filename* is used as the actual text to load. Note that while *filename* needs to be the same as the truename that the

compiler used, it is not necessarily a real truename on the current machine.

`editor-color-code-coverage` returns the editor buffer if it is successful. If it fails it returns a list containing a format string followed by format arguments, which can be used to present an error or message to the user.

If `editor-color-code-coverage` succeeds and *for-editing* is `nil`, it remembers that it generated the buffer for the *filename*, and if it is called again with the same *filename* and *for-editing* `nil` and succeeds, deletes the previous buffer.

See “Understanding the code coverage output” on page 124 for details of how to interpret the coloring.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <i>real-filename</i> is used when the coloring is done on a machine which sees the file via a different pathname than the machine that compiled it, or when the code coverage data is generated from a copy of the source. The mapping in the Code Coverage browser uses it. Figuring out the truename on a different machine is not always easy. The best way is way is to use the one from the data, which you can find either by searching the data using <code>map-code-coverage-data</code> , or from a <code>code-coverage-file-stats</code> object if you already have it. |

|             | <i>size</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | The amount (in bytes) by which the generation is to be enlarged. |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | A boolean.                                                       |
| Description | <p>The function <code>enlarge-generation</code> enlarges generation <i>gen-num</i> by <i>size</i> bytes. If possible, an existing segment in generation <i>gen-num</i> is enlarged, otherwise a new segment of size <i>size</i> is added to the generation.</p> <p><i>result</i> is <code>t</code> on success and <code>nil</code> on failure.</p> <p>This function is useful when it is known that a generation will need to grow. After <code>enlarge-generation</code> is called, the garbage collector is saved the work of deducing that the generation must grow.</p> <p><code>enlarge-generation</code> is most useful in non-interactive applications, where relatively long GC delays are not a problem. In this case, enlarging generations 0 and 1 by several MB may improve the overall performance of the GC.</p> |                                                                  |
| Notes       | <p><code>enlarge-generation</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations. In 64-bit implementations you can use <code>set-default-segment-size</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                  |
| See also    | <p><code>set-default-segment-size</code><br/> “Memory Management in 32-bit LispWorks” on page 135</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                  |

## enlarge-static *Function*

|         |                                                                    |
|---------|--------------------------------------------------------------------|
| Summary | Enlarges the size of the first static segment in 32-bit LispWorks. |
| Package | <code>hcl</code>                                                   |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                      |

| Description | <p>This function can be used when the system would otherwise allocate additional static segments. Such additional segments would cause the application to grow irreversibly.</p> <p><code>size</code> is the amount (in bytes) by which the static segment is to be enlarged. It is rounded up to a multiple of 64K.</p> <p><code>result</code> is <code>t</code> if the static segment was successfully enlarged, and <code>nil</code> otherwise.</p> <p>Use <code>room</code>, with argument <code>t</code>, to find the size of the static segments, and thus the size by which to enlarge the first static segment.</p> |                                      |
| Notes       | <p><code>enlarge-static</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where the irreversible growth problem described above does not exist.</p>                                                                                                                                                                                                                                                                                                                                                                                                |                                      |

|             | <code>new-value</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | A Lisp object.                                        |
|             | <code>in-lock-constructor</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A function designator for a function of one argument. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A Lisp object.                                        |
| Description | <p>The function <code>ensure-hash-entry</code> gets the value for the key <code>key</code> in the hash table <code>hash-table</code>, and if this fails puts a new value <code>new-value</code> in <code>hash-table</code> and returns it. <code>ensure-hash-entry</code> does all this with <code>hash-table</code> locked.</p> <p>If the key <code>key</code> is not found, then if <code>in-lock-constructor</code> is non-nil then <code>in-lock-constructor</code> is called with <code>new-value</code> as its argument, and the result is put in the table and returned. If <code>key</code> is not found and <code>in-lock-constructor</code> is <code>nil</code>, <code>new-value</code> is put in the table and returned.</p> |                                                       |
| Notes       | <p><code>ensure-hash-entry</code> is quite inefficient because it always locks the hash table. Normally you should use <code>with-ensuring-gethash</code> or <code>gethash-ensuring</code> instead.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                       |

| Arguments   | <code>body</code> Lisp forms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | <code>result</code> The result of evaluating <code>body</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description | <p>The macro <code>error-situation-forms</code> tells the compiler that a body of code comprises "error situation" forms.</p> <p><code>body</code> is evaluated as an implicit progn, but its forms are treated as "error situation" forms. Currently that means that the compiler does not generate code coverage inside <code>body</code> or for the <code>(error-situation-forms ...)</code> form itself, unless <code>force</code> was supplied non-nil to <code>generate-code-coverage</code> or <code>with-code-coverage-generation</code>.</p> <p>In the future, it may also affect other parameters.</p> |
| Notes       | For code coverage, <code>error-situation-forms</code> differs from <code>without-code-coverage</code> in that it does not generate a counter for the <code>(error-situation-forms ...)</code> form itself, and therefore is more convenient to use.                                                                                                                                                                                                                                                                                                                                                              |
| Examples    | <pre>(if (check-something)     (ok-code)     (error-situation-forms (call-error)))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Signature   | <code>expand-generation-1 <i>on</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Arguments   | <code><i>on</i></code> <code>t, nil</code> or <code>1</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | <p>The function <code>expand-generation-1</code> controls the subsequent behavior of the garbage collector when insufficient space is freed by a <code>mark-and-sweep</code>. When this occurs, either generation 1 is expanded, or the objects in it are promoted.</p> <p>If <code>on</code> is <code>nil</code>, generation 1 is never expanded.</p> <p>If <code>on</code> is <code>t</code>, generation 1 is always expanded (rather than promotion) when needed.</p> <p>If <code>on</code> is <code>1</code>, generation 1 is only expanded if its current size is less than 500000 bytes. This is the initial setting.</p> |
| Notes       | <code>expand-generation-1</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where you can use <code>set-default-segment-size</code> .                                                                                                                                                                                                                                                                                                                                                                                                                  |

|           | <i>Function</i>                                                                   |
|-----------|-----------------------------------------------------------------------------------|
| Summary   | Extends the current stack.                                                        |
| Package   | <code>hcl</code>                                                                  |
| Signature | <code>extend-current-stack &amp;optional <i>how-much</i> =&gt; <i>size</i></code> |

|                     |                                                                                                                                                               |                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Arguments           | <i>how-much</i>                                                                                                                                               | What percentage the stack should be extended by. The default is 50. |
| Values              | <i>size</i>                                                                                                                                                   | The new size of the stack, after extending.                         |
| Description         | Extend the current stack by the given percentage.                                                                                                             |                                                                     |
| Compatibility notes | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>extend-current-stack</code> is not implemented. This is fixed in LispWorks 5.0 and later. |                                                                     |
| Example             | To double the size of the current stack:                                                                                                                      |                                                                     |
|                     |                                                                                                                                                               | <code>(hcl:extend-current-stack 100)</code>                         |
| See also            | <code>current-stack-length</code><br><code>*stack-overflow-behaviour*</code>                                                                                  |                                                                     |

## **extended-time** *Macro*

|             |                                                                                                                                                                                                                                                                                                                                                             |                        |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | Prints useful timing information, including information on garbage collection (GC) activity.                                                                                                                                                                                                                                                                |                        |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                            |                        |
| Signature   | <code>extended-time &amp;body body</code>                                                                                                                                                                                                                                                                                                                   |                        |
| Arguments   | <i>body</i>                                                                                                                                                                                                                                                                                                                                                 | The forms to be timed. |
| Description | <p>The macro <code>extended-time</code> runs the forms in <i>body</i>. It then prints a summary of the time taken followed by a breakdown of time spent in the GC.</p> <p>The three columns of the GC breakdown show, respectively, total time, user time, and system time, all in seconds. The rows of the GC breakdown indicate the type of activity.</p> |                        |
|             | In 32-bit LispWorks these rows begin:                                                                                                                                                                                                                                                                                                                       |                        |

**main promote**

indicates promotions from generation 0.

**internal promote**

indicates when an attempt to promote from one generation to the next causes promotion of the higher generation, to make room for the objects from the lower generation.

**fixup**

is a part of the compaction and promotion process.

In 64-bit LispWorks these rows begin:

**Standard *gen-num* (*n* calls)**

indicates *n* Standard GCs (includes automatic GCs and calls to `gc-generation`) in which the highest generation collected was *gen-num*.

**Marking *gen-num* (*n* calls)**

indicates *n* Marking GCs (includes calls to `marking-gc`) in which the highest generation collected was *gen-num*.

Thus in the example below

**Standard 1 ( 1 calls) ...**

indicates that there was 1 Standard GC in which the highest generation collected was 1.

Notes

`extended-time` does not print Garbage Collector times if it is used while GC timing is on (after `start-gc-timing` is called, and before `get-gc-timing` is called with `reset` non-nil).

Example

This example illustrates output in 32-bit LispWorks:

```
CL-USER 57 > (extended-time (foo))
Timing the evaluation of (PROGN (FOO))

User time      =      26.703
System time   =       0.109
Elapsed time  =      27.047
Allocation    = 40021902832 bytes
0 Page faults

   total / user
/ system
total gc activity                  = 3.312500 /
3.312500 / 0.000000
main promote ( 1 calls)          = 0.000000 /
0.000000 / 0.000000
mark and sweep ( 7305 calls)     = 3.312500 /
3.312500 / 0.000000
internal promote ( 0 calls)     = 0.000000 /
0.000000 / 0.000000
promote ( 0 calls)               = 0.000000 /
0.000000 / 0.000000
fixup ( 1 calls)                 = 0.000000 /
0.000000 / 0.000000
compact ( 0 calls)               = 0.000000 /
0.000000 / 0.000000
10006387712
0.0
```

This example illustrates output in 64-bit LispWorks:

```

CL-USER 3 > (extended-time (foo))
Timing the evaluation of (PROGN (FOO))

User time      =      11.433
System time    =       0.268
Elapsed time   =      11.197
Allocation     = 80040251696 bytes
5 Page faults

   total / user /
system
total gc activity                  =      2.168062 / 2.126444
/ 0.041618
Standard 0 (28545 calls) =      2.153886 / 2.119799
/ 0.034087
Standard 1 (    1 calls) =      0.014176 / 0.006645
/ 0.007531
10006387712
0.0

```

| <b>fdf-handle-writable-p</b>       | <i>Functions</i> |

**Summary**      Maps a callback on the names of files in a specified directory and returns a list of those for which the callback returned true. The callback can retrieve information about the files.

**Package**      `hcl`

**Signature**      `fast-directory-files dir-pathname callback => result`  
`fdf-handle-directory-p fdf-handle => directory-p`  
`fdf-handle-directory-string fdf-handle => directory-string`  
`fdf-handle-last-access fdf-handle => last-access`  
`fdf-handle-last-modify fdf-handle => last-modify`  
`fdf-handle-link-p fdf-handle => link-p`  
`fdf-handle-size fdf-handle => size`  
`fdf-handle-writable-p fdf-handle => writable-p`

**Arguments**      `dir-pathname`      A pathname designator without wild characters in its directory path.  
`callback`          A function designator.  
`fdf-handle`        An opaque object used to retrieve information about a file in `dir-pathname`.

**Values**      `result`          A list of strings.  
`directory-p, link-p, writable-p`

Booleans.

*directory-string* A string.

*last-access, last-modify, size*

Integers.

Description The function **fast-directory-files** maps the function *callback* on the names of the files in directory specified by *dir-pathname*, and returns a list of the names for which *callback* returned non-nil.

*dir-pathname* must be a pathname designator, which does not contain wild characters in its directory path. To be useful, it should either be a directory (with no name and type), or with wild name and/or type.

*callback* must be a function of two arguments, the name of the file and an opaque object which is referred to as the *fdf-handle*. The *fdf-handle* can be used to retrieve information about the file, by calling any of the **fdf-handle-\*** functions documented on this page.

**fast-directory-files** traverses the files that match *dir-pathname* in an undefined way, and for each file calls the *callback* with the file's name (not including the directory) and a *fdf-handle*. If *callback* returns non-nil it adds the name to a list. It returns the list of names for which the *callback* returned non-nil. Note that the names do not contain the directory name.

The *fdf-handle* can be accessed by the following readers. Functions named in parentheses would return the same value when called on the full path of the file:

**fdf-handle-size** returns the size of the file in bytes.

**fdf-handle-last-modify** returns the universal time of the last modification of the file (**cl:file-write-date**).

**fdf-handle-last-access** returns the universal time of the last access of the file.

**fdf-handle-directory-p** is a predicate for whether the file is a directory (**file-directory-p**)

**fdf-handle-link-p** is a predicate for whether the file is a soft link (always returns `nil` on Windows).

`fdf-handle-writable-p` is a predicate for whether the file is writable (`file-writable-p`).

**fdf-handle-directory-string** returns a string with the directory path followed by a separator. Therefore the full path of the file can be constructed by:

```
(string-append (fdf-handle-directory-string fdf-handle)  
               name)
```

|          |                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------|
| Notes    | The <code>fdf-handle</code> can be used only within the dynamic scope of the callback to which it was passed. |

| Arguments   | <code>file</code>                                                                                                                                                                                                                                                                            | A pathname, string or file-stream, designating a file. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                          | <code>t</code> or <code>nil</code>                     |
| Description | The function <code>file-writable-p</code> checks whether <i>file</i> is writable. Note that this checks the properties of the file, so trying to write to the file may still fail if the file is non-writable for other reasons, for example if it is opened for writing by another program. |                                                        |
| Example     | <pre>CL-USER 44 &gt; file-writable-p (sys:lispworks-file "private-patches/load.lisp") T</pre>                                                                                                                                                                                                |                                                        |

| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A <code>code-coverage-data</code> object.                    |
| Description | <p>The function <code>filter-code-coverage-data</code> creates a new <code>code-coverage-data</code> object with information for some of the files in the argument <code>ccd</code>, as determined by the <code>filter</code>. If <code>ccd</code> is <code>t</code>, this is interpreted as the internal <code>code-coverage-data</code> object.</p> <p>If <code>filter</code> is a string, it is interpreted as a regexp (see <code>find-regexp-in-string</code>) which is applied to the namestring of each file. <code>without-stats</code> is ignored in this case.</p> <p>If <code>filter</code> is a function or a fbound symbol, it is applied to the truename of each file and stats object or only to the truename, depending on <code>without-stats</code>. If <code>without-stats</code> is <code>nil</code> the <code>filter</code> is applied to the truename and a <code>code-coverage-file-stats</code> object for the file. If <code>without-stats</code> is true, the <code>filter</code> is applied only to the truename. The default value of <code>without-stats</code> is <code>nil</code>.</p> <p><code>name</code> is the name supplied to the new <code>code-coverage-data</code> object. The default value of <code>name</code> is "Filter".</p> |                                                              |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the size in bytes of the representation of any Lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Signature   | <code>find-object-size <i>object</i> =&gt; <i>size</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Arguments   | <i>object</i> Any Common Lisp form.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values      | <p>The result is an integer which is the number of bytes of heap memory currently used to represent the object. If the object takes up no heap memory (fixnum or character), then 0 is returned. Such objects are represented by an immediate value held in a single machine “word”.</p> <p>The size of a heap object includes hidden space required to hold type and other information; for instance, a base-string of 10 1-byte characters occupies more than 10 bytes of memory.</p> |
| Description | Certain Common Lisp objects are not represented by a single heap object; for instance, using <code>find-object-size</code> on a hash-table is misleading as the function returns the size of the hash-table descriptor, rather than the total of the descriptor and the hash-table-array. General vectors and arrays also have this property. All symbols are of the same size, since the print name is not part of a symbol object.                                                    |
| Example     | <pre>(hcl:find-object-size   (make-string 1000 :initial-element #\A                :element-type 'base-char)) =&gt; 1012</pre>                                                                                                                                                                                                                                                                                                                                                          |

## **find-throw-tag** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| Summary     | The predicate for whether there is a specific catch in the dynamic scope.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |              |
| Package     | <b>hcl</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |
| Signature   | <b>find-throw-tag</b> <i>tag</i> => <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |              |
| Arguments   | <i>tag</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A catch tag. |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | A boolean.   |
| Description | The function <b>find-throw-tag</b> is the predicate for whether there is a catch in the dynamic scope with the supplied catch tag <i>tag</i> , so that <b>c1:throw</b> will succeed to throw to it.                                                                                                                                                                                                                                                                                                                             |              |
| Notes       | <b>find-throw-tag</b> needs to traverse all the catch frames on the stack until it finds the tag, and therefore would be slower than checking a dynamically bound variable. If the check needs to be called often, then it is normally better to bind a special variable when the catch is established, and then check that variable. In situations when the check is rare (for example, it is called only in cases of error), using <b>find-throw-tag</b> is better because it eliminates the overhead of binding the special. |              |

| Description | <p>The function <code>finish-heavy-allocation</code> tells the system that the application finished doing 'heavy' allocation, and from that point onwards allocation is 'normal'. The main distinction between heavy and normal allocation is the typical lifetime of objects: normal allocation means most of new objects are ephemeral, while heavy allocation a large proportion of the new objects are long-lived.</p> <p>Heavy allocation normally happens when loading, either the application itself or large amount of data. Operations that do not involve loading will almost always be normal. Hence the time that is useful to call <code>finish-heavy-allocation</code> is after loading something.</p> |
| See also    | <code>with-heavy-allocation</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## **flag-not-special-free-action** *Function*

|           |                                                                                                                                                      |                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Summary   | Unflags an object for special action on garbage collection.                                                                                          |                                                            |
| Package   | <code>hcl</code>                                                                                                                                     |                                                            |
| Signature | <code>flag-not-special-free-action</code>                                                                                                            | <code>object =&gt; nil</code>                              |
| Arguments | <code>object</code>                                                                                                                                  | The object on which the special actions are to be removed. |
| Values    | Returns <code>nil</code> .                                                                                                                           |                                                            |
| Example   | <pre>CL-USER 1 &gt; (make-instance 'capi:title-pane) #&lt;CAPI:TITLE-PANE "" 20F9898C&gt;  CL-USER 2 &gt; (flag-not-special-free-action *) NIL</pre> |                                                            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                       |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Summary     | Flags an object for special action on garbage collection.                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                       |
| Package     | <b>hcl</b>                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                       |
| Signature   | <b>flag-special-free-action</b> <i>object</i> => t                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                       |
| Arguments   | <i>object</i>                                                                                                                                                                                                                                                                                                                                                                                                                                      | The object on which the special actions are to be performed. This cannot be a symbol. |
| Values      | Returns t.                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                       |
| Description | Note that all the current special-free-action functions are performed on the object. Use <b>flag-not-special-free-action</b> to unflag an object.                                                                                                                                                                                                                                                                                                  |                                                                                       |
| Notes       | Each object that is flagged for special free action adds some overhead to every garbage collection. This is not significant for a small number of objects, but calling <b>flag-special-free-action</b> with a large number of objects may slow the system significantly. Thus you should avoid using special free actions where possible. Normally, they should be used only for objects that keep some external resources which need to be freed. |                                                                                       |
| Example     | <pre>CL-USER 29 &gt; (make-instance 'capi:title-pane) #&lt;CAPI:TITLE-PANE "" 20F9898C&gt;  CL-USER 30 &gt; (flag-special-free-action *) T</pre>                                                                                                                                                                                                                                                                                                   |                                                                                       |

## function-information *Function*

|             |                                                                                                                                                                                                                                                                                                                        |  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Return information about the function bindings of a symbol in an environment.                                                                                                                                                                                                                                          |  |
| Package     | <b>hcl</b>                                                                                                                                                                                                                                                                                                             |  |
| Signature   | <b>function-information</b> <i>function-name</i> &optional <i>env</i> => <i>kind</i> ,<br><i>localp</i> , <i>decls</i>                                                                                                                                                                                                 |  |
| Arguments   | <i>function-name</i> A function name<br><i>env</i> An environment or <b>nil</b>                                                                                                                                                                                                                                        |  |
| Values      | <i>kind</i> Either <b>nil</b> , or one of the keywords : <b>special</b> , : <b>lexical</b> , : <b>symbol-macro</b> and : <b>constant</b> .<br><i>localp</i> A boolean<br><i>decls</i> An a-list                                                                                                                        |  |
| Description | The function <b>function-information</b> returns information about how <i>function-name</i> is bound in the environment <i>env</i> . <i>function-name</i> can be a symbol or <b>setf</b> function name.<br><br>The value of <i>kind</i> will be as follows:                                                            |  |
|             | <b>nil</b> There is no information about <i>variable</i> in <i>env</i><br><b>:macro</b> <i>function-name</i> has a macro binding in <i>env</i><br><b>:function</b> <i>function-name</i> has a function binding in <i>env</i><br><b>:special-form</b> <i>function-name</i> has a special operator binding in <i>env</i> |  |

*localp* will be true if *function-name* is bound by a form that has indefinite scope (for example `flet`) or false if *function-name* has global scope (for example `defun`).

*decls* is an a-list of declarations that refer to *function-name*. The `cdr` of each pair is specified according to the `car` of the pair as follows:

**dynamic-extent**

The `cdr` is non-nil if *function-name* is declared `dynamic-extent` in *env*.

**inline**

The `cdr` is inline or `notinline` if *function-name* is explicitly declared `inline` or `notinline` in *env*. The `cdr` is `nil` (or the pair is omitted) if this information is not known.

**ftype**

The `cdr` is the type specifier that is declared for *function-name* in *env* if any.

Notes

1. Not all of these declarations are supported.
2. `function-information` is part of the environment access API which is based on that specified in *Common Lisp: the Language (2nd Edition)*.

*Functions*

Summary

Generate "deltas", which are `code-coverage-data` objects with information for a period.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Arguments   | <code>snapshot</code> A boolean.<br><code>name</code> A Lisp object, normally a symbol or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <code>ccd</code> A <code>code-coverage-data</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description | <p>The function <code>get-code-coverage-delta</code> returns a <code>code-coverage-data</code> object with information covering the period since the previous snapshot, and with name <code>name</code>. Normally this would be set by <code>set-code-coverage-snapshot</code> or <code>get-code-coverage-delta</code> with <code>snapshot</code> non-nil. If there was no such previous call, then the "delta" period commences, for each file, from the time it was loaded.</p> <p>The function <code>reset-code-coverage-snapshot</code> eliminates any snapshot. This is useful because the snapshot uses memory.</p> <p>The function <code>set-code-coverage-snapshot</code> creates a snapshot of the internal code coverage data, to be used by <code>get-code-coverage-delta</code>.</p> <p>When <code>snapshot</code> is non-nil, <code>get-code-coverage-delta</code> sets up a new snapshot. This is more efficient than using <code>set-code-coverage-snapshot</code> again, but otherwise has the same effect. The default value of <code>snapshot</code> is <code>nil</code>.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. The functions <code>reset-code-coverage</code>, <code>clear-code-coverage</code> and <code>restore-code-coverage-data</code> also eliminate the snapshot.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

2. Code coverage manipulation functions like `subtract-code-coverage-data` can also be used to compute deltas, but `get-code-coverage-delta` will normally do it using less memory.

| Signature   | <code>gc-generation gen-num &amp;key coalesce promote block =&gt; allocation</code>                                                                                                                                                                                                                                                                    |                 |
| Arguments   | <code>gen-num</code> An integer between 0 and 7 inclusive, or <code>t</code> .<br><code>coalesce</code> A generalized boolean.<br><code>promote</code> A generalized boolean.<br><code>block</code> An integer between 0 and 7, inclusive, or one of the keywords <code>:blocking-gen-num</code> and <code>:all</code> .                               |                 |
| Values      | <code>allocation</code> The total allocation in generation <code>gen-num</code> and younger generations.                                                                                                                                                                                                                                               |                 |
| Description | <p>The function <code>gc-generation</code> does a Garbage Collection of a specific generation. The actual operation is different between 64-bit LispWorks and 32-bit LispWorks.</p> <p><code>gen-num</code> should be a valid generation number, or <code>t</code>. The value <code>t</code> is mapped to the blocking generation number in 64-bit</p> |                 |

LispWorks, and to 2 in 32-bit LispWorks. For backwards compatibility the keyword :**blocking-gen-num** is also accepted, with the same meaning as t.

It is especially helpful to GC the blocking generation (or other higher generations) when large, long-lived data structures become garbage. This is because higher generations are rarely collected by default. For the higher generations, the GC takes longer but recovers more space.

Another situation which may require **gc-generation** is when objects are marked for special free action (by **flag-special-free-action** or **free-function** in a weak hash table). If such objects live long enough to be promoted to higher generation, they may not be garbage collected long after there are no pointers to them. If the free action is important, you may need to periodically GC higher generation (typically the blocking generation, by passing **gen-num** t).

## Operation in 64-bit LispWorks

By default **gc-generation** operates on the live objects in generation **gen-num** and all lower generations at or above the generation specified by **block** by copying them inside their current generation, and it operates on the live objects in generations lower than **block** by copying them to the next higher generation.

If **promote** is non-nil, the live objects in generation **gen-num** are also promoted to the next generation. That is the same operation that happens when the GC is invoked automatically. The default value of **promote** is nil.

If **coalesce** is non-nil, all non-static live objects in lower generations are promoted to generation **gen-num**. That is what **clean-down** does (with **gen-num** being the highest generation). It may be useful directly in some cases. The default value of **coalesce** is nil.

*block* specifies a generation number up to which to promote. An integer value specifies the generation number. If *block* is :**blocking-gen-num**, then **gc-generation** promotes up to the blocking generation. If *block* is :**all**, then **gc-generation** promotes nothing. The default value of *block* is :**blocking-gen-num**.

**gc-generation** is useful when you know points in your application where many objects tend to die, or when you know that that application is less heavily loaded at some time. Typically many objects die in the end (or beginning) of an iteration in a top level loop of the application, and that is normally a useful place to put a call to **gc-generation** of generation 2 or generation 3. If you know a time when the application can spend time garbage collecting, a call to **gc-generation** with a higher value of *gen-num* may be useful. It is probably never really useful to use **gc-generation** on generation 0 or 1.

To decide on which *gen-num* to call **gc-generation**, check which generation gets full by making periodic calls to **room**.

**gc-generation** with *promote* or *coalesce* may also be useful to move objects from the blocking generation to higher generations, which does not happen automatically (except when saving the image). For example, after loading a large amount of code, and before generating any data that may die shortly, assuming the blocking generation is 3, it may be useful to do:

```
(gc-generation 4 :coalesce t)
```

to move all (non-static) objects to generation 4, where they will not be touched by the GC any more (except following pointers to younger generations).

## Operation in 32-bit LispWorks

**gc-generation** marks and sweeps the generation *gen-num* and all generations below, and then does some additional cleanups. *coalesce*, *promote* and *block* are ignored.

## Operation in the Mobile GC

When the *gen-num* argument is a number, it must be 0, 1 or 2. The value **t** (and **:blocking-gen-num**) is interpreted as 2.

Generation 0 is always promoted, but the **:promote** keyword affects generation 1 and, if non-nil, promotes even if promotion was blocked by **set-promote-generation-1**.

The keyword **:block** is ignored.

Otherwise, the function acts as in 64-bit LispWorks above.

Compatibility notes In 32-bit LispWorks, **gc-generation** simply calls **mark-and-sweep**. This has a similar effect, but two significant differences must be noted:

1. by default, **gc-generation** promotes the young generations, so repeated calls to **gc-generation** will promote everything to generation *gen-num* or generation *block* (whichever is lower). In contrast **mark-and-sweep** never promotes.
2. In 32-bit LispWorks, generation 2 is the blocking generation. In 64-bit LispWorks, the default blocking generation is generation 3. That is because the 64-bit implementation promotes faster and so needs more generations before the block.

Also note that

`(gc-generation t)`

is intended as the replacement of

`(mark-and-sweep 2)`

| Signature           | <code>gc-if-needed =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Arguments           | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Values              | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description         | This function checks to see if the amount of allocation from the previous call is more than <code>system:*allocation-inter-val*</code> , and if it is, performs a mark and sweep and promotion on generation 0. It also tries to reduce the big-chunk area. This is a fairly brief operation, and can be used whenever some operation is finished and may have left some garbage. The system itself uses it after compiling and loading files, when waiting for input, etc. |
| Notes               | <code>gc-if-needed</code> does nothing in 64-bit LispWorks.                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Description | <p>The function <code>generate-code-coverage</code> switches code coverage generation on or off.</p> <p><i>on</i> determines whether code coverage is generated. If <i>on</i> is true, code coverage generation is switched on, which means that when <code>compile-file</code> is called in the conventional way, that is generate a binary file from a source file, it generates code coverage code. If <i>on</i> is <code>nil</code>, code coverage generation is switched off and in this case the other keyword arguments are ignored. The default value of <i>on</i> is <code>t</code>.</p> <p><code>generate-code-coverage</code> returns <code>t</code> or <code>nil</code>, depending on the value of <i>on</i>.</p> <p><i>atomic-p</i> controls whether counting is done atomically or not. It is ignored when <i>counters</i> is <code>nil</code>. Passing <i>atomic-p</i> true makes the counters atomic, which may be much slower than counting non-atomically, but guarantees that the code is not going to drop counts when running multiprocessing. The default value of <i>atomic-p</i> is <code>nil</code>.</p> <p><i>counters</i> controls whether the code coverage code actually counts executions, or simply sets a flag to indicate that the code has been executed. Passing <i>counters</i> <code>nil</code> generates code</p> |            |

which is a little smaller and faster, but does not count the number of times a piece of code has been executed. The default value of *counters* is `t`.

*force*, if true, forces generating counters in code that is marked not to generate counters by `without-code-coverage` or `error-situation-forms`. The default value of *force* is `nil`.

*count-implicit-branch* controls whether to generate counters for implicit branches. Implicit branches are generated by macros like `c1:when`, where the source only contains the "then" branch, and the "else" branch (which returns `nil`) is implicit. The other macros are `c1:unless` (when it is an implicit "then"), and the switch macros `c1:cond`, `c1:case` and `c1:typecase` when they do not have a `t` or `otherwise` clause. When *count-implicit-branch* is true, the compiler generates a counter for the implicit branch, which counts the number of times that the implicit branch was executed. In other words for `c1:when` this is the number of times that the condition returned `nil`; for `c1:unless` this is the number of times that the condition returned true, and for the switch macros it is the number of times that all the clauses returned `nil`.

When coloring with an implicit branch with counter 0 inside a form with a non-zero counter, there is nowhere to put the color for the uncovered code, so the form is colored as a *hidden-partial* form (see “Understanding the code coverage output” on page 124).

The default value of *count-implicit-branch* is `t`.

## Notes

If `generate-code-coverage` is called outside the body of `with-code-coverage-generation`, it switches the generation globally. Inside the body of `with-code-coverage-generation` it switches the generation within the scope of the surrounding `with-code-coverage-generation`, but has no effect once this `with-code-coverage-generation` exited.

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the current default generation.                                                                                                                                                                                                                                                                                        |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                               |
| Signature   | <code>get-default-generation =&gt; default-gen</code>                                                                                                                                                                                                                                                                          |
| Arguments   | None.                                                                                                                                                                                                                                                                                                                          |
| Values      | Returns the current default.                                                                                                                                                                                                                                                                                                   |
| Description | By default, all new objects are allocated to a specific generation. This function returns the current value of this default generation.                                                                                                                                                                                        |
| Notes       | In 64-bit LispWorks <code>get-default-generation</code> returns 0.                                                                                                                                                                                                                                                             |

| <b>get-gc-parameters</b> |                                                                                                                                                                                    | <i>Function</i>                                                                                                                                                                                           |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                  | Returns the current values of various garbage collector parameters in 32-bit LispWorks.                                                                                            |                                                                                                                                                                                                           |
| Package                  | <code>hcl</code>                                                                                                                                                                   |                                                                                                                                                                                                           |
| Signature                | <code>get-gc-parameters <i>parameters</i> =&gt; <i>values</i></code>                                                                                                               |                                                                                                                                                                                                           |
| Arguments                | <code>parameters</code>                                                                                                                                                            | A keyword representing a single GC parameter. Any other value means all parameters.                                                                                                                       |
| Values                   | <code>values</code>                                                                                                                                                                | If <i>parameters</i> specifies a single GC parameter, the value of that parameter is returned. Otherwise <i>values</i> is an <i>alist</i> containing every GC parameter, together with its current value. |
| Description              | <p>See <code>set-gc-parameters</code> for a full description of these parameters.</p> <p>With keyword argument, of one of the parameters, the corresponding value is returned.</p> |                                                                                                                                                                                                           |
| Notes                    | <p><code>get-gc-parameters</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations.</p>                          |                                                                                                                                                                                                           |

Example      CL-USER 1 > (get-gc-parameters :minimum-overflow)  
500000

```
CL-USER 2 > (pprint (get-gc-parameters t))

((:ENLARGE-BY-SEGMENTS . 10)
 (:MINIMUM-FOR-PROMOTE . 1000)
 (:MAXIMUM-OVERFLOW . 1000000)
 (:MINIMUM-OVERFLOW . 500000)
 (:MINIMUM-BUFFER-SIZE . 200)
 (:NEW-GENERATION-SIZE . 262144)
 (:PROMOTE-MAX-BUFFER . 100000)
 (:PROMOTE-MIN-BUFFER . 200)
 (:MAXIMUM-BUFFER-SIZE . 131072)
 (:MINIMUM-FOR-SWEEP . 8000)
 (:BIG-OBJECT . 131072))
```

## **get-temp-directory** *Function*

Summary     Returns a directory that can be used for temporary files.

Package     *hcl*

Signature    **get-temp-directory** => *directory*

Values       *directory*     A pathname

Description    The function **get-temp-directory** returns a directory which is likely to be writable and can be used for temporary files.

Notes        By default, the functions **create-temp-file** and **open-temp-file** use the result of **get-temp-directory** as the directory to create their temp file in.

See also      **`create-temp-file`**  
**`example-compile-file`**  
**`open-temp-file`**

## **get-working-directory** *Function*

Summary      Finds the current working directory.

Package      **`hcl`**

Signature      **`get-working-directory => cwd`**

Arguments      None.

Values      **`cwd`**      The current working directory, as a pathname.

Description      This function is used to find the current working directory. It returns a pathname, the directory component of which is the current working directory.

Example      **`CL-USER 1 > (get-working-directory)`**  
**`#P"/u/dubya/"`**

See also      **`cd`**  
**`change-directory`**

## **gethash-ensuring** *Function*

Summary      A thread-safe way to get a value from a **`hash-table`**, adding a value if the key is not already present.

Package      **`hcl`**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                       |

|             | <i>in-lock-constructor</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A function designator for a function of one argument. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A Lisp object.                                        |
| Description | <p>The function <code>gethash-ensuring</code> gets the value for the key <i>key</i> from the hash table <i>hash-table</i>, and if this fails constructs a new value, puts it in the table and returns it. <code>gethash-ensuring</code> does this in a thread-safe way, which means that all threads calling it with the same <i>key</i> and <i>hash-table</i> return the same value (as long as nothing removes it from the table).</p> <p>If <i>key</i> is not found and <i>constructor</i> is non-nil, <i>constructor</i> is called to construct the new value. <i>constructor</i> is called without any lock, and can do whatever is needed. The value that <i>constructor</i> returns may be discarded by <code>gethash-ensuring</code> if, by the time it returns, there is already a matching value in <i>hash-table</i> (added by another thread or even inside <i>constructor</i>).</p> <p>If <i>in-lock-constructor</i> is non-nil it is called with the result of <i>constructor</i>, or with <code>nil</code> if <i>constructor</i> is <code>nil</code>. <i>in-lock-constructor</i> is called with <i>hash-table</i> locked, and its return value is guaranteed to be put in the table and to be returned by <code>gethash-ensuring</code>. If <i>in-lock-constructor</i> is <code>nil</code> then the value that is returned by <i>constructor</i>, or <code>nil</code>, is used.</p> |                                                       |
| Notes       | <ol style="list-style-type: none"> <li>1. If either the <i>constructor</i> or the <i>in-lock-constructor</i> is not simple, it is easier to use <code>with-ensuring-gethash</code>.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                       |

2. In most situations, using *constructor* to do all the work (which requires minimal holding of the lock) is better than using *in-lock-constructor*. It means that sometimes the work that *constructor* did is wasted, because another thread put the value in the table, but that overhead is normally less significant than the overhead of holding the lock for longer, with the associated potential deadlocks. Use *in-lock-constructor* only if it is essential that the result goes into the table.

**\*handle-existing-defpackage\****Variable*

Summary      Controls LispWorks’ response when `defpackage` is used on an existing package that is different from the definition given.

Package      `hcl`

Initial value      `(:warn :modify)`

Description      The standard explicitly declines to define what `defpackage` does if the named package already exists and is in a different state to that described by the `defpackage` form. The variable `*handle-existing-defpackage*` is an extension to Common Lisp which allows you to select between alternative behaviors that are known to be useful.

The two alternatives are to modify the package to conform exactly to the definition, removing features if necessary, or to merely add features specified in the `defpackage` but missing from the package. You can also control whether a condition is signaled.

The variable consists of a list of any of the following:

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <code>:error</code>   | Signal an error.                                                         |
| <code>:warn</code>    | Signal a warning.                                                        |
| <code>:add</code>     | Add the new symbols to the externals, imports, and so on.                |
| <code>:modify</code>  | Modify the package to have only these externals.                         |
| <code>:verbose</code> | The signaled errors or warnings also contain details of the differences. |

The options `:error` and `:warn` cannot be specified at the same time. One of `:add` and `:modify` must be specified. Undistinguished internals (that is, internal symbols that are not imported or shadowed), `:intern` options and sizes are ignored when deciding whether to signal.

Note that when you use `:modify` some symbols can be uninterned if `defpackage` imports another symbol with the same name from another package through `:import-from`, `:shadowing-import-from` or `:export`. This happens whether the symbol has a definition as a function, a variable, or nay other Lisp construct, so after making such a change in the package, you should re-execute the definitions that were (presumably erroneously) attached to the uninterned symbols.

| Description         | The variable <code>*handle-old-in-package*</code> controls what happens when a CLtL1-style <code>in-package</code> form is processed. This refers to the specification in Common Lisp the Language, first Edition, which preceded ANSI Common Lisp and specified <code>in-package</code> as a function with keyword arguments. |                     |                                                                           |                    |                                              |                     |                             |
|                     | The allowed values are as follows:                                                                                                                                                                                                                                                                                             |                     |                                                                           |                    |                                              |                     |                             |
|                     | <table> <tr> <td><code>:quiet</code></td> <td>Quietly use the CLtL1 definition of the <code>in-package</code> function.</td> </tr> <tr> <td><code>:warn</code></td> <td>Signal a warning and use the old definition.</td> </tr> <tr> <td><code>:error</code></td> <td>Signal a continuable error.</td> </tr> </table>          | <code>:quiet</code> | Quietly use the CLtL1 definition of the <code>in-package</code> function. | <code>:warn</code> | Signal a warning and use the old definition. | <code>:error</code> | Signal a continuable error. |
| <code>:quiet</code> | Quietly use the CLtL1 definition of the <code>in-package</code> function.                                                                                                                                                                                                                                                      |                     |                                                                           |                    |                                              |                     |                             |
| <code>:warn</code>  | Signal a warning and use the old definition.                                                                                                                                                                                                                                                                                   |                     |                                                                           |                    |                                              |                     |                             |
| <code>:error</code> | Signal a continuable error.                                                                                                                                                                                                                                                                                                    |                     |                                                                           |                    |                                              |                     |                             |

## hash-table-weak-kind                          *Function*

Summary      Returns the weak kind of a hash table.

Signature      **hash-table-weak-kind** *hash-table* => *weakness-state*

Arguments      *hash-table*      A hash table.

Values      *weakness-state*      A keyword or **nil**.

Description      The function **hash-table-weak-kind** returns the weak kind (or weakness state) of the hash table *hash-table*.  
See **set-hash-table-weak** for the meaning of the different values of *weakness-state*.

See also      **set-hash-table-weak**

|-----------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments | <i>pathname</i>       | A pathname designator naming a file which must have been created by <code>dump-forms-to-file</code> or <code>with-output-to-fasl-file</code> .                                                                                                                                                                                                                                                                                                                                                                                                                           |
|           | <i>load-args</i>      | Arguments which are passed to <code>load</code> , after removing the keyword-value pairs for <code>:allow-any-type</code> and <code>:callback</code> (if supplied).                                                                                                                                                                                                                                                                                                                                                                                                      |
|           | <i>allow-any-type</i> | A generalized boolean. When <code>allow-any-type</code> is true and the supplied <i>pathname</i> has a type, <code>load-data-file</code> tries to load it as a binary file without checking whether the type is known. When <code>allow-any-type</code> is <code>nil</code> , <code>load-data-type</code> tries to load only pathnames with known binary types (that is, either <code>*binary-file-type*</code> or in the list <code>*binary-file-types*</code> ), exactly like <code>load</code> . The default value of <code>allow-any-type</code> is <code>t</code> . |
|           | <i>callback</i>       | A function of one argument which is called with the result of the evaluation of each form in the file (or the form itself if <code>eval</code> is <code>nil</code> ). When <code>callback</code> is supplied, the keyword <code>:print</code> (which normally would be processed by <code>load</code> ) has no effect.                                                                                                                                                                                                                                                   |
|           |                       | <b>Note:</b> <code>callback</code> works only when the file was generated by LispWorks 7.0 or later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|           | <i>eval</i>           | A generalized boolean which controls whether the form is actually evaluated. When it is <code>nil</code> , the form as loaded from the file (without evaluation) is passed to the <code>callback</code> (if supplied) and printed (if <code>:print t</code> is supplied). When <code>eval</code> is non- <code>nil</code> , the form is evaluated before being passed to the <code>callback</code> and/or printed. The default value of <code>eval</code> is <code>t</code> .                                                                                            |

|             |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Values      | <i>result</i> | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |               | <p>The function <code>load-data-file</code> loads a fasl file created by <code>dump-forms-to-file</code> or <code>with-output-to-fasl-file</code>. <code>load-data-file</code> has similar semantics to <code>load</code>, but treats fasl files differently:</p> <ul style="list-style-type: none"> <li>• It cannot load a fasl generated by <code>compile-file</code>.</li> <li>• It allows loading of fasls generated by <code>dump-forms-to-file</code> or <code>with-output-to-fasl-file</code>, including those generated by a previous version of LispWorks, or other architectures of LispWorks, provided they have the same byte order.</li> <li>• It allows the option of a callback that is called on the result of loading the file.</li> </ul> <p>Fasl files generated by <code>dump-forms-to-file</code> or <code>with-output-to-fasl-file</code> must only be loaded using <code>load-data-file</code>.</p> <p><code>load-data-file</code> never loads a file as a text file, only files that are recognized as binary, which can be one of these possibilities:</p> <ul style="list-style-type: none"> <li>• <i>pathname</i> has a known type (either <code>*binary-file-type*</code> or in the list <code>*binary-file-types*</code>), or</li> <li>• <i>pathname</i> has an unknown type and <code>allow-any-type</code> is non-nil, or</li> <li>• <i>pathname</i> does not have a type and a matching file with the type matching <code>*binary-file-type*</code> is found.</li> </ul> <p>If <code>load-data-file</code> ends up trying to load a file that is not a proper binary file, it signals an error of type <code>fasl-error</code>.</p> <p>During the load, each form is loaded and, if <code>eval</code> is true, evaluated. If there is a <i>callback</i>, it is called with the result of the evaluation. Otherwise, the result may be printed if <code>:print t</code> was passed, and is then discarded.</p> |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes               | <ol style="list-style-type: none"><li>1. The default value of <code>eval</code> is <code>t</code> to give the same behavior as in LispWorks 6.1 and earlier versions. Passing <code>eval</code> as <code>nil</code> and using a callback is probably a better way of transferring data around, because it avoids the calls to <code>eval</code>. If needed, <code>callback</code> can call <code>eval</code> explicitly.</li><li>2. All x86/x64 and ARM architectures have the same byte order, so <code>load-data-file</code> on any x86/x64 or ARM architecture can be used to load a data file that was generated on any x86/x64 or ARM architecture. The reverse byte order is used by Power architecture (IBM AIX and old PowerPC Mac OS X) and SPARC (old Solaris).</li><li>3. <code>load-data-file</code> returns the same value as <code>load</code>. In particular, the return value has nothing to do with the forms in the file. To actually have an effect, either the forms themselves have side effects, or the <code>callback</code> argument is used to perform any required side effects.</li><li>4. <code>load-data-file</code> does not do any read operation, but if the forms in the file contain symbols (except <code>nil</code>) such symbols need to be interned.</li></ol> |
| Compatibility notes | <ol style="list-style-type: none"><li>1. In LispWorks 6.1 and earlier versions <code>load-data-file</code> was in the <code>SYSTEM</code> package. It is still exported from <code>SYSTEM</code> for backwards compatibility.</li><li>2. In LispWorks 6.1 and earlier versions <code>load-data-file</code> gave errors if the type was not recognized, but now by default it allows any type.</li><li>3. In LispWorks 6.1 and earlier versions <code>load-data-file</code>, when given a plain lisp file, would load it the same way that <code>load</code> does. In LispWorks 7.0 or later it signals an error of type <code>fasl-error</code>.</li><li>4. <code>callback</code> works only when the fasl file was generated by LispWorks 7.0 or later.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Examples            | For a simple example see <code>dump-forms-to-file</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**\*load-fasl-or-lisp-file\*** *Variable*

Summary Controls the behavior of `load` for untyped pathnames.

Package `hcl`

Description The variable `*load-fasl-or-lisp-file*` determines whether `(load "foo")` should load the binary file `(foo.ofasl, foo.ufasl, foo.xfasl` etc, depending on platform) or `foo.lisp`, when both exist. It may take the following values:

- `:load-newer` If the fasl is out-of-date, the lisp file is loaded, and a warning message is output in verbose mode.
- `:load-newer-no-warn`  
Like `:load-newer`, but without the warning.
- `:load-fasl` Always choose fasl files in preference to lisp files, but when verbose, warn if the lisp file is newer.
- `:load-fasl-no-warn`  
Like `:load-fasl`, but without the warning.
- `:load-lisp` Always choose lisp files in preference to fasl.
- `:recompile` If the fasl file is out-of-date or there is none, compile and load the new fasl.
- `:maybe-recompile`

If the fasl is out-of-date, queries whether to load it, recompile and then load it, or load the lisp file.

Initial value :**load-fasl**

| Values                 | <i>ring</i> A "ring" object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                    |             |           |                        |                                                       |
| Description            | <p>The function <b>make-ring</b> creates a "ring" object, which can hold up to <i>size</i> elements. A ring has stack like behavior but is limited in size, and can be rotated.</p> <p><i>size</i> is the maximum number of elements that the ring <i>ring</i> can hold. Once <i>ring</i> has this number of elements, if an element is added to <i>ring</i> (by <b>ring-push</b>), an element is first removed from the ring.</p> <p><i>name</i> simply names the ring, but has no effect on its functionality. It is used when printing the ring object, and is returned by <b>ring-name</b>.</p> <p><i>delete-function</i>, if supplied, is called each time an element is removed from the ring (by <b>ring-push</b>) because it is full. The default value of <i>delete-function</i> is #'<b>identity</b>.</p> |             |                    |             |           |                        |                                                       |

The ring keeps the elements in a logical ring with an "insertion position". The function `ring-push` adds an element before the insertion position. If the ring is full, it first removes the element immediately after the insertion position.

The function `ring-pop` removes from the ring the element before the insertion point, and returns that element. Thus when using `ring-push` and `ring-pop` on their own, the ring behaves like a stack with limited length.

`rotate-ring` can be used to move the insertion point. `ring-ref` can be used to index into the ring. `map-ring`, `position-in-ring`, and `position-in-ring-forward` can be used to iterate through the ring's elements.

All access to a ring is thread-safe. Therefore access to a ring may hang if another process keeps it locked. If you need to guarantee no hanging, you can use `with-ring-locked` with non-nil `timeout` around the critical calls.

Summary      Create and use an `unlocked-queue` object.

Package      `hcl`

Signature      `make-unlocked-queue &key size name => unlocked-queue`  
`unlocked-queue-read unlocked-queue => object`  
`unlocked-queue-peek unlocked-queue => object`  
`unlocked-queue-ready unlocked-queue => result`  
`unlocked-queue-send unlocked-queue object => object`  
`unlocked-queue-count unlocked-queue => count`  
`unlocked-queue-size unlocked-queue object => size`

Arguments      `size`      A positive integer.

`name`      A Lisp object.

`unlocked-queue`      An `unlocked-queue` object.

`object`      A Lisp object.

Values      `count`      A positive integer.

`object`      A Lisp object.

`result`      A boolean.

`size`      A positive integer.

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>make-unlocked-queue</code> creates a new, empty <code>unlocked-queue</code> object.</p> <p>The functions <code>unlocked-queue-read</code>, <code>unlocked-queue-peek</code>, <code>unlocked-queue-ready</code>, <code>unlocked-queue-send</code>, <code>unlocked-queue-count</code> and <code>unlocked-queue-size</code> use an <code>unlocked-queue</code> object.</p> <p><code>size</code> is a hint of the maximum number of objects that are expected to be in the queue simultaneously. The queue is extended as needed, so <code>size</code> does not have to be a good guess.</p> <p><code>name</code> is used when printing the <code>unlocked-queue</code> and so it is useful for debugging. <code>name</code> is not used otherwise.</p> <p><code>unlocked-queue-read</code> checks whether there is anything in the queue, and if so removes the first object in the queue and returns it. Otherwise it returns <code>nil</code>.</p> <p><code>unlocked-queue-peek</code> checks whether there is anything in the queue, and if so returns the first object in the queue without modifying the queue. Otherwise it returns <code>nil</code>.</p> <p><code>unlocked-queue-ready</code> returns a boolean specifying whether there is anything in the queue.</p> <p><code>unlocked-queue-send</code> adds <i>object</i> to the end of the queue, extending the queue if needed. It returns its second argument.</p> <p><code>unlocked-queue-count</code> returns the number of objects in the queue.</p> <p><code>unlocked-queue-size</code> returns the current size of the queue. Note that it is increased when needed by <code>unlocked-queue-send</code></p> |

| Description | <p>The function <code>map-code-coverage-data</code> maps <i>function</i> over the files in <i>ccd</i> and optionally collects items for some of them. If <i>ccd</i> is <code>t</code>, this is interpreted as the internal <code>code-coverage-data</code> object.</p> <p>The arguments passed to <i>function</i> depend on <i>without-stats</i>. If <i>without-stats</i> is false then <i>function</i> is called with the truename and a <code>code-coverage-file-stats</code> object for the file. If <i>without-stats</i> is true, then <i>function</i> is applied only to the truename. The default value of <i>without-stats</i> is false.</p> <p>If <i>collect</i> is <code>t</code> (the default), then <code>map-code-coverage-data</code> collects the stats (when <i>without-stats</i> is false) or the truename (when <i>without-stats</i> is true) for each call to <i>function</i> that returns true. If <i>collect</i> is <code>:truenames</code>, then <code>map-code-coverage-data</code> collects the truename for each call to <i>function</i> that returns true.</p> <p>When <i>collect</i> is <code>nil</code>, <code>map-code-coverage-data</code> returns <code>nil</code>. Otherwise, it returns a list of the objects it collected.</p> |                 |

## **map-ring** *Function*

Summary      Calls a function on each element of a ring, modifying the element.

Package      **`hcl`**

Signature      **`map-ring ring function`**

Arguments      *ring*      A ring object created by **`make-ring`**.

*function*      A function designator for a function of one argument.

Description      The function **`map-ring`** funcalls the function *function* on each element in the ring in turn, and sets that ring element to the result.

Notes      1. *function* is called with the ring locked.

                  2. If you do not intend to modify the elements of *ring*, ensure that *function* returns its argument.

## **mark-and-sweep** *Function*

Summary      Garbage collects a specified generation in 32-bit LispWorks.  
This function is deprecated: use **`gc-generation`** instead.

| Arguments   | <p><code>gen-number</code>      0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <p><code>bytes</code>      The number of bytes allocated in that generation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p><code>mark-and-sweep</code> is used to garbage-collect a specified generation of memory (and all lower generations). A call to this function forces the garbage collector to scan the specified generations. This can be of use in obtaining consistent timings of programs that require memory allocation. Alternatively, performance can sometimes be improved by forcing a garbage collection, when it is known that little memory has been allocated since a previous collection, rather than waiting for a later, more extensive collection. For example, the function could be called outside a loop that allocates a small amount of memory.</p> <p>It is specially helpful to mark and sweep generation 2 when large, long-lived data structures become garbage, because by default it is never marked and swept. The higher the generation number the more time the <code>mark-and-sweep</code> takes, but also the more space recovered.</p> |
| Notes       | <p><code>mark-and-sweep</code> is implemented only in 32-bit LispWorks, and is deprecated. Use <code>gc-generation</code> instead.</p> <p><code>mark-and-sweep</code> is not relevant to the Memory Management API in 64-bit implementations. In 64-bit implementations you can use <code>gc-generation</code> or <code>marking-gc</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Examples    | <pre>(mark-and-sweep 0) ; collect most recent generation (mark-and-sweep 3) ; collect all generations</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**\*max-trace-indent\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The maximum level of indentation used in trace output.                                                                                                                                                                                                                                                             |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                   |
| Initial value | 50                                                                                                                                                                                                                                                                                                                 |
| Description   | <code>*max-trace-indent*</code> is the maximum indentation that is used during output from tracing. Typically each successive invocation of tracing causes the output to be further indented, making it easier to see how the calls are nested. The value of <code>*max-trace-indent*</code> should be an integer. |
| Example       | <pre>USER 8 &gt; (setq hcl:*max-trace-indent* 4) 4 USER 9 &gt; (defun sum (n res) (if (= n 0)                                 res                                 (+ n (sum (1- n) res)))) SUM  USER 10 &gt; (trace sum) SUM</pre>                                                                                 |

```

USER 11 > (sum 3 0)
0 SUM > (3 0)
1 SUM > (2 0)
2 SUM > (1 0)
3 SUM > (0 0)
3 SUM < (0)
2 SUM < (1)
1 SUM < (3)
0 SUM < (6)
6

```

Notes      \*`max-trace-indent`\* is an extension to Common Lisp.

## `merge-code-coverage-data`

## `destructive-merge-code-coverage-data`

*Functions*

Summary      Merge two `code-coverage-data` objects.

Package      `hcl`

Signature      `merge-code-coverage-data ccd1 ccd2 name => result`

`destructive-merge-code-coverage-data ccd1 ccd2 => ccd1`

Arguments      `ccd1`      A `code-coverage-data` object or (for  
`merge-code-coverage-data` only) t.

`ccd2`      A `code-coverage-data` object or t.

`name`      A Lisp object, normally a symbol or a string.

Values      `result`      A `code-coverage-data` object.

Description      The function `merge-code-coverage-data` and `destructive-merge-code-coverage-data` merge two `code-coverage-data` objects.

Merging means taking all the files from *ccd1* together with those files from *ccd2* which do not have information in *ccd1*. For files that appear in both *ccd1* and *ccd2*, the information in *ccd2* is ignored.

`merge-code-coverage-data` creates a new `code-coverage-data` object containing the information for each file, and with name *name*.

`destructive-merge-code-coverage-data` adds to *ccd1* those files from *ccd2* which are not already there, and returns *ccd1*.

If either of the datas is the internal `code-coverage-data` object, the file information is copied, so it does not change anymore. Otherwise it just copies the pointer, because the file information is read-only.

`code-coverage-data`

## modify-hash *Function*

Summary      Reads and writes an entry in a hash table atomically.

Package      `hcl`

Signature      `modify-hash hash-table key function => new-value, key`

Arguments      `hash-table`      A hash table.

`key`          An object.

`function`     A function designator.

Values      `new-value`      An object.

`key`          An object.

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>modify-hash</code> locks the hash table <i>hash-table</i>. It then calls the function <i>function</i> with three arguments: <i>key</i>, the value currently associated with <i>key</i> in <i>hash-table</i> (if any), and a flag which is true if the key was in the table. (This last argument is needed in case the associated value is <code>nil</code>).</p> <p><code>modify-hash</code> then sets the result of the function <i>function</i> as the value for <i>key</i> in the table. <code>modify-hash</code> returns two values, the <i>new-value</i> and the <i>key</i>.</p> <p>The overall effect is like:</p> <pre>(with-hash-table-locked   hash-table   (multiple-value-bind (value found-p)     (gethash key hash-table)     (let ((new-value (funcall function                                key value found-p)))       (setf (gethash key hash-table) new-value)       (values new-value key))))</pre> <p>but <code>modify-hash</code> should be more efficient.</p> <p>It is guaranteed that no other thread can modify the value associated with <i>key</i> until <code>modify-hash</code> returns.</p> |
| Notes       | <i>function</i> is called with <i>hash-table</i> locked, so it should not do anything that may require hanging the modification, or that waits for another process that tries to modify the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                          |
| Signature   | <code>normal-gc =&gt; t</code>                                                                                                                                                                                                                                                            |
| Arguments   | None.                                                                                                                                                                                                                                                                                     |
| Values      | The function returns the single result <code>t</code> .                                                                                                                                                                                                                                   |
| Description | <p><code>normal-gc</code> resets various internal parameters that determine the frequency and extent of garbage collection to their default settings.</p> <p><code>normal-gc</code> is generally used in conjunction with <code>avoid-gc</code>, to cancel the effects of the latter.</p> |
| Notes       | <code>normal-gc</code> is useful only in 32-bit LispWorks. In 64-bit implementations it does nothing and simply returns <code>nil</code> .                                                                                                                                                |

| <b>*packages-for-warn-on-redefinition*</b> |                                                                                      | <i>Variable</i> |
|--------------------------------------------|--------------------------------------------------------------------------------------|-----------------|
| Summary                                    | A list specifying packages whose symbols should be checked on attempted definitions. |                 |
| Package                                    | <code>hcl</code>                                                                     |                 |
| Initial value                              | <code>(:implementation)</code>                                                       |                 |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The variable <code>*packages-for-warn-on-redefinition*</code> is a list of package names or the keyword <code>:implementation</code>, specifying packages which are "protected". For "protected" packages, LispWorks checks before defining (using any of the definer macros like <code>c1:defun</code>, <code>c1:defclass</code> and so on) any external symbol of these packages, and takes the action specified by <code>*handle-warn-on-redefinition*</code> (which defaults to signaling an error).</p> <p>The symbol <code>:implementation</code> in <code>*packages-for-warn-on-redefinition*</code> indicates all of the packages which are part of the LispWorks implementation. That includes all the documented packages, including COMMON-LISP and KEYWORD but excluding some "user" packages like CL-USER and KW-USER, and some packages that are used internally.</p> <p>For symbol value, setting and rebinding is not checked, but defining using definer macros like <code>c1:defvar</code> and <code>c1:define-parameter</code> is checked.</p> |
| Notes       | <ol style="list-style-type: none"><li>1. The checking is useful because it is relatively easy to redefine an external symbol by mistake, and it leads to undefined behavior which is difficult to debug. It is therefore a bad idea to remove <code>:implementation</code> from the list. In situations when this is required, you should do it by rebinding <code>*packages-for-warn-on-redefinition*</code> rather than setting it.</li><li>2. You can protect your packages by adding their package names to this list.</li><li>3. The check is applied for any definition, whether it is actually a redefinition or not. For example, trying to define the symbol <code>c1:stream</code> as a function gives an error (by default), even though <code>c1:stream</code> has only a class definition, and trying to define <code>c1:car</code> as a class also errors even though <code>c1:car</code> has only a function definition.</li></ol>                                                                                                                    |

4. You can check whether a package is an implementation package by using `package-flagged-p` with the keyword `:implementation`.

|                    |                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility note | <code>:implementation</code> was new in LispWorks 7.0.<br>In LispWorks 6.1 and earlier versions, the list could contain only package names, and the initial value was a long list of package names. |
| See also           | <code>*handle-warn-on-redefinition*</code><br><code>package-flagged-p</code><br>“Protecting packages” on page 88                                                                                    |

## parse-float *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                   |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Parses a float from a string and returns it as <code>float</code> .                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                   |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                   |

| Values      | <code>float</code>                                                                                                                                                                                                                                                                                                                                                                                                               | A float                                                                                                                                           |
| Description | <p>The function <code>parse-float</code> parses a float from the substring of <code>string</code> delimited by <code>start</code> and <code>end</code> and returns it as <code>float</code>. If the substring represents an integer or the exponent marker is E or is omitted, then <code>float</code> will be of type <code>default-format</code>, which defaults to the value of <code>*read-default-float-format*</code>.</p> |                                                                                                                                                   |

`mat*`. Otherwise, its type will match the exponent marker as specified by 2.3.2.2 "Syntax of a Float" in the Common Lisp standard.

If the substring does not represent an integer or a float, then an error of type `parse-error` is signaled.

### Examples

```
(parse-float "10") => 10.0f0
(parse-float "10" :default-format 'double-float) =>
10.0d0
(parse-float "10d0") => 10.0d0
(parse-float "10.5") => 10.5f0
(parse-float "10.5d0") => 10.5d0
```

## position-in-ring

## position-in-ring-forward

## *Functions*

**Summary**      Finds the first ring element that matches a supplied item and returns its index.

**Package**      `hcl`

**Signature**      `position-in-ring ring item index &key test => result`  
`position-in-ring-forward ring item index &key test => result`

**Arguments**      `ring`      A ring object created by `make-ring`.

`index`      A non-negative integer.

`item`      A Lisp object.

`test`      A function designator for a function of two arguments.

**Values**      `result`      A non-negative integer or `nil`.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description         | <p>The function <b>position-in-ring</b> finds in the ring <i>ring</i> the first element that matches <i>item</i> and returns its index, or <b>nil</b> if there is no match. The search starts from index <i>index</i> and proceeds "backward" up to the length of the ring (its current number of elements). In other words, it tests all the elements that would be returned by <b>ring-ref</b> with indices <i>index</i>, <i>index+1</i>, ..., <i>length-1</i>. It does not wrap around, so elements between indices 0 and <i>index</i> are not tested.</p> <p>The function <b>position-in-ring-forward</b> does the same except that it searches from <i>index</i> "forward" to the insertion point. In other words, it tests the elements that would be returned by <b>ring-ref</b> with indices <i>index</i>, <i>index-1</i>, ..., 0.</p> <p>The comparison is done by calling <i>test</i>, with <i>item</i> as first argument and each element in the ring as the second argument. The default value of <i>test</i> is <b>eq1</b>.</p> |
| Notes               | <i>test</i> is called with the ring locked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Compatibility notes | In LispWorks 6.1 and earlier versions, these functions are called <b>find-in-ring</b> and <b>find-in-ring-forward</b> . They have been renamed to match the Common Lisp convention that a function returning an index is named <b>position-*</b> . The old names are retained for backwards compatibility, but are deprecated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|             | <i>collapse</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A generalized boolean.  |
|             | <i>cutoff</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A real number.          |
| Values      | <code>print-profile-list</code> returns nil.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                         |
| Description | <p>The function <code>print-profile-list</code> prints a report of symbols, after profiling using <code>profile</code>, or <code>start-profiling</code> followed by <code>stop-profiling</code>.</p> <p>If the profiler was set up with <code>style :tree</code>, then a tree of calls is printed first, according to <i>limit</i>, <i>cutoff</i> and <i>collapse</i>. Then a columnar report is printed showing how often each function was called, profiled and found on the top of the stack. This report is sorted by the column indicated by the value of <i>sort</i>.</p> <p>If the profiler was set up with <code>style :list</code>, then only the columnar report is printed.</p> <p><i>sort</i> can take these values:</p> <ul style="list-style-type: none"> <li>:call Sort by the number of times the function was called.</li> <li>:profile Sort by the number of times the function was found on the stack.</li> <li>:top Sort by the number of times the function was found at the top of the stack.</li> </ul> <p>If <i>sort</i> is not passed then the results are printed as after the profiling run. The default is the value of the variable <code>*default-profiler-sort*</code>.</p> <p><i>limit</i> is the maximum number of lines printed in the columnar report as described for <code>*default-profiler-limit*</code>. The default is the value of the variable <code>*default-profiler-limit*</code>.</p> |                         |

*cutoff* is the minimum percentage that the profiler will display in the output tree as described for **\*default-profiler-cutoff\***. The default is the value of the variable **\*default-profiler-cutoff\***.

*collapse* controls collapsing of the output tree as described for **\*default-profiler-collapse\***. The default is the value of the variable **\*default-profiler-collapse\***.

Notes You should not call **print-profile-list** while the profiler is running (see **profile** and **start-profiling**) or suspended (see **stop-profiling**).

Example First set up the profiler :

```
CL-USER 1 > (set-up-profiler
                 :symbols
                 '(cadr car eql fixnump + 1+ caaddr caddr))

CL-USER 2 > (profile (dotimes (a 1000000 nil)
                         (+ a a)
                         (car '(foo))))
```

Then call **print-profile-list**:

```

CL-USER 3 > (print-profile-list :sort :call)

profile-stacks called 327 times

Cumulative profile summary
Symbol          called   profile
(%)      top   (%)
CADR           5000012    13
( 4)        13 ( 4)
CDDR           3000000    3
( 1)        3 ( 1)
EQL            2000202    4
( 1)        4 ( 1)
FIXNUMP         2000003    2
( 1)        2 ( 1)
CAR             1000000    1
( 0)        1 ( 0)
+               1000000    3
( 1)        3 ( 1)
CAADR          1000000    2
( 1)        2 ( 1)
1+             1000000    2
( 1)        2 ( 1)

Top of stack not monitored 91% of the time
NIL

```

**Notes** You can suppress printing of those symbols that are currently profiled but which were not called in the profiling run by setting `system:*profiler-print-out-all*` to `nil`.

`system:*profiler-print-out-all*` is a variable defined when the profiler is loaded by `set-up-profiler`. Its initial value is `nil`.

**See also** `*default-profiler-collapse*`  
`*default-profiler-cutoff*`  
`*default-profiler-limit*`  
`*default-profiler-sort*`

## **\*print-string\*** *Variable*

Summary     Specifies a maximum length when printing strings.

Package     `hcl`

Initial value     `t`

Description     The variable `*print-string*` controls whether the printer uses an abbreviated form for strings when `*print-escape*` is true.

If the value of `*print-string*` is `t` then strings are printed in full as specified by ANSI Common Lisp.

If the value of `*print-string*` is `nil`, then strings are printed as unreadable objects with no specific information about the string.

If the value of `*print-string*` is an integer, then strings longer than `*print-string*` are printed as unreadable objects that include the type, length and first `*print-string*` characters.

## **profile** *Macro*

Summary     Profile while executing some forms.

Package     `hcl`

Signature     `profile &body forms => results-of-final-form`

Arguments     `forms`     Lisp forms.

Values     `results-of-final-form`Results of the final form in `forms`.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <b>profile</b> starts the profiler, evaluates <i>forms</i> , stops the profiler, reports the results of the profiling, and then returns the results of the last form in <i>forms</i> .<br><br>The profiler is described in Chapter 12, “The Profiler”.                                                                                                                                                                     |
| Note        | <b>profile</b> profiles all processes. For better control of this, use <b>start-profiling</b> or <b>do-profiling</b> .<br><br>If <b>profile</b> is invoked before <b>set-up-profiler</b> was ever called, it calls <b>set-up-profiler</b> implicitly without arguments.<br><br><b>profile</b> cannot be called while another profiling operation is running, either by a parallel call to <b>profile</b> or <b>start-profiling</b> . |

| Package                      | <code>hcl</code>                                                                                                                                                                                                                                                                                                                           |
| Description                  | <code>*profile-symbol-list*</code> is the list of symbols that are profiled if <code>profile</code> is called. Symbols in this list are monitored by the profiler to see if their function objects are on the stack when the profiler interrupts the Lisp process. The length of this list does not affect the speed of the profiling run. |
| Initial value                | <code>nil</code>                                                                                                                                                                                                                                                                                                                           |
| Notes                        | <code>*profile-symbol-list*</code> should normally be set by one of the above functions which check that the symbol is suitable for profiling before adding them to the list.                                                                                                                                                              |
| See also                     | <code>add-symbol-profiler</code><br><code>remove-symbol-profiler</code><br><code>set-up-profiler</code>                                                                                                                                                                                                                                    |

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>profiler-tree-from-function</code> prints a tree with root <i>function-name</i> whose children are the callees of <i>function-name</i> and their callees.</p> <p><code>profiler-tree-from-function</code> uses the data from the previous 'profile session' with style <code>:tree</code>. A profile session ends at the end of <code>profile</code> or when <code>stop-profiling</code> is called, or when the Profiler tool finishes profiling.</p> <p>In both cases the counts of profile calls is the total counts of the calls to <i>function-name</i>. Note that the percentages (the number in parentheses) are percentages from the total number of profile calls, rather than from the numbers of calls to <i>function-name</i>.</p> <p>If <i>max-depth</i> is a number it limits the depth of tree that is printed to that value. The default value of <i>max-depth</i> is <code>nil</code>, meaning no limit on the depth that is printed.</p> |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>profiler-tree-to-function</code> prints a tree with root <i>function-name</i> whose children are the callers of <i>function-name</i> and their callers. Note that the tree is reversed, that is, callers appear under their callees.</p> <p><code>profiler-tree-to-function</code> uses the data from the previous 'profile session' with style <code>:tree</code>. A profile session ends at the end of <code>profile</code> or when <code>stop-profiling</code> is called, or when the Profiler tool finishes profiling.</p> <p>In both cases the counts of profile calls is the total counts of the calls to <i>function-name</i>. Note that the percentages (the number in parentheses) are percentages from the total number of profile calls, rather than from the numbers of calls to <i>function-name</i>.</p> <p><i>max-depth</i> limits the depth of tree that is printed. If <i>max-depth</i> is <code>nil</code> there is no limit on the depth that is printed. The default value of <i>max-depth</i> is 7.</p> |

|-----------|-----------------------|-------------------------------------------------------------------------------------------|
| Summary   |                       | Attempts to reduce the size of the Lisp image, without enlarging it even temporarily.     |
| Package   |                       | <code>hcl</code>                                                                          |
| Signature |                       | <code>reduce-memory &amp;optional full =&gt; new-size</code>                              |
| Arguments | <code>full</code>     | <code>nil</code> or <code>t</code> (or 0, 1, 2 or <code>:aggressive</code> on Mobile GC). |
| Values    | <code>new-size</code> | A positive integer.                                                                       |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>reduce-memory</code> frees memory and tries to reduce the size of the Lisp image, without enlarging it even temporarily.</p> <p><code>reduce-memory</code> has the same effect as <code>clean-down</code>, except that <code>clean-down</code> may temporarily increase the size of the image in order to be able to promote from lower generations. <code>reduce-memory</code> never increases the image size, which means that it may fail to promote. This will cause future garbage collections to be slower, until the promotion actually occurs.</p> <p><code>reduce-memory</code> is intended to be used when the operating system signals that the memory is low, which is a common feature of mobile platforms, for example <code>onTrimMemory</code> and <code>onLowMemory</code> in Android and <code>didReceiveMemoryWarning</code> in iOS. Using <code>clean-down</code> in this situation may cause a temporary increase in size, which may cause the system to run out of memory, or maybe just kill the Lisp process. In other circumstances <code>clean-down</code> should do a better job (and you might also consider <code>try-move-in-generation</code>).</p> <p>In 32-bit LispWorks, if <code>full</code> is <code>nil</code>, <code>reduce-memory</code> frees memory and promotes live objects to generation 2. When <code>full</code> is non-<code>nil</code>, <code>reduce-memory</code> frees and promotes to generation 3.</p> <p>In ordinary (Sparse) 64-bit LispWorks, <code>full</code> is ignored. The call just frees what it can free easily.</p> <p>When using the Mobile GC, if <code>full</code> is <code>nil</code>, <code>reduce-memory</code> just frees what it can free easily. If <code>full</code> is <code>t</code>, <code>reduce-memory</code> performs a garbage collection on generation 2 and then frees what it can free easily. If <code>full</code> is <code>:aggressive</code>, <code>reduce-memory</code> performs one or more garbage collections until memory is no longer being freed and then frees what it can free easily.</p> <p>When <code>full</code> is a integer (0, 1 or 2), it specifies a generation number to garbage collect and <code>reduce-memory</code> garbage collects this generation and then frees what it can free easily. Using 2 is the same as using <code>t</code>.</p> <p>The default value of <code>full</code> is <code>nil</code>.</p> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`reduce-memory` returns the new size of the Lisp image after reduction, in bytes.

- Notes
1. The default of *full* is `nil`, which is different from `clean-down` where it defaults to `t`.
  2. In 32-bit LispWorks, `reduce-memory` with no argument or `nil` differs from `(clean-down nil)` by trying to reduce the memory. `(clean-down nil)` frees and promotes, but does not try to reduce the size (and may actually increase it).
  3. When using the Mobile GC, `reduce-memory` releases any reserved memory that the system keeps. As a result any following `reduce-memory` with argument non-`nil` will be less effective because there will be no reserved memory to perform copying garbage collection.

## **remove-symbol-profiler** *Function*

|             |                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| Summary     | Deprecated. Removes a symbol from the list of profiled symbols.                                                        |
| Package     | <code>hcl</code>                                                                                                       |
| Signature   | <code>remove-symbol-profiler symbol =&gt; nil</code>                                                                   |
| Arguments   | <code>symbol</code> A symbol to be removed from the <code>*profile-symbol-list*</code> .                               |
| Values      | Returns <code>nil</code> .                                                                                             |
| Description | The function <code>remove-symbol-profiler</code> is deprecated. It removes a symbol from the list of profiled symbols. |
| See also    | <code>add-symbol-profiler</code>                                                                                       |

## **reset-profiler** *Function*

|           |                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Resets the profiler so that symbols below a given threshold are no longer profiled.                                                                                                                                                                                                               |
| Package   | <code>hcl</code>                                                                                                                                                                                                                                                                                  |
| Signature | <code>reset-profiler &amp;key according-to =&gt; nil</code>                                                                                                                                                                                                                                       |
| Arguments | <code>according-to</code> One of two values — <code>:profile</code> or <code>:top</code> . This refers to which column of the profiling results <code>reset-profiler</code> uses to determine which symbols to delete from the list of symbols to profile. The default is <code>:profile</code> . |
| Values    | <code>reset-profiler</code> returns <code>nil</code> .                                                                                                                                                                                                                                            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | This function updates the list of symbols being profiled according to the results of the previous profiling run. <code>reset-profiler</code> runs down the list of symbols being profiled and removes any symbols whose appearance in the previous profiling run falls below the value <code>*profiler-threshold*</code> . In this way the number of symbols being considered by the profiler can be reduced to just those which are important. |
| Example     | <code>(reset-profiler :according-to :top)</code>                                                                                                                                                                                                                                                                                                                                                                                                |
| Notes       | Reducing the number of symbols in the list of symbols to profile does not actually speed up the execution of the form being profiled, but does reduce the setting up time of the profiler and the size of the list of results.                                                                                                                                                                                                                  |
| See also    | <code>profile</code><br><code>*profiler-threshold*</code><br><code>print-profile-list</code><br><code>set-profiler-threshold</code>                                                                                                                                                                                                                                                                                                             |

| <b>reset-ring</b> |                                                                                                            | <i>Function</i>                                   |
|-------------------|------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Summary           | Resets a ring.                                                                                             |                                                   |
| Package           | <code>hcl</code>                                                                                           |                                                   |
| Signature         | <code>reset-ring ring =&gt; nil</code>                                                                     |                                                   |
| Arguments         | <code>ring</code>                                                                                          | A ring object created by <code>make-ring</code> . |
| Description       | The function <code>reset-ring</code> resets the ring, that is it makes <code>ring</code> completely empty. |                                                   |
| See also          | <code>make-ring</code>                                                                                     |                                                   |

## **ringp**

### *Function*

|             |                                                                                                               |                |
|-------------|---------------------------------------------------------------------------------------------------------------|----------------|
| Summary     | The predicate for rings.                                                                                      |                |
| Package     | <code>hcl</code>                                                                                              |                |
| Signature   | <code>ringp object =&gt; result</code>                                                                        |                |
| Arguments   | <code>object</code>                                                                                           | A Lisp object. |
| Values      | <code>result</code>                                                                                           | A boolean.     |
| Description | The function <code>ringp</code> is a predicate for rings, that is objects created by <code>make-ring</code> . |                |
| See also    | <code>make-ring</code>                                                                                        |                |

## **ring-length**

### *Function*

|             |                                                                                                                                |                                                   |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Summary     | Gets the element count and maximum size of a ring.                                                                             |                                                   |
| Package     | <code>hcl</code>                                                                                                               |                                                   |
| Signature   | <code>ring-length ring =&gt; number-of-elements, size</code>                                                                   |                                                   |
| Arguments   | <code>ring</code>                                                                                                              | A ring object created by <code>make-ring</code> . |
| Values      | <code>number-of-elements</code>                                                                                                | A non-negative fixnum.                            |
|             | <code>size</code>                                                                                                              | A positive fixnum.                                |
| Description | The function <code>ring-length</code> returns as multiple values the number of elements in the ring ring and its maximum size. |                                                   |
| See also    | <code>make-ring</code>                                                                                                         |                                                   |

| <b>ring-name</b> | <i>Function</i>                                                                                                                                                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary          | Returns the name of a ring.                                                                                                                                                                                                                                                                                |
| Package          | <code>hcl</code>                                                                                                                                                                                                                                                                                           |

| <b>ring-pop</b>  | <i>Function</i>                                                                                                                                                                                                                                                                                            |
| Summary          | Removes an element from a ring and returns the element before the insertion point.                                                                                                                                                                                                                         |
| Package          | <code>hcl</code>                                                                                                                                                                                                                                                                                           |
| Signature        | <code>ring-pop ring &amp;optional remove =&gt; object</code>                                                                                                                                                                                                                                               |
| Arguments        | <code>ring</code> A ring object created by <code>make-ring</code> .<br><code>remove</code> A generalized boolean.                                                                                                                                                                                          |
| Values           | <code>object</code> A Lisp object.                                                                                                                                                                                                                                                                         |
| Description      | The function <code>ring-pop</code> removes (by default) an element from the ring and returns the element before the insertion point.<br>If <code>remove</code> is true then the element is removed from the ring. If <code>remove</code> is <code>nil</code> then the element remains and instead the ring |

is rotated by 1 as if by (`rotate-ring ring 1`). The default value of `remove` is `t`.

`ring-pop` signals an error when called on an empty ring.

**Examples** These 3 forms all return the same values, but the first form removes an element from the ring, while the other two leave all the elements in the ring:

```
(values (ring-pop ring) (ring-ref ring 0))  
(values (ring-pop ring t) (ring-ref ring 0))  
(values (ring-ref ring 0) (rotate-ring ring 1))
```

## **ring-push** *Function*

**Summary** Adds a Lisp object to a ring.

**Package** `hcl`

**Signature** `ring-push object ring => object`

**Arguments** `object` A Lisp object.

`ring` A ring object created by `make-ring`.

**Values** `object` A Lisp object.

**Description** The function `ring-push` adds any Lisp object as an element of the ring before the "insertion position", which means that a following `ring-pop` will return it. If the ring is full, that is the number of elements in the ring is the same as its size (see

`make-ring`), then `ring-push` first removes the element after the insertion point.

Once it finished modifying the ring, if `ring-push` removed an element and there is a *delete-function* (see `make-ring`), then `ring-push` calls *delete-function* on the element that it removes.

`ring-push` returns *object*.

## **ring-ref** *Function*

Summary      Gets or sets the element at a specified offset from the insertion point in a ring.

Package      `hcl`

Signature      `ring-ref ring index => object`  
`(setf ring-ref) object ring index`

Arguments      `ring`      A ring object created by `make-ring`.

`index`      A non-negative integer.

`object`     A Lisp object.

Values      `object`      A Lisp object.

Description      The function `ring-ref` returns or sets the element at *index* places before the insertion point in the ring *ring*.

*index* must be a non-negative integer smaller than the number of elements in the ring, otherwise an error is signaled.

*index* 0 returns or sets the element *object* just before the inser-

tion point, and a larger *index* goes "back" (in the same direction as `ring-pop` and `rotate-ring`).

The `setf` function replaces the element in the ring with the new element *object* without affecting the ring otherwise (in particular it does not call *delete-function*).

## rotate-ring

## *Function*

Summary      Rotates a ring, that is moves the insertion point.

Package      `hcl`

Signature      `rotate-ring ring how-many => object`

Arguments      `ring`      A ring object created by `make-ring`.  
                  `how-many`    A fixnum.

Values      `object`      A Lisp object.

Description      The function `rotate-ring` rotates the ring, that is it moves the insertion point "back", which is the same direction that `ring-pop` would progress.

*how-many* is the number of positions to rotate. It has to be a fixnum, but otherwise is not limited.

`rotate-ring` returns the element before the insertion point after the rotation (the one that (`ring-ref ring 0`) would return if called immediately after `rotate-ring`).

Examples      If the ring contains 3 elements or more, then

```
(progn
  (ring-pop ring)
  (ring-pop ring)
  (ring-ref ring 0))
```

returns the same value as:

```
(rotate-ring ring 2)
```

but the second form does not remove an element from the ring, while the first form removes 2 elements.

**safe-format-to-string**

**safe-format-to-limited-string**

**safe-prin1-to-string**

**safe-princ-to-string**

*Functions*

Summary      Print or format "safely", which means catching errors.

Package      **hcl**

Signature      **safe-format-to-string &rest format-args => string**  
**safe-format-to-limited-string limit &rest format-args => string**  
**safe-prin1-to-string object => string**  
**safe-princ-to-string object => string**

Arguments      **format-args**      A control-string and arguments as passed to **format**.

**limit**      A positive integer.

**object**      Any object.

| Values      | <code>string</code> | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description |                     | <p><code>safe-format-to-string</code>, <code>safe-prin1-to-string</code> and <code>safe-princ-to-string</code> are analogs to the standard functions <code>format</code> (with first argument <code>nil</code>), <code>prin1-to-string</code> and <code>princ-to-string</code>. If <i>format-args</i> and <i>object</i> can be printed without any errors then they are equivalent to the standard functions, except that they bind <code>*print-readably*</code> and <code>*print-circle*</code> to <code>nil</code>.</p> <p>The difference is when there is an error during the printing operation. The "safe" functions catch the error, and try to produce something that indicates that an error occurred during the printing operation and what it was, without causing recursive errors.</p> <p><code>safe-format-to-limited-string</code> is like <code>safe-format-to-string</code>, except that the length of the result <i>string</i> is limited to <i>limit</i>. The printing is stopped when the output become longer than <i>limit</i> and the result is a string of length <i>limit</i>, with the last three characters being "...". Limiting the length in this way also copes well when printing deeply nested objects.</p> |
| Notes       |                     | <p>These functions are intended to be used in code that handles and reports errors, where it is important to avoid recursive errors.</p> <p>The debugging tools of the LispWorks IDE use these functions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Values             | <i>realp</i> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description        | The function <code>save-argument-real-p</code> always returns <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                           |
| Compatibility note | In LispWorks 6.1 for Macintosh and earlier versions, <code>save-argument-real-p</code> can be used to determine whether a build script knows the real name of the image being saved. The return value <i>realp</i> is <code>nil</code> only when building an intermediate image for the purpose of building a universal binary.<br><br>In LispWorks 7.0 and later versions, universal binaries are not supported hence <code>save-argument-real-p</code> always returns <code>t</code> . |

| Values      | <i>path</i> | A pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description |             | <p>The function <code>save-current-profiler-tree</code> checks if <i>filename</i> has a type, and if not adds the type "<code>tree</code>". It then opens the file for writing with <code>:if-exists :supersede</code> and <code>:external-format :utf-8</code>, and writes the current profiler tree into it. <i>name</i> is written to the file as the name of the tree, using <code>format</code> with <code>~A</code>.</p> <p>The current profiler tree is set either when <code>profile</code> finishes successfully, or when <code>stop-profiling</code> is called with <code>nil</code> for its <i>suspend</i> argument (the default). There is only one current tree, and it is overwritten each time it is set.</p> <p>The intention of the file is that you can load it into the Profiler tool in the LispWorks IDE to view its contents. However, you can also parse it yourself, or view it as a text file for simple queries.</p> <p><i>name</i> should be useful for you to remember what the tree is about. For example, it may be something like the result of:</p> <pre>(string-append "Computing this and that at "                (date-string))</pre> <p>The Profiler tool displays <i>name</i> in the message area of the interface (at the bottom), and it is used in the <b>History</b> menu.</p> <p><code>save-current-profiler-tree</code> returns the path that was used.</p> <p>The format of the file is described in “Profiler tree file format” on page 174.</p> |

| Values                      | <code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description                 | <p>The function <code>save-current-session</code> closes all windows and stops multiprocessing, saves an image at the location supplied in <code>pathname</code>, and restarts multiprocessing and the windows. For more information see “Saved sessions” on page 182.</p> <p><code>save-image-args</code> are passed to the saving function, which is <code>save-image</code> on Windows, GTK and Motif, or <code>save-image-with-bundle</code> on Cocoa.</p> <p><code>save-current-session</code> returns <code>nil</code> if the pathname supplied is unacceptable (not writable), otherwise it returns <code>t</code>. The actual operation is done asynchronously.</p> |
| Notes                       | <ol style="list-style-type: none"> <li>1. <code>save-current-session</code> is intended for saving the state of a windowing image. While <code>save-current-session</code> can be used to save a session in a console image, this achieves nothing more than <code>save-image</code>.</li> <li>2. The released LispWorks image runs the default session. Therefore after you have used <code>save-current-session</code>, starting the supplied image (for example via the Windows start menu or Mac OS X Dock) will run itself only if the default session is "LispWorks Release".</li> </ol>                                                                              |

| <i>restart-function</i> | A function to be called on restart.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>multiprocessing</i>  | Controls whether multiprocessing is enabled on restart. Possible values are discussed below.                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>console</i>          | On Windows <i>console</i> controls whether the new image will be a Console or GUI application and when, if ever, to make a console window in the latter case.<br>On the Macintosh <i>console</i> controls when, if ever, to make a console window.<br>Possible values are discussed below.                                                                                                                                                                                   |
| <i>environment</i>      | <i>environment</i> controls whether the LispWorks environment is started on restart. Possible values are discussed below.                                                                                                                                                                                                                                                                                                                                                    |
| <i>remarks</i>          | <i>remarks</i> adds a comment to the save history. The value should be a string.                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>clean-down</i>       | When <i>t</i> , calls ( <code>clean-down t</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>image-type</i>       | One of the keywords : <code>exe</code> , : <code>dll</code> and : <code>bundle</code> .                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>split</i>            | A generalized boolean. If non-nil, the Lisp heap and the executable are saved in two separate files.                                                                                                                                                                                                                                                                                                                                                                         |
| Values                  | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description             | <p>The function <code>save-image</code> saves the LispWorks image to a new executable or dynamic library containing any modifications you have made to the supplied image.</p> <p>For information about the sort of changes you might want to save in a new image, see Chapter 13, “Customization of LispWorks”.</p> <p>Do not use <code>save-image</code> when the graphical IDE is running. Instead create a build script and use it with the <code>-build</code> com-</p> |

mand line argument similar to the examples below, or run LispWorks in a subprocess using the Application Builder tool.

You cannot use `save-image` on Windows, Linux, FreeBSD, AIX, x86/x64 Solaris and Mac OS X when multiprocessing is running. It signals an error in this case.

On Cocoa you can combine a call to `save-image` with the creation of an application bundle containing your new LispWorks image, as in the example shown below.

`dll-exports` is implemented only on Windows, Linux, x86/x64 Solaris, Macintosh and FreeBSD. It controls whether the image saved is an executable or a dynamic library (DLL). The default value is `:default` and this value means an executable is saved. The value `:com` is supported on Microsoft Windows only (see below). Otherwise `dll-exports` should be list (potentially `nil`). In this case a dynamic library is saved, and each string in `dll-exports` names a function which becomes an export of the dynamic library and should be defined as a Lisp function using `fli:define-foreign-callable`. Each exported name can be found by `GetProcAddress` (on Windows) or `dlsym` (on other platforms). The exported symbol is actually a stub which ensures that the LispWorks dynamic library has finished initializing, and then enters the Lisp code.

On Microsoft Windows the `dll-exports` list can also contain the keyword `:com`, or `dll-exports` can simply be the keyword `:com`, both of which mean that the DLL is intended to be used as a COM server. See the *LispWorks COM/Automation User Guide and Reference Manual* for details.

On Mac OS X the default behavior is to generate an object of type "Mach-O dynamically linked shared library" with file type `dylib`. See `image-type` below for information about creating another type of library on Mac OS X.

On Linux, Macintosh, x86/x64 Solaris and FreeBSD, to save a dynamic library image the computer needs to have a C compiler installed. This is typically `gcc` (which is available by installing Xcode on the Macintosh).

An image saved as a dynamic library (DLL):

- always runs multiprocessing, and
- may need to be shut down by `QuitLispWorks` or by a callback which uses `dll-quit`.

`automatic-init` specifies whether a LispWorks dynamic library should initialize inside the call to `LoadLibrary` (on Microsoft Windows) or `dlopen` (on other platforms), or wait for further calls. Automatic initialization is useful when the dynamic library does not communicate by function calls. On Microsoft Windows it also allows `LoadLibrary` to succeed or fail according to whether the LispWorks dynamic library initializes successfully or not. Not using automatic initialization allows you to relocate the library if necessary using `InitLispWorks`, and do any other initialization that may be required. The default value of `automatic-init` is `t` on Windows, `nil` on other platforms. For more information about automatic initialization in LispWorks dynamic libraries, see Chapter 14, “LispWorks as a dynamic library”.

`dll-added-files` should be a list of filenames. It is ignored on Microsoft Windows. On other platforms if `dll-added-files` is non-nil then a dynamic library containing each named file is saved. Each file must be of a format that the default C compiler (`scm:*c-default-compiler*`) knows about and can incorporate into a shared library. Typically they will be C source files, but can also be assembler or object files. They must not contain exports that clash with names in the LispWorks dynamic library (see Chapter 54, “Dynamic library C functions” for the predefined exports). The added files are useful to write wrappers around calls into the LispWorks dynamic library. Such wrappers are useful for:

- Calling `InitLispWorks` when required, for example to relocate the LispWorks dynamic library to avoid memory clashes with other software, as described under “Startup relocation” on page 459.
- Calling `QuitLispWorks` when required.
- Changing calls that involve complex C structs or even C++ objects into plain calls, because accessing C structures in Lisp requires defining the structure, while in C it only needs to include the header.
- Creating 'stub' functions that can be called from Lisp, for example for calling a C++ method. The address of the stub function can be passed to Lisp which can call it using a function defined by `fli:define-foreign-funcallable`.
- Adding code that runs automatically inside the call to `dlopen`, by using `__attribute__ ((constructor))`

*dll-extra-link-options* should be a list of strings. It is ignored on Microsoft Windows. On other platforms if *dll-extra-link-options* is non-nil then the strings are passed as extra command line arguments to the linker. See the documentation for the linker (typically called `ld`) for the operating system you are using for the meaning of these arguments. On Macintosh, a default value for the `-install_name` option is generated using the file-namestring of the dynamic library if "`-install_name`" is not specified in *dll-extra-link-options*.

*image-type* defaults to `:exe` or `:dll` according to the value of *dll-exports* and therefore you do not normally need to supply *image-type*.

*image-type :bundle* is used only when saving a dynamic library. On Mac OS X it generates an object of type "Mach-O bundle" and is used for creating shared libraries that will be used by applications that cannot load dylibs (FileMaker for example). It also does not force the filename extension to be `.dylib`. On other Unix-like systems *image-type* merely has the

effect of not forcing the file type of the saved image, and the format of the saved image is the same as the default. On Microsoft Windows *image-type :bundle* is ignored.

**Note:** *image-type :bundle* is completely unrelated to the Mac OS X notion of an application bundle.

If *split* is `nil` (the default), then the saved image is written as a single executable file containing the Lisp heap. If *split* is `t`, then the saved Lisp heap is split into a separate file, named by adding `.lheap` to the name of the executable. When the executable runs, it reloads the Lisp heap from this file automatically.

In addition, when saving LispWorks on the Macintosh as an application bundle (for example by using `create-macos-application-bundle`) or as a framework bundle, *split* can be the symbol `:resources`. This places the Lisp heap file in the `Resources` directory of the bundle, which allows the heap to be included in the bundle's signature. For an application bundle, the `Resources` directory is in the `Contents` directory alongside the `MacOS` directory. For a framework bundle, the `Resources` directory is alongside the shared library. The executable and Lisp heap file must be in these directories within the bundle at run time.

The main use of *split* is to allow third-party code signing to be applied to the executable, which is often not possible when saving an image with the Lisp heap included in a single file.

*restart-function*, if non-`nil`, specifies a function (with no arguments) to be called when the image is started. If *multiprocessing* is true, *restart-function* is called in a new process. *restart-function* is called after the initialization file is loaded. The default value of *restart-function* is `nil`.

**Note:** *restart-function* is not called if the command line argument `-no-restart-function` is present

When *multiprocessing* is `nil`, the executable image will start without multiprocessing enabled. When *multiprocessing* is

true or the image is a DLL, the image will start with multiprocessing enabled, starting processes in the list `*initial-processes*`. When `*initial-processes*` is `nil` or `multiprocessing` is `:with-tty-listener`, a TTY listener process is started as well. The default value of `multiprocessing` is `nil`.

`console` is implemented only in LispWorks for Windows and LispWorks for Macintosh. The possible values for `console` are as follows:

- `:default` Unchanged since previous save.
- `t` On the Macintosh, the value `t` has the same effect as the value `:always`.  
On Windows, a Console application is saved, else a Windows application is saved which creates its own console according to the other possible values.
- `:input, :output, :io` Whenever input, output or any I/O is attempted on `*terminal-io*`.
- `:init` At startup, if input and output are not redirected
- `:always` At startup, even if input and output are redirected.

The LispWorks for Windows and LispWorks for Macintosh images shipped have `console` set to `:input`.

The possible values for `environment` are as follows:

- `:default` Unchanged since previous save.
- `nil` Start with just the TTY listener.
- `t` Start the environment automatically, no TTY listener.

**:with-tty-listener**

Start the environment automatically, but still have a TTY listener.

The LispWorks image shipped is saved with `:environment t` on all platforms except for the Motif images on Mac OS X, and SPARC Solaris

You should not try to save a new image over an existing one. Always save images using a unique image name, and then, if necessary, replace the new image with the old one after the call to `save-image` has returned.

**Notes** 1. Do not supply `:multiprocessing nil` along with a true value of `:environment t`. Multiprocessing is needed for the GUI environment.

2. `load-image` checks that `load-all-patches` has been called. If it is called before `load-all-patches` in a session then an error is signaled.
3. In the example build scripts below, the call to `load-all-patches` is not strictly required when the script is used with the `-build` command line argument, because LispWorks 6.1 and later versions call `load-all-patches` automatically. However, it does no harm for the build script to call `load-all-patches` too.

**Compatibility notes** 1. LispWorks 5.0 and previous versions documented `-init` as the way to run LispWorks with a build script. This way is deprecated.

2. Note that LispWorks quits automatically after processing a build script via `-build`, whereas with `-init` you need to call `quit` explicitly at the end of the build script.
3. In LispWorks 5.0 and previous versions `dll-exports` is supported only on Windows.
4. `dll-added-files` and `automatic-init` were new in LispWorks 5.1.

**Example** Here is an example build script. Save this to a file such as `c:/build-my-image.lisp`:

```
(load-all-patches)
(load "my-code")
(save-image "my-image")
```

Then run LispWorks with the command line argument `-build c:/build-my-image.lisp` to save the image `my-image.exe`.

This example shows a portable build script which, on Cocoa, saves your new LispWorks image in a Mac OS X application bundle. This allows your new LispWorks for Macintosh image to be launchable from the Finder or Dock and to have its own icon or other resources:

```
(load-all-patches)
(load "my-code")
#+:cocoa
(compile-file-if-needed
 (example-file
  "configuration/macos-application-bundle")
 :load t)
(save-image
 #+:cocoa
 (write-macos-application-bundle
  "/Applications/LispWorks 7.1/My LispWorks.app")
 #:-:cocoa
 "my-lispworks")
```

| Summary     | Saves a LispWorks for Macintosh image with an application bundle, thus allowing it to work properly in the Cocoa windowing system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Description | <p>The function <code>save-image-with-bundle</code> first creates the application bundle using the function <i>bundle-function</i>, and then saves the LispWorks image in the bundle.</p> <p>The default value of <i>bundle-arguments</i> is <code>nil</code>.</p> <p>The default value of <i>bundle-function</i> is <code>create-macos-application-bundle</code>. You can modify the created bundle by supplying <i>bundle-arguments</i>.</p> <p>With the default values of <i>bundle-function</i> and <i>bundle-arguments</i>, it copies the application bundle of the running image to the bundle path with the minimal necessary modifications, and then saves an image in it.</p> <p><code>save-image-with-bundle</code> operates as follows:</p> <ol style="list-style-type: none"> <li>1. It calls <i>bundle-function</i> with the <i>bundle-path</i> and <i>bundle-arguments</i>, and then uses the result as the <i>filename</i> for <code>save-image</code>.</li> </ol> |

- It applies `save-image` to the path derived in the first step and the remaining arguments passed to `save-image-with-bundle` (other than *bundle-arguments* and *bundle-function*).

Notes      `save-image-with-bundle` is implemented only in Lisp-Works for Macintosh.

## **save-universal-from-script** *Function*

Summary     Deprecated. Signals an error.

Package     `hcl`

Signature    `save-universal-from-script target-image script-name &key output-stream => target-image`

Arguments    `target-image`    A pathname designator.  
`script-name`    A pathname designator.  
`output-stream`    A stream or `nil`.

Values       `target-image`    A pathname designator.

Description    The function `save-universal-from-script` is deprecated

Compatibility note    In LispWorks 6.1 for Macintosh and earlier versions, `save-universal-from-script` provides a convenient way to create a universal binary on an Intel Macintosh, using a script designed for saving a mono-architecture image.

LispWorks 7.0 and later versions do not support universal binaries, hence `save-universal-from-script` now simply signals an error.

**set-array-single-thread-p** *Function*

Summary Tells the system whether an array is accessed only in a single thread context, or not.

Package `hcl`

Signature `set-array-single-thread-p array on-p`

Arguments `array` An array.

`on-p` A generalized boolean.

Description Tells the system whether the array *array* is accessed only in a single thread context or not, depending on the value of *on-p*. Arrays that are marked for single thread access are faster for some operations, in particular `vector-push` and `vector-pop`.

`make-array`

**set-array-weak** *Function*

Summary Sets the weakness state of an array.

| Description        | <p>By default, arrays are non-weak, and they keep alive all the objects that are stored in them. A weak array may remove a pointer if the object that it points to is not pointed to from somewhere else. When a pointer is removed like this, it is replaced in <code>array</code> with <code>nil</code>.</p> <p>Pointers are replaced by <code>nil</code> after a garbage collector (GC) operation that identifies that they can be replaced. This means that if the object that is pointed to has been promoted to a higher generation, a garbage collection of the higher generation is required to remove the pointer. Note that by default the system does not automatically GC the blocking generation or higher.</p> <p>The weakness state of an array can be changed many times.</p> <p>In all implementations, <code>array</code> must not be a displaced array, and the <code>array-element-type</code> of <code>array</code> must be <code>t</code>.</p> <p>In 64-bit LispWorks, an additional requirement is that <code>array</code> must be an adjustable array.</p> <p><code>set-array-weak</code> can be called at any moment.</p> |                    |                                                                    |                    |                                                                                                                                      |
| Notes              | An array can be made weak at creation time using the <code>:weak</code> argument to <code>make-array</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                    |                    |                                                                                                                                      |

## **set-default-generation** Function

|             |                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Set the current generation for memory allocation in 32-bit LispWorks.                                                                                             |
| Package     | <code>hcl</code>                                                                                                                                                  |
| Signature   | <code>set-default-generation num =&gt; num</code>                                                                                                                 |
| Arguments   | <code>num</code> The number of the generation from which to do future allocation.                                                                                 |
| Values      | Returns <code>num</code> .                                                                                                                                        |
| Description | Set the current generation for memory allocation. By default the system allocates memory from the youngest generation (generation 0).                             |
| Notes       | <code>set-default-generation</code> is useful only in 32-bit LispWorks. In 64-bit implementations it does nothing and returns 0.                                  |
| Examples    | <pre>(set-default-generation 1) ;; allocate from an ;; older generation (set-default-generation 0) ;; return to normal</pre>                                      |

## set-gc-parameters *Function*

**Summary** Sets the parameters for the garbage collector in 32-bit LispWorks. This function is deprecated.

**Package** `hcl`

**Signature** `set-gc-parameters &key maximum-buffer-size minimum-buffer-size big-object promote-min-buffer promote-max-buffer new-generation-size minimum-overflow maximum-overflow minimum-for-sweep minimum-for-promote enlarge-by-segments => <no values>`

**Arguments** Unless stated, arguments are in bytes:

***maximum-buffer-size***

Maximum size of the small objects buffer.

***minimum-buffer-size***

Minimum size of the small objects buffer.

***big-object*** An object that is bigger than this value is “big”. That is, it is not allocated from the small objects buffer, but from the big-chunk area (if it is allocated in generation 0 in the normal way).

***promote-min-buffer***

During promotion, a buffer is allocated in the generation being promoted into, and the objects promoted are moved into it. *promote-min-buffer* controls the minimum size of this buffer.

*promote-max-buffer*

Controls the maximum size of the promotion buffer.

*new-generation-size*

Controls the minimum enlargement of generation *gen-num*, for *gen-num* > 0. Value 0 means the generation is not expanded. Otherwise, *new-generation-size* must be a fixnum in the exclusive range (10000, 100000000) and the minimum expansion is then *new-generation-size* \* *gen-num* words.  
*new-generation-size* has no effect on the enlargement of generation 0.

*maximum-overflow*

Maximum size of the small-objects buffer in the big-chunk area.

*minimum-overflow*

Minimum size of the small-objects buffer in the big-chunk area.

*minimum-for-promote*

Controls the frequency of promotions. Setting *minimum-for-promote* to a high value causes the system to promote less frequently. This may improve performance for programs that allocate a lot of data for a short term and then delete it.

*minimum-for-sweep*

Controls when a mark and sweep takes place. Setting *minimum-for-sweep* to a high value causes the system to mark and sweep less often, which means it has to grow. The

CPU time spent in garbage collection is mostly smaller, but the process is bigger and may cause more disk access.

*enlarge-by-segments*

A minimum for how much the image grows each time a segment is enlarged, as a multiple of 64 KB. This parameter is ignored when adding a static segment.

|             |                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | None.                                                                                                                                              |
| Description | This function sets the parameters of the garbage collector, using the keywords described above.                                                    |
| Notes       | <code>set-gc-parameters</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations. |
| See also    | <code>get-gc-parameters</code><br>“Memory Management in 32-bit LispWorks” on page 135                                                              |

|                      | <p><b>:key</b> — An entry is kept if there is a pointer to the key from another object.</p> <p><b>:both</b> — An entry is kept if there are pointers to both the key and the value.</p> <p><b>:one or :either</b> — An entry is kept if there is a pointer to either the key or the value.</p> <p><b>nil</b> — Make the hash-table non-weak. All entries are kept.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>free-function</i> | A designator for a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values               | Returns <i>weak</i> , unless <i>t</i> was passed, when <b>:value</b> is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description          | <p>By default, hash-tables are not weak, which means that they keep alive all the keys and the values in the table.</p> <p>A weak hash-table allows entries to be removed if there are no other pointers to them. The <i>weakness-state</i> tells the system which entries may be removed like this.</p> <p>Entries that can be removed are removed after a garbage collector (GC) operation which identifies that they can be removed. This means that if the relevant object(s) (the key or the value) have been promoted to a higher generation, a garbage collection (GC) of the higher generation is required to remove them from the table. Note that by default the system does not automatically GC the blocking generation or higher.</p> <p>The <i>weakness-state</i> of a hash-table can be changed repeatedly, at any time, at any point using any of the <i>weak</i> values listed above. It can also be set by <b>make-hash-table</b>.</p> <p><i>free-function</i> can be supplied to specify a free function as described for <b>make-hash-table</b>. It has no effect if <i>weak-kind</i> is <b>nil</b>.</p> |

## set-minimum-free-space *Function*

|             |                                                                                                                                                                                                                                                                    |  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Sets the minimum free space for a segment of the specified generation in 32-bit LispWorks.                                                                                                                                                                         |  |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                   |  |
| Signature   | <code>set-minimum-free-space gen-num size &amp;optional segment =&gt; generation-size</code>                                                                                                                                                                       |  |
| Arguments   | <code>gen-num</code> The generation to be affected.<br><code>size</code> The size (in bytes) to set the segment to.<br><code>segment</code> An integer specifying the segment to be affected. The default value is 0, meaning the first segment of the generation. |  |
| Values      | <code>generation-size</code> A list showing information for the generation just specified in the call.                                                                                                                                                             |  |
| Description | Sets the minimum free space for a segment of the specified generation.<br><br>By default, affects the first segment — pass <code>segment</code> to affect a different segment of the generation.<br><br>The minimum free space is shown by <code>room</code> .     |  |
| Notes       | <code>set-minimum-free-space</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations.                                                                                                            |  |

| <i>processes</i> controls which processes are added to the set, removed from the set or are contained in the set, as follows: |                                                                                                                                                                                                                                                                                                                                                  |
| <code>:current</code>                                                                                                         | Means the current process. When <code>start-profiling</code> is called it interprets <code>:current</code> to mean the current process at the time it is called. If <code>set-process-profiling</code> is called while profiling, <code>:current</code> is interpreted as the current process when <code>set-process-profiling</code> is called. |
| <code>:all</code>                                                                                                             | Means all processes, including those which are created after profiling started.                                                                                                                                                                                                                                                                  |
| <code>:new</code>                                                                                                             | All processes created after the call to <code>start-profiling</code> , unless <code>set-process-profiling</code> is called while profiling, in which case it is any process created after this call.                                                                                                                                             |

#### A `mp:process` object

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | Means that process.                                                                                                                                       |
| A list | Means the processes in that list. The list can contain the symbols <code>:current</code> or <code>:new</code> , which are interpreted as described above. |

`set-process-profiling` can be called whether or not the profiler is collecting information. See `start-profiling` and `stop-profiling`.

Note: This function only works on platforms in SMP LispWorks ; in non-SMP LispWorks, all processes are profiled.

#### Examples

Add *process1* to the set:

```
(set-process-profiling :add process1)
```

Turn off profiling for the current process:

```
(set-process-profiling :remove :current)
```

Turn off all profiling:

```
(set-process-profiling :remove :all)
```

Set all processes for later profiling:

```
(set-process-profiling :set :all)
```

## **set-profiler-threshold** *Function*

**Summary** Sets the percentage threshold for symbols to be profiled in a subsequent run.

**Package** `hcl`

**Signature** `set-profiler-threshold value => value`

**Arguments** `value` must be a fixnum between 0 and 100.

**Values** `set-profiler-threshold` returns `value`.

**Description** This function sets the value of `*profiler-threshold*` below which symbols are not profiled in a repeated profiling run. After a profiling run, all the symbols being profiled have a percentage value for the amount of time they were on the top of the stack. If `*profiler-threshold*` is set to 40 then by running `reset-profiler` with argument `:top` all symbols which are found on the top of the stack less than forty percent of the time are removed from the list of those symbols considered for profiling.

Example      `(set-profiler-threshold 40)`

## set-promotion-count                          *Function*

Summary      Controls when objects can be promoted to the next generation in 32-bit LispWorks. This function is deprecated.

Package      `hcl`

Signature     `set-promotion-count gen-num count &optional segment => count`

Arguments    `gen-num`      The generation number affected.

`count`      The number of garbage collections survived by objects in that generation, before promotion. If `count` is `nil`, the function returns the current promotion count setting.

`segment`     An integer specifying which segment of the generation is to be affected. The default is 0, meaning the lowest segment of the generation.

Values       Returns `count`.

Description    Controls how many garbage collections an object in a segment must survive before promotion to the next generation.

Notes        1. `set-promotion-count` is deprecated, because experience has shown that it is not useful.

2. `set-promotion-count` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, wherein you may be able to achieve the effect with `set-delay-promotion`.

| Description |                                                                                          | The function <code>set-system-message-log</code> manipulates the system message log. This log is used by the system to produce messages that indicate that something is not as expected, but is not an error. For example, putting a bad Break-Gesture in a GTK resource file. |

If *stream* is `t` or a stream, the system message log stream is set, with `t` meaning `*standard-output*`. This stream is used when writing messages.

When *collect* is true but not `:no-change`, messages are collected in an internal list, which can be retrieved by using *get*.

*callback* can be a designator for a function of one argument, a string. This function is called when a message is generated. The callback must not try to perform GUI operations.

The default value of each of *stream*, *collect* and *callback* is `:no-change`, which does not change the current setting.

When *get* is supplied `set-system-message-log` returns a list of the messages that has been collected. Each message is a single string. If *get* is `t`, the internal list is reset to `nil`. If *get* is `:keep`, the internal list is not reset, so the next call with *get* will get them again.

`set-system-message-log` returns `nil` if *get* is not supplied.

`set-system-message-log` returns the list of collected messages if *get* is supplied.

**Notes** *stream*, *callback* and *collect* are mutually independent. It is possible to set the system to any combination of these.

The order of operation when a message is generated is first to print, then call the callback, and then collect.

When collecting messages it can accumulate, so it is important to periodically get the message to ensure it does not bloat the memory.

Using *collect* `t` when it is already collecting has no effect, in particular it does not affect the list of collected messages.

## set-up-profiler

## *Function*

**Summary** Declares the parameter values of the profiling function.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Values      | The time interval is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description | <p><code>set-up-profiler</code> is used to declare the values of the parameters of the profiling function.</p> <p><code>packages</code> specifies that the symbols in these packages should be monitored, that is added to <code>*profile-symbol-list*</code>. If <code>packages</code> is <code>:all</code>, then symbols in all packages are monitored. If <code>packages</code> is <code>:none</code>, then no package is used to find symbols</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

to monitor. Otherwise, *packages* should be a list of package specifiers, and the symbols in these packages are monitored.

If *symbols* is non-nil, it should be a list of function-dspecs to monitor in addition to the symbols that were specified by *packages*. These are typically symbols, but can be other functions as specified in “Function dspecs” on page 84.

Note: When a symbol that names a generic function should be monitored, LispWorks adds all the methods of the generic function to the profile list.

If both *packages* and *symbols* are nil, then `set-up-profiler` behaves as if *packages* is :all. Thus if you actually want to monitor no symbols, you need to pass :*packages* :none. That is useful if you want to monitor only KnowledgeWorks rules (see *kw-contexts* below).

*kind* specifies the way that the time between samples is measured on Unix-like platforms:

- `:profile`      Process time only.
- `:virtual`      Process time and system time for the process.
- `:real`          Real time.

The default value of *kind* is `:profile`.

**Note:** *kind* is ignored on Microsoft Windows platforms.

*interval* specifies the interval in microseconds between profile samples. The minimum value of *interval* is 10000, that is 10 ms. The default value of *interval* is 10000.

*limit*, when non-nil, sets `*default-profiler-limit*`. This limits the maximum number of lines printed in the profile output (not including the tree). The default value is 100.

*cutoff*, when non-nil, sets `*default-profiler-cutoff*`. This is the default minimum percentage that the profiler will display in the output tree. Functions below this percentage

will not be displayed. The default is `nil`, that is there is no cutoff.

*collapse* specifies whether functions with only one callee in the profile tree should be collapsed, that is, only the child is printed. When passed, sets `*default-profiler-collapse*`. The default value of *collapse* is `nil`.

*style* controls the format of output. If *style* is not passed or passed as `nil`, the format does not change. If *style* is passed, it can take these values:

- |                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>:list</code> | The profiler will show the functions seen on the stack.                                                              |
| <code>:tree</code> | The profiler will generate a tree of calls seen in the profiler, as well as the output shown by <code>:list</code> . |

The default value of *style* is `:tree`.

*gc* specifies whether to profile functions inside the memory management code (more accurately, functions that are called on the GC stack) in addition to any other profiling. The default value of *gc* is `nil`.

*call-counter* specifies whether to add extra code to count calls. The counting is done dynamically. If *call-counter* is `nil`, call counters are not added, and the call counter of all functions is displayed as 0. The default value of *call-counter* is `nil` in SMP LispWorks and `t` in non-SMP LispWorks. This is because the counting significantly affects the performance of applications using Symmetric Multiprocessing (SMP).

*show-unknown-frames* controls whether the profile tree shows nodes where the name of the function is unknown. The default value of *show-unknown-frames* is `nil`.

*kw-contexts* allows you to profile forward chaining rules in KnowledgeWorks (see the *KnowledgeWorks and Prolog User Guide*). When *kw-contexts* is `t` (the default), all context are pro-

filed. Otherwise it should be a list of context names. The profiler profiles all the forward rules in each context.

*subfunctions* controls whether to profile subfunctions of the functions that are profiled. When it is non-nil, for each function that the profiler is profiling, the profiler checks if it has subfunctions, and if it has then it profiles them too. The default value of *subfunctions* is nil.

If *subfunctions* is non-nil then initializing the profiler is somewhat slower, and also, because the names of subfunctions are long, the output is more messy. It is sometimes useful though.

#### Notes

1. If the profiler is invoked before any call to `set-up-profiler`, it calls `set-up-profiler` implicitly without any arguments. That means it will monitor all symbols in the image, and if KnowledgeWorks is loaded also all forward chaining rules. In most cases this is a useful behavior, so it is not necessary to use `set-up-profiler`.
2. `set-up-profiler` finds all the symbols in the specified packages at the time it is called. Thus symbols that are given function definitions after the call to `set-up-profiler` are not profiled, whether or not they are in packages that were passed to `set-up-profiler`. If you want to ensure that all symbols are profiled, you need to call `set-up-profiler` just before invoking the profiler.
3. Call counting can affect performance significantly on some platforms. To get accurate timing (in scales of a few percentage points), pass *call-counter* nil. However, in most cases the profiler is used to find bottlenecks where the slowdown is hundreds of percentage points and so the effect of call counting is less significant.

4. *call-counter* is effective only on x86 platforms or in 64-bit LispWorks. On non-x86 platforms 32-bit LispWorks does call counting for a given function if the compiler optimize quality *debug* is greater than 0 at compile-time, and *call-counter* has no effect.
5. *limit*, *cutoff* and *collapse* affect only the display of the results, not the collection of profiler data.

Examples

```
(set-up-profiler :packages '(my-package common-lisp))

(set-up-profiler :symbols
                  (my-list-all-interesting-functions))
```

| Description |                 | The function <code>sets-who</code> returns a list of the special variables set by the definition named by <i>function</i> . |

Notes        The cross-referencing information used by `sets-who` is generated when code is compiled with source-level debugging switched on.

## **source-debugging-on-p**                          *Function*

Summary      Tests if source level debugging is on for compiled code.

Package       `hcl`

Signature      `source-debugging-on-p => bool`

Arguments     None.

Values        `bool`                          If `t`, source level debugging is on.

Description     Returns `t` if source level debugging is on for compiled code; otherwise returns `nil`.

| Arguments   | <code>initialize</code> A generalized boolean.<br><code>reset</code> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description | <p>The functions <code>start-gc-timing</code>, <code>stop-gc-timing</code> and <code>get-gc-timing</code> time Garbage Collector (GC) operations.</p> <p><code>start-gc-timing</code> causes the system to start collecting GC timing. If <code>initialize</code> is non-nil, <code>start-gc-timing</code> also resets the Garbage Collector times to 0. The default value of <code>initialize</code> is <code>t</code>.</p> <p><code>stop-gc-timing</code> stops collecting GC timing, but does not affect the times.</p> <p><code>get-gc-timing</code> returns the GC timing as a plist of the form</p> <pre>(:total total :user user :system system)</pre> <p>where <code>total</code>, <code>user</code> and <code>system</code> are real numbers giving the total, user and system times in seconds spent inside the Garbage Collector while GC timing is on since the timing was last reset. When <code>reset</code> is non-nil, <code>get-gc-timing</code> also switches GC timing off and resets the timing to 0. The default value of <code>reset</code> is <code>nil</code>.</p> <p>The GC timing is the same timing that is collected by <code>extended-time</code>. Once <code>start-gc-timing</code> is called, <code>extended-time</code> does not try to collect GC timing and print it until <code>get-gc-timing</code> is called with <code>reset</code> non-nil.</p> <p><code>get-gc-timing</code> can be called while GC timing is being collected.</p> |
| Notes       | <code>stop-gc-timing</code> and <code>start-gc-timing</code> (with <code>initialize = nil</code> ) can be used to collect GC timing only in specific periods without resetting the times. However the points at which the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Garbage Collector is invoked are not well-defined, so the program may allocate while GC timing is on, and spend time Garbage Collecting after you stopped collecting.

|           | <i>ignore-in-foreign</i>                                                                    | A boolean.                                                                                                                 |
|           | <i>time</i>                                                                                 | <code>t</code> , <code>nil</code> or <code>:extended</code> .                                                              |

Description      The function **start-profiling** starts collecting profiling information.

If *initialize* is non-nil any profiling information collected so far is discarded. The default value of *initialize* is `t`.

If *processes* is supplied, the set of processes that will be profiled is set as if by calling:

```
(set-process-profiling :set :processes processes)
```

Otherwise, the set of processes remains unchanged, so is controlled by any previous calls to **set-process-profiling**.

*processes* only works in SMP LispWorks. In non-SMP LispWorks, all processes are profiled.

*profile-waiting* is used only in SMP LispWorks. When *profile-waiting* is true, processes that are marked for profiling are profiled even if they are in a wait state. In non-SMP LispWorks, only processes that are active are profiled.

*ignore-in-foreign* controls whether to ignore processes that are inside foreign calls. The default value of *ignore-in-foreign* is *nil*.

*time* controls whether to output overall timing information with the profiler output. If *time* is *nil* then no timing information is output. If *time* is *t* (the default), then output like *time* is printed. If *time* is *:extended*, output like *extended-time* is printed. The output is done when *stop-profiling* is called with *print* and *suspend nil*, which are the defaults.

*start-profiling* can be repeatedly called without intervening calls to *stop-profiling*, for example to change the setting of *profile-waiting* or the profiled processes.

*start-profiling* cannot be used while *profile* is used or while the Profiler tool is profiling (on any thread). Between the call to *start-profiling* and the next call to *stop-profiling* with *print t* (or omitted), *profile* and the Profiler tool cannot be used.

Various parameters which are set by *set-up-profiler* control the behavior of the profiler. See the documentation for *set-up-profiler*.

If *start-profiling* is called before any call to *set-up-profiler*, it implicitly calls *set-up-profiler* without arguments, which will cause it to monitor all fbound symbols in the image.

## Examples

The following sequence of calls to *start-profiling* and *stop-profiling* can be used to profile only interesting work and print the results:

Start profiling the current process:

```
(start-profiling :processes :current)
(do-interesting-work)
```

Temporarily suspend profiling:

```
(stop-profiling :print nil)
(do-uninteresting-work)
```

Resume profiling:

```
(start-profiling :initialize nil)
(do-more-interesting-work)
(stop-profiling)
```

## string-trim-whitespace

*Function*

Summary      Trims whitespace characters from the beginning and end of a string.

Package      `hcl`

Signature      `string-trim-whitespace string => trimmed-string`

Arguments      `string`      A string.

Values      `trimmed-string`      A string.

Description      The function `string-trim-whitespace` returns a substring of `string`, with all whitespace characters stripped off the

beginning and end. A whitespace character is a character for which `whitespace-char-p` returns `t`.

See also `whitespace-char-p`  
`cl:string-trim`

## **stop-profiling** *Function*

Summary Stops collecting profiling information.

Package `hcl`

Signature `stop-profiling &key print stream`

Arguments `print` A generalized boolean.

`stream` An output stream.

`suspend` A generalized boolean.

Description The function `stop-profiling` stops collecting profiling information, and optionally prints the results.

If `suspend` is false, then the next call to `start-profiling` must pass `initialize t` or omit the `initialize` argument. In addition, if `print` is true, then the collected profiler information is printed.

If `suspend` is true, then the profiler is put into a suspended state where no profiling information is collected, but can be restarted by calling

```
(start-profiling :initialize nil)
```

The default value of `print` is `t` and the default value of `suspend` is (not `print`). The value of `print` is ignored if `suspend` is true.

`stream` specifies the stream for output when `print` is non-nil. It is ignored when `print` is `nil`. The default value of `stream` is the value of `*trace-output*`.

| Arguments   | <i>function</i> A function of one argument, the object.<br><i>gen-0</i> A generalized boolean, default value <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Values      | <code>sweep-all-objects</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
| Description | <p>Applies <i>function</i> to all the live objects in the image. Normally it is not useful to sweep objects in generation 0 because they are ephemeral, so by default <code>sweep-all-objects</code> does not sweep generation 0. This can be changed by passing a non-nil value as <i>gen-0</i>.</p> <p><i>function</i> should take one argument, the object. It can allocate, but if it allocates heavily the sweeping becomes unreliable. Small amounts of allocation will normally happen only in generation 0, and so will not affect sweeping of other generations.</p> |  |

To call `sweep-all-objects` reliably, do it inside `with-other-threads-disabled`.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | In 64-bit LispWorks and in the Mobile GC there is a more specific alternative: function <code>sweep-gen-num-objects</code> can be used to call a function on all live objects in a particular generation.<br><br>In the Mobile GC, <code>sweep-all-objects</code> does not sweep <code>cons</code> objects. There is also a more specific alternative: function <code>mobile-gc-sweep-objects</code> can be used to call a function on all live objects in particular generations. |

## \*symbol-alloc-gen-num\*

## **Variable**

**Summary** Specifies the generation in which interned symbols and their symbol names are allocated.

## Package hcl

Initial value 2 in 32-bit LispWorks, 3 in 64-bit LispWorks

See also [allocation-in-gen-num](#)

## symbol-dynamically-bound-p

## *Function*

**Summary** The predicate for whether a symbol is dynamically bound.

## Package hcl

Signature `symbol-dynamically-bound-p symbol => result`

Arguments      *symbol*      A non-nil symbol.

Values              *result*              A boolean.

**Description** The function `symbol-dynamically-bound-p` is the predicate for whether the symbol `symbol` is dynamically bound in the current environment.

|             | <code>result-form</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A Lisp form. |
| Description | <p>The macro <code>throw-if-tag-found</code> checks whether it can find the catch tag <code>catch-tag</code> by using <code>find-throw-tag</code>. If it finds <code>catch-tag</code> it throws to <code>catch-tag</code> the value(s) of evaluating <code>result-form</code>. Otherwise <code>throw-if-tag-found</code> returns <code>nil</code>, without evaluating <code>result-form</code>.</p> <p>The throwing operation is done by a normal throw. Therefore the only the difference between this and <code>c1:throw</code> is when the tag is not found. In this case, <code>c1:throw</code> would evaluate the result form and then give an error, but <code>throw-if-tag-found</code> simply returns nil.</p> |              |

|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>on</i>   | Flag ( <code>t</code> or <code>nil</code> ) to control the resulting setting of the variables. The default is <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | <i>bool</i> | The current state of source level debugging:<br><code>t</code> if source level debugging is on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |             | <p><code>toggle-source-debugging</code> sets certain compiler parameters, and also turns leaf case optimizations on (when called with <code>nil</code>) or off (when called with <code>t</code>). For all these parameters, the value <code>nil</code> reduces compilation speed.</p> <p><code>toggle-source-debugging</code> is called in the configuration file <code>a-dot-lispworks.lisp</code>, and the initial state of LispWorks such that source level debugging is on.</p> <p>The parameters relate to information required for source level debugging, cross-referencing and finding all changed definitions.</p> <p>The parameters (all in the <code>compiler</code> package) are:</p> |

**\*produce-xref-info\***

When true, the compiler produces information for the Cross Referencer.

**\*load-xref-info\***

When true, the cross-referencing information produced by the compiler is loaded when the corresponding file is loaded.

**\*notice-changed-definitions\***

When true, the Cross Referencer notices when a function is redefined, including an interpreted redefinition..

**\*source-level-debugging\***

When true, the compiler generates information used by the debugger.

`toggle-source-debugging` modifies the status of the variables, and then returns the new value. To check whether all the variables are set to true, without modifying them, use `source-debugging-on-p`.

Cross-referencing information is used by the functions `who-calls`, `who-binds`, `who-references`, `who-sets`, and friends.

Compatibility notes In LispWorks 4.2 and earlier, `toggle-source-debugging` controlled source file recording information. In LispWorks 4.3 and later, this is controlled independently by `*record-source-files*`.

## **total-allocation** *Function*

Summary Calculate memory consumed since the image was started.

Package `hcl`

Signature `total-allocation`

Arguments None.

Values Returns the amount allocated

Description This function calculates the total amount of memory consumed since the current image was created. Use at the start and end of a piece of code, to see how much it allocates.

| Summary       | The list of arguments given to the function being traced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description   | Upon entering a function that is being traced, <code>*traced-arglist*</code> is bound to the list of arguments given to the function. <code>*traced-arglist*</code> is then printed after the function name in the output from tracing. It is accessible in the <code>:before</code> and <code>:after</code> forms to <code>trace</code> . However care should be used when manipulating this variable, since it is the value of <code>*traced-arglist*</code> itself that is used when calling the traced function. Thus if this value is altered by the <code>:before</code> forms then the function receives the altered argument list. |
| Example       | <pre>USER 14 &gt; (trace (+ :before                       ((setq *traced-arglist*                            (mapcar #'1+                                    *traced-arglist*))))) + USER 15 &gt; (+ 1 2 3) 0 + &gt; (1 2 3)           (2 3 4) 0 + &lt; (9) 9</pre>                                                                                                                                                                                                                                                                                                                                                                        |
| Notes         | <code>*traced-arglist*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>*trace-indent-width*</b> |  | <i>Variable</i>                                                                |
|-----------------------------|--|--------------------------------------------------------------------------------|
| Summary                     |  | The amount of extra indentation in the trace output for each level of nesting. |
| Package                     |  | <code>hcl</code>                                                               |
| Initial value               |  | 2                                                                              |

Description      **\*trace-indent-width\*** is the extra amount by which the traced output for function calls is indented upon entering a deeper level of nesting (that is, a traced call from a function that is itself traced). If it is 0 then no indentation occurs.

Example

```
CL-USER 1 > (setq *trace-indent-width* 4
                     *max-trace-indent* 50)
50

CL-USER 2 > (defun quad (a b c) (- (* b b) (* 4 a c)))
QUAD

CL-USER 3 > (trace quad *)
(QUAD *)

CL-USER 4 > (quad 4 3 14)
0 QUAD > ...
  >> A : 4
  >> B : 3
  >> C : 14
    1 * > ...
      >> SYSTEM::ARGS : (3 3)
    1 * < ...
      << VALUE-0 : 9
    1 * > ...
      >> SYSTEM::ARGS : (4 4 14)
    1 * < ...
      << VALUE-0 : 224
0 QUAD < ...
  << VALUE-0 : -215
-215
```

Notes      **\*trace-indent-width\*** is an extension to Common Lisp.

|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                     | Controls how circular structure are printed in trace output.                                                                                                                                     |                 |
| Package                     | <code>hcl</code>                                                                                                                                                                                 |                 |
| Initial value               | <code>nil</code>                                                                                                                                                                                 |                 |
| Description                 | <code>*trace-print-circle*</code> controls how circular structures are printed during output from tracing. It allows the printing of circular structures by the tracer to be controlled indepen- |                 |

dently of the usual printing mechanism, which is governed by `*print-circle*`. `*print-circle*` is bound to the value of `*trace-print-circle*` while printing tracing information.

Example

```
USER 19 > (setq *trace-print-circle* t)
T
USER 20 > (defun circ (l)
             (rplacd (last l) 1)
             1)

CIRC
USER 21 > (trace second)

SECOND
USER 22 > (second (circ '(1 2 3 4)))
0 SECOND > (#1=(1 2 3 4 . #1#))
0 SECOND < (2) 2
```

Notes `*trace-print-circle*` is an extension to Common Lisp.

## **\*trace-print-length\*** *Variable*

Summary The number of components of an object that are printed in trace output.

Package `hcl`

Initial value `100`

Description `*trace-print-length*` controls the number of components of an object which are printed during output from tracing. If its value is a positive integer then the first `*trace-print-length*` components are printed.

`*print-length*` is bound to the value of `*trace-print-length*` while printing tracing information. If `*trace-`

**print-length\*** is **nil** then all the components of the object are printed.

**Example**

```
USER 5 > (trace append)
APPEND
USER 6 > (setq *trace-print-length* 3)

3
USER 7 > (dotimes (i 10) (setq li (if (zerop i)
   nil
   (cons i li)))))

NIL
USER 8 > (append li '(a b))
0 APPEND > ((9 8 7 ...) (A B))
0 APPEND < ((9 8 7 ...))
(9 8 7 6 5 4 3 2 1 A B)
```

**Notes**

**\*trace-print-length\*** is an extension to Common Lisp.

**See also**

**trace**

**\*trace-print-level\***

**Variable**

**Summary**

The depth to which nested objects are printed in trace output.

**Package**

**hcl**

**Initial value**

**5**

**Description**

**\*trace-print-level\*** controls the depth to which nested objects are printed during output from tracing. If its value is a positive integer then components at or above that level are suppressed. By definition an object to be printed is considered to be at level 0, its components are at level 1, their sub-components are at level 2, and so on.

**\*print-level\*** is bound to the value of **\*trace-print-level\*** while printing tracing information. If **\*trace-**

`print-level*` is `nil` then objects are printed without regard to depth.

| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                           |
| Description   | <code>*trace-print-pretty*</code> controls the amount of whitespace printed during output from tracing. If it is not <code>nil</code> then extra whitespace is inserted to make the output more comprehensible. <code>*print-pretty*</code> is bound to the value of <code>*trace-print-pretty*</code> while printing tracing information. |

|          |                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| Examples | <pre>USER 6 &gt; (trace macroexpand-1) MACROEXPAND-1 USER 7 &gt; (setq *trace-print-pretty* t               *print-pretty* nil)</pre> |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|

```

NIL
USER 8 > (defmacro sum (n)
             '(do ((i 0 (1+ i))
                   (res 0 (+ i res)))
                  ((= i ,n) res)))

SUM
USER 9 > (macroexpand-1 '(sum 3))

0 MACROEXPAND-1 > ((SUM 3))
0 MACROEXPAND-1 < ((DO ((I 0 (1+ I))
                           (RES 0 (+ I RES)))
                           ((= I 3)
                            RES))
                        T)
(DO ((I 0 (1+ I)) (RES 0 (+ I RES))) ((= I 3) RES))
T

```

Notes      **\*trace-print-pretty\*** is an extension to Common Lisp.

### **\*trace-verbose\*** *Variable*

Summary     Controls how arguments and values are printed in trace output.

Package     **hcl**

Initial value    **:only**

Description    **\*trace-verbose\*** controls the way arguments and values are printed in trace output.

If the value is not **nil** then **trace** attempts to decode the arguments and values, and prints them.

When the value is **:only**, **trace** does not print the lists of arguments and values after the function name.

Notes      **\*trace-verbose\*** is an extension to Common Lisp.

## try-compact-in-generation *Function*

Summary      Compacts the most fragmented segment(s) in a generation in 32-bit LispWorks.

Package      `hcl`

Signature      `try-compact-in-generation generation-number time-threshold`  
                  `&optional fraction-threshold => result`

Arguments      *generation-number*  
                  0 for the most recent generation, 1 for the  
                  most recent two generations, and so on up to  
                  a maximum (usually 3). Numbers outside  
                  this range signal an error.

*time-threshold*      A real number.

*fraction-threshold*

A real number between 0 and 1, defining the minimum fragmentation to actually compact. The default is 0.25.

Values      *result*      A boolean.

Description      `try-compact-in-generation` finds the most fragmented segment in the generation specified. If *time-threshold* is positive, it compacts this segment, and repeats this operation until *time-threshold* seconds have elapsed. At this point `try-compact-in-generation` returns, with value `t` if at least one segment was compacted and value `nil` otherwise. Because the operation cannot be stopped in the middle, the actual time taken will always be larger than *time-threshold*.

If *fraction-threshold* is 1, `try-compact-in-generation` does nothing. If *fraction-threshold* is 0,

`try-compact-in-generation` will compact all uncompacted segments (unless it runs out of time). With the default (0.25) `try-compact-in-generation` compacts only moderately fragmented segments.

If *time-threshold* is negative, then `try-compact-in-generation` does not actually compact any segments. *result* is a boolean indicating whether `try-compact-in-generation` would actually try to compact a segment if it were to be called with a positive *time-threshold* and the other arguments unchanged.

This function is typically used after a call to `check-fragmentation`. For more information, see “Controlling Fragmentation” on page 144.

**Notes** `try-compact-in-generation` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where `marking-gc` with the *what-to-copy* argument offers similar functionality (although `set-blocking-gen-num` is intended to solve the problem of fragmentation automatically).

`try-move-in-generation`  
“Memory Management in 32-bit LispWorks” on page 135

## try-move-in-generation *Function*

**Summary** Moves objects out of the most fragmented segment(s) in a generation, leaving them empty in 32-bit LispWorks.

**Package** `hcl`

**Signature** `try-move-in-generation generation-number time-threshold &optional fraction-threshold => result`

|             | <i>time-threshold</i>     | A real number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | <i>fraction-threshold</i> | A real number between 0 and 1, defining the minimum fragmentation to actually move. The default is 0.25.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Values      | <i>result</i>             | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description |                           | <p><code>try-move-in-generation</code> finds the most fragmented segment in the generation specified. If <i>time-threshold</i> is positive, it moves objects out of this segment, leaving it empty, and repeats this operation until <i>time-threshold</i> seconds have elapsed. At this point <code>try-move-in-generation</code> returns, with value <code>t</code> if at least one segment was moved and value <code>nil</code> otherwise. Because the operation cannot be stopped in the middle, the actual time taken will always be larger than <i>time-threshold</i>.</p> <p>If <i>fraction-threshold</i> is 1, <code>try-move-in-generation</code> does nothing. If <i>fraction-threshold</i> is 0, <code>try-move-in-generation</code> will move all uncompacted segments (unless it runs out of time). With the default (0.25) <code>try-move-in-generation</code> moves only moderately fragmented segments.</p> <p>If <i>time-threshold</i> is negative, then <code>try-move-in-generation</code> does not actually move any segments. <i>result</i> is a boolean indicating whether <code>try-move-in-generation</code> would actually try to move a segment if it were to be called with a positive <i>time-threshold</i> and the other arguments unchanged.</p> <p>This function is typically used after a call to <code>check-fragmentation</code>. For more information, see “Controlling Fragmentation” on page 144.</p> |

|          |                                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <b>try-move-in-generation</b> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where <b>marking-gc</b> with the <i>what-to-copy</i> argument offers similar functionality (although <b>set-blocking-gen-num</b> is intended to solve the problem of fragmentation automatically). |

| Values      | <i>decl-name</i> A symbol.                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |
| Description | The function <b>undefine-declaration</b> causes <i>decl-name</i> not to be recognized as a declaration. It can be used to undo the effect of <b>define-declaration</b> , but also to undo the effect of proclaiming <i>decl-name</i> as a declaration by <b>proclaim</b> or <b>declare</b> . Note that <b>undefine-declaration</b> is a function, unlike <b>define-declaration</b> which is a macro.<br><br><b>undefine-declaration</b> returns its argument. |  |

| Summary     | A fast queue.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description | The type <code>unlocked-queue</code> is a fast queue (first in, first out) that is unlocked, not thread-safe and does not have waiting functionality. It does not do anything that <code>mailbox</code> cannot do, but it is faster. It is useful when you always access the queue together with other operations that need to be "atomic", so that you need a lock around them anyway, or when queueing and de-queueing is done on the same process. |
| See also    | <code>make-unlocked-queue</code>                                                                                                                                                                                                                                                                                                                                                                                                                      |

## **unwind-protect-blocking-interrupts** *Macro*

|           |                                                                                                                             |                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| Summary   | Does <code>unwind-protect</code> blocking interrupts.                                                                       |                                       |

| Values    | <i>results</i>                                                                                                              | The values of <i>protected-form</i> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <code>unwind-protect-blocking-interrupts</code> executes <i>protected-form</i> with interrupts blocked. On exit, whether local or not, the <i>cleanups</i> are executed with interrupts blocked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | In compiled code, the macro is equivalent to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|             | <pre>(mp:with-interrupts-blocked   (unwind-protect     <i>protected-form</i>     (mp:current-process-block-interrupts)     <i>cleanup1 cleanup2 ...)))</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Notes       | <p>However, in interpreted code the macro is expanded to ensure that the call to <code>(mp:current-process-block-interrupts)</code> actually happens. If the above form is interpreted and <i>protected-form</i> uses <code>current-process-unblock-interrupts</code>, the evaluator may throw (if the process is killed, for example) before calling <code>current-process-unblock-interrupts</code>.</p> <ol style="list-style-type: none"> <li>1. Both the protected form and the cleanups can block and unblock interrupts using <code>current-process-block-interrupts</code> and <code>current-process-unblock-interrupts</code>. Typically the protected form would set up something and then unblock the interrupts. The cleanups may unblock interrupts if some of the cleanups are essential and others are not.</li> <li>2. Blocking interrupts causes the process to not respond to interrupts, including killing. You should make sure that forms which are executed with interrupts blocked do not hang.</li> </ol> |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Does <code>unwind-protect</code> blocking interrupts around the cleanups.                                                                                                                                                                                                                                                                           |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                    |
| Signature   | <code>unwind-protect-blocking-interrupts-in-cleanups <i>protected-form</i> &amp;rest <i>cleanups</i> =&gt; <i>results</i></code>                                                                                                                                                                                                                    |
| Arguments   | <p><i>protected-form</i> A form.</p> <p><i>cleanups</i> Forms.</p>                                                                                                                                                                                                                                                                                  |
| Values      | <i>results</i> The values of <i>protected-form</i> .                                                                                                                                                                                                                                                                                                |
| Description | The macro <code>unwind-protect-blocking-interrupts-in-cleanups</code> executes <i>protected-form</i> . On exit, whether local or not, the <i>cleanups</i> are executed with interrupts blocked.<br><br>In compiled code, the macro is equivalent to                                                                                                 |
|             | <pre>(unwind-protect   <i>protected-form</i>   (mp:with-interrupts-blocked <i>cleanup1 cleanup2 ...</i>)</pre>                                                                                                                                                                                                                                      |
|             | However, in interpreted code the macro is expanded to ensure that the body of <code>mp:with-interrupts-blocked</code> actually happens. If the form above is interpreted the evaluator may throw (if the process is killed, for example) before completing macroexpansion of <code>mp:with-interrupts-blocked</code> and doing the actual blocking. |
| Notes       | <ol style="list-style-type: none"> <li>1. <i>cleanups</i> can block and unblock interrupts using <code>current-process-block-interrupts</code> and <code>current-process-unblock-interrupts</code>. This may be useful if some of the cleanups are essential and others are not.</li> </ol>                                                         |

2. Blocking interrupts causes the process to not respond to interrupts, including killing. You should make sure that forms which are executed with interrupts blocked do not hang.

**variable-information** *Function*

**Summary**      Returns information about the variable bindings of a symbol in an environment.

**Package**      `hcl`

**Signature**      `variable-information variable &optional env => kind,  
localp, decls`

**Arguments**      `variable`      A symbol

`env`      An environment or `nil`

**Values**      `kind`      `nil` or one of the keywords `:special`,  
`:lexical`, `:symbol-macro` and `:constant`.

`localp`      A boolean

`decls`      An a-list

**Description**      The function `variable-information` returns information about how the variable *symbol* is bound in the environment *env*.

The value of *kind* will be as follows:

`nil`      There is no information about *variable* in *env*

`:special`      *variable* has a special binding in *env*

**:lexical**      *variable* has a lexical binding in *env*  
**:symbol-macro** *variable* has a symbol-macro binding in *env*  
**:constant**      *variable* has a constant binding in *env*

*localp* will be true if *variable* is bound by a form that has lexical scope (for example `let`, `lambda`) or false if *variable* has global scope (for example `defvar`).

*decls* is an a-list of declarations that refer to *variable*. The `cdr` of each pair is specified according to the `car` of the pair as follows:

**dynamic-extent**

The `cdr` is non-nil if *variable* is declared **dynamic-extent** in *env*.

**ignore**      The `cdr` is non-nil if *variable* is declared **ignore** in *env*.

**type**      The `cdr` is the type specifier that is declared for *variable* in *env* if any.

Notes      **variable-information** is part of the environment access API which is based on that specified in *Common Lisp: the Language (2nd Edition)*.

| Values      | <code>result</code> | A Lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description |                     | <p>The macro <code>with-ensuring-gethash</code> gets the value for the key <code>key</code> from the hash table <code>hash-table</code>, and if this fails constructs a new value, puts it in the table and returns it. <code>with-ensuring-gethash</code> does this in a thread-safe way, which means that all threads calling it with the same <code>key</code> and <code>hash-table</code> return the same value (as long as nothing removes it from the table).</p> <p>Only one of <code>constructor-form</code> or <code>constructor</code> can be non-<code>nil</code>. When <code>key</code> is not found, <code>constructor-form</code> or <code>constructor</code> is used to construct the new value. If <code>constructor</code> is non-<code>nil</code>, it is called without arguments. If <code>constructor-form</code> is non-<code>nil</code>, it is executed. If both are <code>nil</code>, the new value is <code>nil</code> unless the <code>in-lock-constructor</code> or <code>in-lock-constructor-form</code> construct it. The call or execution of the <code>constructor</code> or <code>constructor-form</code> is done without any lock. The result may be discarded if, by the time it returned, there is a match for the key in the table.</p> <p>Only one of <code>in-lock-constructor</code> or <code>in-lock-constructor-form</code> can be non-<code>nil</code>, which is used when the key is not found after constructing the new value. If <code>in-lock-constructor-form</code> is non-<code>nil</code>, it is executed and the result is the actual value to use (the result of the construction by <code>constructor-form</code> or <code>constructor</code> is ignored). If <code>in-lock-constructor</code> is non-<code>nil</code>, it is called with the result of the construction by <code>constructor-form</code> or <code>constructor</code>, and the result is used as the new value. In either case, the call or execution is done with <code>hash-table</code> locked, and the result is guaranteed to be put in <code>hash-table</code> and returned. If both <code>in-lock-constructor</code> and <code>in-lock-constructor-form</code> are <code>nil</code>, the result of the construction is used.</p> |
| Notes       |                     | <ol style="list-style-type: none"> <li>When both <code>constructor-form</code> and <code>in-lock-constructor-form</code> are <code>nil</code>, <code>gethash-ensuring</code> is probably simpler and better.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

2. In most situations, doing all the construction out of the lock is better than doing anything inside the lock. It means that sometimes the work that was done in the constructions is wasted because another thread put the value in the table, but that overhead is normally less significant than the overhead of holding the lock for longer, with the associated potential deadlocks.

|             | <code>body</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Forms.                                        |
| Values      | <code>results</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                     | The results of evaluating <code>body</code> . |
| Description | <p>The macro <code>with-hash-table-locked</code> evaluates <code>body</code> with the hash table <code>hash-table</code> locked against modification by other threads. The current thread can modify <code>hash-table</code>.<br/><br/><code>with-hash-table-locked</code> is useful not only for multiple accesses to the same table, but also when an access to the table must be consistent with some other operation, avoiding the need to make a separate lock,</p> |                                               |

## **with-heavy-allocation** *Macro*

**Summary** Slows up garbage collection during the execution of code that allocates a lot of space.

**Package** `hcl`

**Signature** `with-heavy-allocation &rest body => result`

**Arguments** `body` The forms for which you want the garbage collector to behave differently from normal.

**Values** `result` The result of executing `body`.

**Description** The macro `with-heavy-allocation` is for use with code that allocates a lot of space but is not interactive. It ensures that garbage collection (GC) is carried out less frequently while these forms are being executed. However, each GC may take longer.

**Compatibility notes** In LispWorks 5.0 `with-heavy-allocation` is implemented only in 32-bit LispWorks. In version 5.1 and later it is implemented in 64-bit LispWorks as well.

## with-output-to-fasl-file

### dump-form

### dump-forms-to-file

### *Macro and Functions*

**Summary**      Dump forms to a file in a binary format, which can then be loaded using `load-data-file`.

**Package**      `hcl`

**Signature**      `with-output-to-fasl-file (fasl-stream-var pathname &key overwrite dump-standard-objects delete-on-error) &body body => nil`  
  
`dump-form form fasl-stream => nil`  
  
`dump-forms-to-file pathname forms &key overwrite dump-standard-objects delete-on-error => nil`

**Arguments**      `fasl-stream-var`    A variable.

`pathname`        A pathname designator.

`overwrite`       A boolean.

`dump-standard-objects`

                      A boolean.

`delete-on-error` A boolean.

`body`            Lisp code that calls `dump-form`.

`form`            A form.

`fasl-stream` The value of `fasl-stream-var`.

`forms`          A list of forms.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Values      | Each of these macros and functions returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description | <p>The macro <code>with-output-to-fasl-file</code> and the functions <code>dump-form</code> and <code>dump-forms-to-file</code> allow you to dump forms to a file in a binary format, which can then be loaded using <code>load-data-file</code>.</p> <p>They provide these two ways to achieve the same thing:</p> <ul style="list-style-type: none"> <li>• <code>dump-forms-to-file</code> simply dumps the forms in <i>forms</i> into the file specified by <i>pathname</i>.</li> <li>• <code>with-output-to-fasl-file</code> binds <i>fasl-stream-var</i> to an opaque structure associated with <i>pathname</i>. Inside the <i>body</i>, <code>dump-form</code> is used to dump individual forms to the file.</li> </ul> <p><i>overwrite</i> specifies what to do if <i>pathname</i> already exists. If <i>overwrite</i> is non-nil, <code>dump-forms-to-file</code> and <code>with-output-to-fasl-file</code> overwrite the existing file, otherwise they signal an error. The default value of <i>overwrite</i> is <code>t</code>.</p> <p><i>delete-on-error</i> specifies what to do in case of a non-local exit from the <i>body</i> of <code>with-output-to-fasl-file</code> or from <code>dump-forms-to-file</code> (typically abort after an error). By default, the file is deleted, but if <i>delete-on-error</i> is <code>nil</code> then the file is left as it is. The default value of <i>delete-on-error</i> is <code>t</code>.</p> <p><i>dump-standard-objects</i> specifies what to do when trying to dump a standard object (that is, an instance of a subclass of <code>standard-object</code>) which does not have a user-defined <code>make-load-form</code>. If <i>dump-standard-objects</i> is <code>nil</code>, an error is signaled. If <i>dump-standard-objects</i> is non-nil, the instance is dumped using <code>make-load-form-saving-slots</code>. The default value of <i>dump-standard-objects</i> is <code>nil</code>.</p> <p>When the generated file is loaded by <code>load-data-file</code>, the forms are loaded and by default evaluated, though <code>load-data-file</code> can also load without evaluating. If <i>callback</i> is passed to <code>load-data-file</code>, it gets each of the results. Otherwise the results are discarded (except being printed when</p> |

passing `:print t`). Hence to be useful, either `load-data-file` must be called with *callback*, or evaluation of the forms should have some side effect, for example setting the value of some special symbol or adding entries to some global table.

For a form which is not a list or an object with `make-load-form`, or is a quoted list, `eval` does nothing. Dumping such forms and then using the *callback* in `load-data-file` to do some work with them is the natural way of using `dump-forms-to-file` or `with-output-to-fasl-file` and `load-data-file` to transfer large amounts of data.

Files generated by `dump-forms-to-file` or `with-output-to-fasl-file` can be loaded (by `load-data-file`) on any LispWorks platform with the same byte order. All x86/x64 architectures have the same byte order (little-endian), so `load-data-file` on any x86/x64 architecture can be used to load a data file that was generated on any x86/x64 architecture. The ARM architectures have the same byte order as x86/x64. The reverse byte order (big-endian) is used by AIX and SPARC (old Solaris).

## Notes

1. The dumping of objects is done the same way that `compile-file` dumps when it creates a fasl file, except for the treatment of standard objects when `dump-standard-objects` is non-nil.
2. Dumping means creating a deep copy of the form. The elements and slots of lists, arrays of element type `t`, structures (unless they have a `make-load-form`), and, when `dump-standard-objects` is non-nil, standard objects without `make-load-form` are dumped recursively.
3. `dump-forms-to-file` and `with-output-to-fasl-file` cope with cyclic structures.
4. If you want to dump parts of cyclic structures, you can stop the recursion by defining an appropriate `make-load-form` method for the objects at the nodes where the recursion should stop.

5. A fasl file created using `with-output-to-fasl-file` must be loaded only by `load-data-file`, and not by `load`.

Example

```
(dump-forms-to-file "my-forms.data"
  '(#(1 2 3)
    89
    (* 7 7)
    '(* 9 9)))
```

Note that the first \* form lacks a quote while the second has a quote.

Then (potentially in a different LispWorks version and/or on a different architecture) this:

```
(load-data-file "my-forms.data"
  :callback 'print)
```

prints this:

```
 #(1 2 3)
 89
 49
 (* 9 9)
```

In contrast, loading the same binary file without evaluation:

```
(load-data-file "my-forms.data"
  :callback 'print
  :eval nil)
```

prints this:

```
 #(1 2 3)
 89
 (* 7 7)
 (QUOTE (* 9 9))
```

| Summary     |                 | Locks a ring such that no other thread can access it while some code is executed.                                                                                                                                                                                                                       |
| Package     |                 | <code>hcl</code>                                                                                                                                                                                                                                                                                        |
| Signature   |                 | <code>with-ring-locked (ring &amp;optional whostate timeout) &amp;body body =&gt; result</code>                                                                                                                                                                                                         |
| Arguments   | <i>ring</i>     | A ring object created by <code>make-ring</code> .                                                                                                                                                                                                                                                       |
|             | <i>whostate</i> | The status of the process while the ring is locked.                                                                                                                                                                                                                                                     |
|             | <i>timeout</i>  | A timeout period, in seconds.                                                                                                                                                                                                                                                                           |
|             | <i>body</i>     | Lisp code.                                                                                                                                                                                                                                                                                              |
| Values      | <i>result</i>   | The result of executing <i>body</i> .                                                                                                                                                                                                                                                                   |
| Description |                 | <p>The macro <code>with-ring-locked</code> locks the ring <i>ring</i> that during the execution of <i>body</i> no other thread can access ring, whether for modification or merely reading values.</p> <p><i>whostate</i> and <i>timeout</i> are used in the same way as in <code>with-lock</code>.</p> |

|           |             | <i>Macro</i>                                                   |
|-----------|-------------|----------------------------------------------------------------|
| Summary   |             | Prevents generation of code coverage for a body of code.       |
| Package   |             | <code>hcl</code>                                               |
| Signature |             | <code>without-code-coverage &amp;body body =&gt; result</code> |
| Arguments | <i>body</i> | Lisp forms.                                                    |

|             |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>result</i> | The result of evaluating <i>body</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |               | <p>The macro <code>without-code-coverage</code> prevents generation of code coverage for the forms of <i>body</i>.<br/> <i>body</i> is evaluated as an implicit <code>progn</code>, except that inside <i>body</i> the compiler does not generate code coverage counters, unless <code>force</code> was supplied non-nil to <code>generate-code-coverage</code> OR <code>with-code-coverage-generation</code>.<br/> <code>without-code-coverage</code> is useful for error forms that you do not want to be counted.</p> |
| Notes       |               | <p>There will be a counter for the <code>(without-code-coverage ...)</code> form itself. If you do not want this counter, use <code>error-situation-forms</code> instead.</p>                                                                                                                                                                                                                                                                                                                                            |
| See also    |               | <code>error-situation-forms</code><br><code>generate-code-coverage</code><br><code>with-code-coverage-generation</code>                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>write-string-with-properties</b> |                   | <i>Function</i>                                                                                                  |
|-------------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------|
| Summary                             |                   | Writes the string to the stream, and adds properties if the stream supports it.                                  |
| Package                             |                   | <code>hcl</code>                                                                                                 |
| Signature                           |                   | <code>write-string-with-properties string properties &amp;optional stream &amp;key start end =&gt; string</code> |
| Arguments                           | <i>string</i>     | A string.                                                                                                        |
|                                     | <i>properties</i> | A property list.                                                                                                 |
|                                     | <i>stream</i>     | An output stream designator.                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                               |

| Values      | <i>string</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A string.                                     |
| Description | <p>The function <code>write-string-with-properties</code> writes a part of <i>string</i>, bounded by <i>start</i> and <i>end</i>, to <i>stream</i> exactly like <code>cl:write-string</code> does, and then adds <i>properties</i> if <i>stream</i> supports this operation. Currently the only types of <code>stream</code> that support properties are Editor streams, which means streams that write to Editor buffers.</p> <p><i>properties</i> must be a property list, with alternating <i>key</i> and <i>value</i>. When adding the properties, each pair of <i>key</i> and <i>value</i> is processed separately, in the order they occur in the list.</p> <p>If <i>key</i> is <code>:highlight</code>, then <i>value</i> must specify a <code>editor:face</code>. It can be an <code>editor:face</code> object, a face name (which means a symbol that was used as the name in <code>editor:make-face</code>), or one of the following keywords:</p> <ul style="list-style-type: none"> <li><code>:underline</code> Underline the text.</li> <li><code>:bold</code> Make the text bold.</li> <li><code>:italic</code> Make the text italic.</li> <li><code>:bold-italic</code> Make the text bold and italic.</li> <li><code>:inverse</code> Invert the background and foreground.</li> <li><code>:compiler-error-highlight</code><br/>or <code>:compiler-warning-highlight</code><br/>or <code>:compiler-note-highlight</code><br/>The faces that the compiler use when it outputs to an editor buffer.</li> <li><code>:editor-error-highlight</code><br/>The face that the editor uses in the echo area when it reports an editor error.</li> </ul> |                                               |

If `key` is `:menu-items`, `value` specifies menu items that are added to the context menu that is displayed when the current point is inside `string` in the Editor buffer. The value must be a list where each element specifies a menu-item by a list of three elements: `title`, `function` and `arg`. `title` must be a string, and is what the end user sees. If the user selects this item, `function` is called with `arg` as a single argument.

If `key` is not `:menu-items` or `:highlight`, the `key / value` is added as a text property using `editor:put-text-property`, with `key` as the `property` argument and `value` as `value`.

**Example** Output "A string in bold" in bold face to `mp:*background-standard-output*`:

```
(write-string-with-properties
  "A string in bold"
  '(:highlight :bold)
  mp:*background-standard-output*)
```

**Note** `write-string-with-properties` can be used wherever `write-string` is used, because it does exactly the same for streams that do not implement properties.

The LispWorks compiler uses `write-string-with-properties` to write compiler errors, warnings and notes with `:complier-....-highlight` keywords above. This is how it produces the colored errors/warnings/notes when it writes to the Listener or is invoked in the Editor.

Support for `:menu-items` is implemented by the method:

```
(method capi:pane-popup-menu-items
  (capi:editor-pane capi:interface))
```

Therefore, if this method is not called, for example if you make a `capi:editor-pane` and pass it `:pane-menu`, then items will not be added to the menu.

## The LINK-LOAD Package

This chapter describes the symbols in the `LINK-LOAD` package.

**Note:** this chapter applies only to LispWorks for SPARC Solaris.

| Arguments   | <code>stream</code>                                             | An output stream for message reporting. If set to <code>nil</code> , then no output will be produced.<br>By default this is <code>t</code> .                                                                                                                                                                                                                                                 |
| Description |                                                                 | The function <code>break-on-unresolved-functions</code> produces break-on-entry code for all currently undefined but referenced (that is, unresolved) foreign symbols, so that if an undefined foreign function is called from within the foreign code, a Lisp error will occur. Break-on-entry code will also be produced for any new unresolved symbols loaded later in your Lisp session. |

The special variable `foreign:*break-on-unresolved-functions*` will, when set to non-nil, produce break-on-entry code for all new unresolved symbols that are loaded, but won't do so for symbols already loaded. By default this variable is set to nil.

## **foreign-symbol-address** *Function*

Package [link-load](#)

Signature `foreign-symbol-address name &key errorp functionp => result`

Arguments `name` The name of a foreign symbol.

`errorp` A boolean.

`functionp` A boolean.

Values `result` The address of `name` or `nil`.

Description The function `foreign-symbol-address` is used to find out whether a foreign symbol is defined, by looking for it in the foreign-symbol table. If its associated object code has been loaded into the image, its address is returned. Otherwise nil is returned, unless `errorp` is `nil`.

The `errorp` keyword defines the behavior of the function when a symbol has not been defined. If it is non-nil (which is the default value), then an error will be signaled. If it is `nil`, no error will be reported, and the function will return `nil`.

The `functionp` keyword is used to specify the kind of symbol sought. If it is t, `foreign-symbol-address` will assume that `name` is the name of a function. If it is `nil` it will assume that `name` is the name of a variable. The default value is t.

Example      `(foreign-symbol-address 'chmod)`

## **get-foreign-symbol**

## *Function*

Package     `link-load`

Signature    `get-foreign-symbol name &optional force => result`

Arguments    *name*        A symbol or string.

*force*        A keyword.

Values        *result*      A foreign symbol.

Description    This function gets a foreign symbol or it may be used to explicitly register an undefined symbol.

*name* is a symbol or string to look up or to create as a foreign symbol. If it is a symbol, the symbol looked for is that which the function `lisp-name-to-foreign-name` would produce. If *name* is a string, it is taken literally

If supplied and the symbol is not already defined as a foreign symbol, *force* forces it to be an undefined foreign symbol. This provides a reference to the symbol so that a subsequent call to `read-foreign-modules` will attempt to resolve it

Example      `(get-foreign-symbol 'my-func-not-yet-loaded t)`

Notes        It is not usually necessary to use this function. In order to examine whether a foreign symbol is defined, use `foreign-symbol-address`. The act of defining a foreign function using `fli:define-foreign-function` makes the symbol undefined, so the use of force is not usually needed.

| Arguments   | <i>name</i>                                                                                                                                                                                                                                                                                                                                                     | A symbol representing a Lisp name. (Strings are passed unchanged through the function.) |
|             | <i>language</i>                                                                                                                                                                                                                                                                                                                                                 | If :c then an equivalent ‘C’ name is produced. :FORTRAN is an alternative.              |
| Description | This function provides an equivalent foreign name for a Lisp name, depending on the keyword language.                                                                                                                                                                                                                                                           |                                                                                         |
| Values      | A string is returned which is a foreign equivalent of the Lisp name supplied. If name is a string, the function returns the string unchanged. If language is a symbol, the ‘C’ version replaces occurrences of ‘-’ with ‘_’ and adds a leading underscore. The Fortran version replaces occurrences of ‘-’ with ‘_’ and adds a leading and trailing underscore. |                                                                                         |
| Example     | <b>(lisp-name-to-foreign-name 'lisp-name-with-hyphens)</b><br><b>"_lisp_name_with_hyphens"</b>                                                                                                                                                                                                                                                                  |                                                                                         |

| Arguments   | <code>module-names</code> A sequence of strings or pathnames.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values      | <code>t</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description | <p>The function <code>read-foreign-modules</code> reads object files of various formats into the Lisp image. Unresolved references are resolved wherever possible and the names of the foreign functions are made available to the Lisp for direct calling from the Lisp if desired. With no argument, <code>read-foreign-modules</code> scans the default libraries looking for definitions of referenced but undefined symbols.</p> <p>The <code>module-names</code> argument is a sequence of items representing object files to be loaded. The items may be of type string or pathname, and will be used to look up a corresponding file in the file system. The only exception is if an item is a string beginning “-1” in which case the rest of the string is used to look up a library file using format strings constructed from the values of the variable <code>*default-library-name-search-paths*</code>, the environment variable <code>LD_LIBRARY_PATH</code> and the variable <code>*default-library-names*</code>. Object files of various formats and library files can be handled by <code>read-foreign-modules</code>.</p> |
| Example     | <pre>(read-foreign-modules "/usr/users/clc/projects/head.o"                       "~clc/projects/libs.a"                       "-1W")</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Notes       | <p>The function <code>read-foreign-modules</code> actually adds the module-names to the list of modules in the variable <code>*default-libraries*</code> and then tries to resolve any undefined symbols using this list. The function <code>get-foreign-symbol</code> may be called to explicitly force a symbol onto the undefined list or the act of defining a foreign function (<code>fli:define-foreign-function</code>) will do it implicitly.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

`read-foreign-modules` may be called at any time during the running of a program and a particular object file may be loaded as often as is necessary.

A warning of any new unresolved references will be printed out after the reading has finished if the flag `*unresolved-messages*` is set to `t` (the default is `nil`). By default messages are printed out about which object modules are being loaded. This may be switched off by setting `*coff-loading-verbose*` to `nil`.

## The LISPWORKS Package

This chapter describes symbols available in the `LISPWORKS` package. This package is used by default. Its symbols are visible in the `CL-USER` package.

Various uses of the symbols documented here are discussed throughout this manual.

|             |                                         | <i>Type</i>                                                                                                                                    |
|-------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The 8 bit string type.                  |                                                                                                                                                |
| Package     | <code>lispworks</code>                  |                                                                                                                                                |
| Signature   | <code>8-bit-string <i>length</i></code> |                                                                                                                                                |
| Arguments   | <code><i>length</i></code>              | The length of the string (or <code>*</code> , meaning any).                                                                                    |
| Description |                                         | The type of strings that can hold simple chars of codes 0...255. This is the string type that is guaranteed to always take 8 bits per element. |

| <b>16-bit-string</b> | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary              | The 16 bit string type.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## **base-character** *Type*

Summary      The base character type.

Package      `lispworks`

Signature      `base-character`

Description      The type of base characters.

`base-character` is a synonym for the Common Lisp type `base-char`.

See also      `base-char-code-limit`

## **base-character-p** *Function*

Summary      A predicate for base characters.

Package      `lispworks`

Signature      `base-character-p object => result`

Arguments      `object`                  The object to be tested.

Values      `result`                  A boolean.

## **bmp-string**

### **simple-bmp-string**

*Types*

**Summary** String types that hold `bmp-chars`.

**Package** `lispworks`

**Description** The type `bmp-string` is a string that can hold `bmp-chars`, that is characters with code below `#x10000` (that is 16-bit). This corresponds to the Basic Multilingual Plane of Unicode.

`simple-bmp-string` is the simple version of `bmp-string`, that is it is a simple-array of `bmp-chars`.

**Notes**

1. `bmp-strings` use less memory than `c1:character` strings (type `text-string`), but cannot hold supplementary characters (that is, characters with code `#x10000` or greater).
2. The corresponding character type is `bmp-char`.

**Compatibility note** `bmp-string` was new in LispWorks 7.0. In LispWorks 6.1 and earlier versions `text-string` is similar to `bmp-string`. However, in most cases where you use `text-string` you probably still want to use `text-string` (using its new meaning, covering all the Unicode range).

**bmp-string-p****simple-bmp-string-p***Functions*

Summary      The predicates for **bmp-string** and **simple-bmp-string**.

Package      **lispworks**

Signature      **bmp-string-p** *object* => *result*  
**simple-bmp-string-p** *object* => *result*

Arguments      *object*      A Lisp object.

Values      *result*      A boolean.

Description      The functions **bmp-string-p** and **simple-bmp-string-p** test whether their argument is a **bmp-string** or a **simple-bmp-string** respectively.

See also      **bmp-string**  
                 **simple-bmp-string**

**\*browser-location\****Variable*

Signature      **\*browser-location\***

Package      **lispworks**

Initial value      **nil**

Description      Controls how the online documentation interface and the function **open-url** find a web browser executable (either Netscape, Firefox, Mozilla or Opera) to use. The value should be **nil** or a string.

If the value is **nil**, LispWorks attempts to find the browser using the value of the environment variable **PATH**.

If the value is a string, it specifies the directory in which the browser is installed. Typical values are `"/usr/bin/"` and `"/usr/local/bin/"`.

**Note:** do not omit the trailing slash.

**Note:** `*browser-location*` is used only in the Motif-based IDE.

| Summary                 | Calls the next piece of advice associated with a function.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Package                 | <b>lispworks</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signature               | <b>call-next-advice args</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments               | <code>args</code> are arguments to be given to the next piece of advice to be called. Any number of arguments may be given in this way, including keyword arguments, and there is no requirement for pieces of around advice to receive the same number of arguments as the original definition expected.                                                                                                                                                                                                     |
| Values                  | <b>call-next-advice</b> returns the values produced by the call to the next piece of advice (or to the combination of before and after advice and the original definition).                                                                                                                                                                                                                                                                                                                                   |
| Description             | <b>call-next-advice</b> is the local function used to invoke the next item in the ordering of pieces of advice associated with a function. It can only be called from within the scope of the around advice. Advice may be attached to a function by <b>defadvice</b> and this allows the behavior of a function to be modified. Extra code to be performed before or after the function may be simply added by creating before or after advice for it. Around advice is more powerful and replaces the orig- |

inal definition. All the advice for a function is ordered with the around advice coming first.

The first piece of around advice receives the arguments to the function and may return any values at all. It has access to the rest of the advice, and to the original definition, by means of `call-next-advice`. A call to this from within the body of the around advice invokes the next piece of around advice with the arguments given to `call-next-advice`. The last piece of around advice in the ordering invokes the sequence of before advice, the original definition, and after advice if it calls `call-next-advice`. Around advice may contain any number of calls to `call-next-advice`, including no calls.

Notes

1. `call-next-advice` is an extension to Common Lisp. See Chapter 6, “The Advice Facility” for a broader discussion of `advice`.

`call-next-advice` is not like `cl:call-next-method`, where passing no arguments has a special meaning. To pass the same arguments to the next advice, you need something like:

```
(lw:defadvice (my-func my-func-advice :around)
  (a b c &rest other-args)
  (format t "my-func advice-%")
  (apply #'lw:call-next-advice a b c other-args)
)
```

or

```
(lw:defadvice (my-func my-func-advice :around)
  (&rest args)
  (format t "my-func advice-%")
  (apply #'lw:call-next-advice args)
)
```

| Arguments | <p><i>system-name</i> A symbol representing the name of the system. The system must have been defined already using the <code>defsystem</code> macro.</p> <p><i>force</i> If <code>t</code> then all the files in the system are compiled regardless. (This argument was formerly called <code>force-p</code>. The old name is currently still accepted for compatibility.)</p> <p><i>simulate</i> If <code>nil</code> or not present then <code>compile-system</code> works silently. Otherwise a plan of the actions which <code>compile-system</code> intends to carry out is printed. What happens next depends on the value of <i>simulate</i>:</p> <ul style="list-style-type: none"> <li><code>t</code> — do nothing.</li> <li><code>:ask</code> — you are asked if you wish the plan to be carried out using <code>y-or-n-p</code>.</li> <li><code>:each</code> — <code>compile-system</code> displays each action in the plan one at a time, and asks you whether you want to carry out this particular action. The answer <code>c</code> executes the rest of the plan without further prompting, returns from <code>compile-system</code> without further processing, and <code>y</code> and <code>n</code> work as expected.</li> </ul> <p><code>:simulate</code> may be abbreviated as <code>:sim</code>.</p> <p><i>load</i> If <code>t</code> then <code>load-system</code> is called after <code>compile-system</code> has finished. If <code>:no</code> then no files are loaded at all. The default is <code>nil</code>.</p> <p><i>args</i> Arguments to be passed directly to the compiler.</p> |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>target-directory</i> | This must be a string representing a valid directory. It defaults to the <code>:default-pathname</code> option to <code>defsystem</code> . This is the directory where the object files created are put. If the <i>target-directory</i> is given then dependency information expressed in the system rules is ignored. <code>:target-directory</code> may be abbreviated as <code>:t-dir</code> .                                                                                                                                                                                                   |
| Values                  | <code>compile-system</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Examples                | <pre>(compile-system 'blackboard :simulate :ask)  (compile-system 'tms :load t)  (compile-system 'packages :load :no                  :target-directory "/usr/users/386i/")</pre>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Notes                   | If <code>load</code> is <code>t</code> then <code>load-system</code> is called after the system has been compiled.<br><br>C source files, for example <code>foo.c</code> , can be included in a system (see the use of <code>:default-type</code> and <code>:type</code> in <code>defsystem</code> ). The corresponding object file name is <code>foon.so</code> on Linux, FreeBSD, AIX and x86/x64 Solaris, <code>foon.dylib</code> on Mac OS X and <code>foon.o</code> on SPARC Solaris, where <i>n</i> is a platform-specific integer. On Windows the object file name is <code>foo.dll</code> . |

| Description | <p>This function produces a single, concatenated fasl, <i>output-file</i>, from a list of individual systems (named amongst the <i>args</i>). Since concatenated fasl files may be produced in this way, you do not need to be wary of MS filename conventions if developing sources on UNIX for a Microsoft Windows application. This clearly allows more freedom for naming source files. However, <i>output-file</i> must, in such cases, be a MS-Window-compatible filename.</p> <p>If <i>simulate</i> is <code>nil</code> or is not present, <code>concatenate-system</code> will work silently. Otherwise, a plan of the actions which</p>                              |

`concatenate-system` intends to carry out is printed. What happens next depends upon the value of *simulate*:

- If it is `t`, the function does nothing.
- If `:ask`, then the user is asked, using `y-or-n-p`, if the plan should be carried out.
- If it is `:each`, the user is asked at each stage in the plan if the current action should be carried out. The responses `y` and `n` work as normal. If `e` is typed, `concatenate-system` exits without further processing.

If *source-only* is `t`, files will be loaded only if they are sources.

If, when searching *target-directory* for an object file, the file cannot be found, the appropriate source file from the system's default directory will be loaded instead.

| <i>from</i>      | A pathname designator.                                                                                                                                |             |                        |           |                        |
| <i>to</i>        | A pathname designator.                                                                                                                                |             |                        |           |                        |
| Description      | The function <code>copy-file</code> copies the contents of the file <i>from</i> to another file. The file <i>from</i> must exist.                     |             |                        |           |                        |

`copy-file` opens *from* for input and *to* for output using *if-exists :supersede* (see `cl:open` in the *Common Lisp Hyper-Spec*) and copies the contents from *from* to *to*.

On any failure `copy-file` signals an error.

`copy-file` does not return a useful value.

## count-regexp-occurrences *Function*

Summary Count the occurrences of a pattern in a string.

Package `lispworks`

Signature `count-regexp-occurrences pattern string &key start end overlap  
case-sensitive => count`

Arguments `pattern` A string or precompiled regular expression object.

`string` A string.

`start, end` Bounding index designators of *string*.

`overlap` A generalized boolean.

`case-sensitive` A generalized boolean.

Values `count` An integer.

Description The function `count-regexp-occurrences` counts the occurrences of *pattern* in the part of *string* bounded by *start* and *end*.

If *pattern* is a string, `count-regexp-occurrences` precompiles it first. If you use `count-regexp-occurrences` with the same pattern string several times, it is better to precompile it using `precompile-regexp`.

*start* and *end* have the same meaning as in `count` and other Common Lisp sequence functions.

`case-sensitive` controls whether a string *pattern* is precompiled as a case sensitive or case insensitive search. A non-nil value means a case sensitive search. The value `nil` (the default) means a case insensitive search.

If *overlap* is false (the default), then `count-regexp-occurrences` counts matches that do not overlap. If *overlap* is non-nil, matches can overlap, and `count-regexp-occurrences` finds all of the ways in which the pattern can be matched inside *string*.

The regular expression syntax used by `count-regexp-occurrences` is similar to that used by Emacs, as described in the "Regular expression syntax" section of the *LispWorks Editor User Guide*. If you use **Help > Search** to locate this section in the LispWorks IDE, then select the **Contents** radio button.

### Examples

```
(count-regexp-occurrences "aaa" "aaaaaa")

| Values                  | <i>pathname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A pathname.              |
| Description             | <p>The function <b>current-pathname</b> is useful for loading other files relative to a file.</p> <p><b>current-pathname</b> computes a pathname from the current operation as follows:</p> <ul style="list-style-type: none"> <li>When loading a file<br/>Uses <b>*load-pathname*</b>.</li> <li>When compiling a file<br/>Uses <b>*compile-file-pathname*</b>.</li> <li>When evaluating or compiling an Editor buffer<br/>Uses the pathname of the buffer, if available, otherwise uses the current working directory.</li> <li>Otherwise<br/>Uses the current working directory.</li> </ul> |                          |

The pathname computed above is then translated to a physical pathname, and the argument *relative-pathname* is merged with this physical pathname. The `pathname-type` of the result `pathname` is set to *type* if supplied, the `pathname-version` is set to `:newest`, and `pathname` is returned.

A useful value for *type* is `nil`, which can be used to allow `load` to choose between lisp or fasl regardless of the type of the current pathname.

**Notes**      `defsystem` uses `current-pathname` with its `:default-host` argument.

**Examples**      Suppose you want the file `foo` to load the file `bar`.

While loading the source file `foo.lisp`:

```
(current-pathname "bar")
=>
#P"C:/temp/bar.lisp"
```

While loading the binary file `foo.ofasl`:

```
(current-pathname "bar")
=>
#P"C:/temp/bar.ofasl"
```

To load `bar.lisp` or `bar.ofasl` according to the value of `*load-fasl-or-lisp-file*`, regardless of whether `foo.lisp` or `foo.ofasl` is being loaded, specify *type nil*:

```
(load (current-pathname "bar" nil))
```

**See also**      `defsystem`  
`pathname-location`

## **defadvice** *Macro*

**Summary**      Defines a new piece of advice.

**Package**      `lispworks`

|           |                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|           | <i>where</i>                                                                                                                                                                                               | Specifies where this advice should be placed in the ordering of pieces of advice for the function. By default a piece of advice is placed at the start of the corresponding section. If this argument is present and is <code>:end</code> then the advice is instead placed at the end of its section. The other permissible value for this argument is <code>:start</code> , which places the advice at the start of its section in the ordering (as in the default behavior). |

| Values    | <b>defadvice</b> returns <code>nil</code> .                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>defadvice</code> is the macro used to define a new piece of advice. Advice provides a way to change the behavior of existing functional definitions in the system. In a simple instance advice might be used to carry out some additional actions before or after the original definition. More sophisticated uses allow the definition to be replaced by new code that can access the original function repeatedly or as rarely as desired, and that can receive different numbers of arguments and return any values. A function may have any number of pieces of advice attached to it by using <code>defadvice</code>.</p> <p>When <i>function-dspec</i> names a macro, then the function with which the advice is associated is the expansion function for that macro. Thus before and after advice for a macro receive the arguments given to the macro expansion function, which are normally the macro call form and an environment.</p> <p>There are three kinds of advice that may be defined: before, after and around advice. The first two kinds attach auxiliary code to be carried out alongside the original definition (before it for before advice, after it in the case of after advice). Around advice replaces the function altogether; it may define code that never accesses the original definition, that receives different numbers of arguments, and returns different values. All the pieces of advice for a function are ordered. The ordering is important in determining how all the pieces of advice for a function are combined. Around advice always comes first, then before advice, then the original definition, and lastly the after advice.</p> <p>Conceptually the before advice, the original definition and the after advice are amalgamated into one new construct. If this gets called then each of its components receives the same arguments in turn, and the values returned are those produced by the last piece of after advice to be called in this way (or the original function if there is no after advice). The code associated with before and after advice should not destructively modify its arguments.</p> |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If around advice is present then the first piece of around advice is called, instead of the combination involving before and after advice discussed above. It does not have to access any of the other advice, nor the original definition. Its only link to the rest of the advice is by means of a call to `call-next-advice`. It may invoke this as often as it chooses, and by doing so it accesses the next piece of around advice if present, or else it accesses the combination of before and after advice together with the original definition.

Remove advice using `remove-advice` or `delete-advice`.

Notes      `defadvice` is an extension to Common Lisp.

## **\*default-action-list-sort-time\*** *Variable*

Summary     Determines when actions in action lists are sorted.

Package     `lispworks`

Signature    `*default-action-list-sort-time*`

Initial value    `:execute`

Description    The variable `*default-action-list-sort-time*` is a keyword that is either `:execute` or `:define-action`, denoting when actions in action-lists are sorted (see `define-action-list` for an explanation of ordering specifiers). Actions are sorted either at time of definition (`:define-action`) or when their action-list is executed (`:execute`). The default sort time is `:execute`.

| Description | <p>This parameter provides defaults for all character type parameters. The legal values are <code>cl:base-char</code>, <code>lw:bmp-char</code> and <code>cl:character</code>. <code>lw:simple-char</code> is also supported for backwards compatibility.</p> <p>Its value must only be set via a call to <code>set-default-character-element-type</code>.</p> <p>This is intended for efficiency of applications with only 8-bit strings, where you can do</p> <pre>(set-default-character-element-type 'base-char)</pre> <p>and also for efficiency of applications with only 16-bit strings, where you can do</p> <pre>(set-default-character-element-type 'lw:bmp-char)</pre> <p>If your program uses 16-bit or 32-bit strings you should already be aware of these issues, and make some attempt to provide explicit types.</p> <p>When the compiler does type inferencing it behaves as if this variable was bound to <code>cl:character</code>; if you want assumptions about types to be hard-coded into your program, you must supply explicit declarations and type arguments.</p> |

| <i>name-or-list</i> | A list or action list object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                     |                               |                    |                        |             |            |              |         |
| <i>action-name</i>  | A general lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     |                               |                    |                        |             |            |              |         |
| <i>data</i>         | An object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |                               |                    |                        |             |            |              |         |
| <i>specs</i>        | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                     |                               |                    |                        |             |            |              |         |
| Description         | <p>The macro <code>define-action</code> adds a new action to the action list specified by <i>name-or-list</i>; this action will be executed according to the action-list's execution-function (see <code>execute-actions</code>) when executed. If the action-list specified by <i>name-or-list</i> does not exist, then this is handled according to the value of <code>*handle-missing-action-list*</code>.</p> <p><i>name-or-list</i> is evaluated to give either a list UID (to be looked up in the global registry of lists) or an action list object. <i>action-name</i> is a UID (general lisp object, to be compared by <code>equalp</code>). It uniquely identifies this action within its list (as opposed to among all lists).</p> <p><i>data</i> specifies an object referring to data relevant to the action.</p> <p><i>specs</i> is a free-form list of ordering specifiers and extra key-words, used to control more details of how and when this action is executed.</p> <p>Action-items are normally expected not to be redefined. If an action-item with that action-name already exists in the</p> |                     |                               |                    |                        |             |            |              |         |

action-list (that is, one with an identifier `equalp` to the action-name), then the notification and subsequent handling of this attempt is controlled by the values in the list `*handle-existing-action-in-action-list*`. This is to prevent problems due to re-evaluating an action definition inappropriately. Notification and redefine behavior can be overridden by using the `:force` keyword argument. In this case, any required redefinition is performed unconditionally and without notification.

The following keywords are recognized in the `specs` argument:

- |                                                                                                                                                                                      |                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:after</code>                                                                                                                                                                  | The following element in <code>specs</code> is a UID.<br><code>:after</code> specifies that the action-item being defined must be run after the action-item named. If there is no action-item with a matching name, the restriction is ignored. |
| <code>:before</code>                                                                                                                                                                 | Like <code>:after</code> , but this action-item must be run before the one specified.                                                                                                                                                           |
| <br><code>:after</code> and <code>:before</code> can be specified as many times as necessary to describe the ordering constraints of this action-item with respect to its neighbors. |                                                                                                                                                                                                                                                 |
| <code>:once</code>                                                                                                                                                                   | Specifies that this action-item should be executed only once; after execution, it is disabled.                                                                                                                                                  |
| <code>:force</code>                                                                                                                                                                  | Specifies that this definition should override any previous definition of this action-item, rather than be subject to the value of <code>*handle-existing-action-in-action-list*</code> .                                                       |

#### Example

```
(define-action :network-startup "Reset decnet buffers"
  '(decnet::reset-network-buffers
    *net-buffers*)
  :after "Reset core network"
  :once))
```

## define-action-list *Macro*

Summary      Defines a registered action list.

Package      `lispworks`

Signature      `define-action-list uid &key documentation sort-time dummy-actions default-order execution-function =>`

Arguments      `uid`      A Lisp object.

`documentation`      A string.

`sort-time`      One of `:execute` or `:define-action`.

`dummy-actions`      A list.

`default-order`      A list.

`execution-function`      A function.

Description      The macro `define-action-list` defines an action list.

`uid` is a unique identifier, and must be a general Lisp object, to be compared by `equalp`. It names the list in the global registry of action lists. See `make-unregistered-action-list` to create unnamed, “unregistered” action-lists. The `uid` may be quoted, but is not required to be. It is possible, but not recommended, to define an action-list with unique identifier `nil`. If a registered action-list with the `uid` already exists (that is, one which returns `t` when compared with `equalp`), then notification and subsequent handling is controlled by the value of the variable `*handle-existing-action-list*`.

The `documentation` string allows you to provide documentation for the action list.

*sort-time* is a keyword specifying when added actions are sorted for the given list — either `:execute` or `:define-action` (see `*default-action-list-sort-time*`).

*dummy-actions* is a list of action-names that specify placeholder actions; they cannot be executed and are constrained to the order specified in this list, for example

```
'(:beginning :middle :end)
```

*default-order* specifies default ordering constraints for subsequently defined action-items where no explicit ordering constraints are specified. An example is

```
'(:after :beginning :before :end)
```

*execution-function* specifies a function that you define. It must accept arguments of the form:

*(the-action-list other-args-list &rest keyword-value-pairs)*

where the two required arguments are the action-list and a list of additional arguments passed to `execute-actions`, respectively. The remaining arguments are any number of keyword-value pairs that may be specified in the call to `execute-actions`. If no execution function is specified, then the default execution function will be used to execute the action-list.

See the manual entries for `with-action-list-mapping` and `with-action-item-error-handling` for examples of execution-functions.

To add an action to an action list you have defined, use `define-action`.

## **defsystem** *Macro*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                        |           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Summary     | <b>defsystem</b> is used to define systems for use with the Lisp-Works system tools. A system is a collection of files and other systems that, together with rules expressing the interdependencies of those files and subsystems, make a complete program. The LispWorks system tools support the development and maintenance of large programs. Find a full description at “Common Defsystem and ASDF” on page 305.                  |           |
| Package     | <b>lispworks</b>                                                                                                                                                                                                                                                                                                                                                                                                                       |           |
| Signature   | <b>defsystem name options &amp;key members rules =&gt; system-name</b>                                                                                                                                                                                                                                                                                                                                                                 |           |
| Arguments   | <p><i>name</i>           A string or a symbol, not evaluated.<br/><i>options</i>        A list of keyword-value pairs.<br/><i>members</i>       A list of strings or lists.<br/><i>rules</i>           A list.</p>                                                                                                                                                                                                                     |           |
| Values      | <i>system-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                     | A string. |
| Description | <p>The name of the system to be made is a string specified by <i>name</i>. If <i>name</i> is a symbol, then its symbol name is used.</p> <p><i>options</i> are expressed as a list of keyword-value pairs. The following keywords are recognized:</p> <p><b>:package</b>       The default package that files are compiled and loaded in. If not specified, this defaults to the value of <b>*package*</b> at macroexpansion time.</p> |           |

**:default-pathname**

Used to compute a default pathname in which to find files. `defsystem` uses `current-pathname` to compute the pathname. `defsystem` checks that all the files given as members actually exist.

**:default-host** The root pathname of a system is defined to be the `:default-host` if it is given. Otherwise, it is taken to be the directory containing the defsystem file.

Absolute pathnames are interpreted literally, and relative pathnames are taken relative to the root pathname.

**:default-type** This is the default type of the members of the system. This may be `:lisp-file`, `:lsp-file`, `:c-file`, or `:system`.

The corba module adds `:idl-file`, `:idl-client-definition`, `:idl-client-definition-only`, `:idl-server-definition` and `:idl-server-definition-only`.

The com module adds the type `:midl-file` and the automation module adds `:midl-type-library-file`.

The default is `:lisp-file`, which means files with file type (extension) "lisp".

**:documentation** This is a string.

**:object-pathname**

A string or pathname specifying a directory where object files are written.

**Note:** This option will not work if the names in `members` represent absolute pathnames.

**:optimize** A declaration specifying default compilation qualities within the scope of `compile-system`. These settings override the current global setting. They can be overridden per member by the `:optimize` option (for subsystems) or `proclaim` (in files). The `:optimize defsystem` option accepts the same optimize qualities as `proclaim` and which are fully described in “Compiler control” on page 104. See below for examples.

*members* is a list defining the members of the system. Elements of the list may be a string *name* representing the name of the physical file or system referred to. Elements of the list may also be a symbol, which is interpreted as its symbol name.

Elements of the *members* list can also be a list of the form `(name {keyword value}*)` where *name* is once again a string or a symbol naming a file or system.

The members of the system *name* must have unique names, as compared by `equalp`. For example, if *members* contains `"foo"` then there cannot be another member (either a file or a system) named `"foo"`, `"FOO"` or `foo`.

The possible keywords and their values are:

**:type** The type of this member. Allowed values are as for `:default-type`. If not specified it defaults to the value of `:default-type` given as an *option*.

**:root-module** If `nil` then this member is not loaded unless its loading is specifically requested as a result of a dependency on another module

**:source-only** Only the source file for this member is ever loaded

|                               |                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:load-only</b>             | The member is never compiled by <code>defsys-tem</code> , objects are loaded in preference to source files                                                                                                                                                                                                                                                                                  |
| <b>:load-for-compile-only</b> | The member is only loaded as necessary during compilation and is never loaded independently                                                                                                                                                                                                                                                                                                 |
| <b>:features</b>              | The member is only considered during planning if the feature expression is true.                                                                                                                                                                                                                                                                                                            |
| <b>:package</b>               | A default package for the member.                                                                                                                                                                                                                                                                                                                                                           |
| <b>:embedded-module</b>       | Only allowed when the value for <code>:type</code> is <code>:c-file</code> . The value <i>embedded-module</i> is used to create a FLI embedded module named <i>embedded-module</i> instead of loading the object file. See <code>fli:install-embedded-module</code> in the <i>LispWorks Foreign Language Interface User Guide and Reference Manual</i> for how to load the embedded module. |

On Windows, the automation module adds the keyword `:com` for a member with type `:midl-type-library-file`. Then a member of the form

```
("mso97.tlb" :type :midl-type-library-file :com nil)
```

can be specified when you use only Automation client code, reducing the memory used.

*rules* is a list of rules of the following format :

```
({:in-order-to} action {:all | ({ member-name }* )}
  (:caused-by {(action {:previous | {member-name }* }) }* )
  (:requires {(action {:previous | { member-name }* }) }*))
```

The keyword `:all` refers to all the members of the system. It provides a shorthand for specifying that a rule should apply to all the system's members. The keyword `:previous` refers

to all the members of the system that are before the member in the list of members. This makes it easy, for example, to specify that in order to compile a file in a system, all the members that come before it must be loaded.

The name of the system is returned.

There are more details about the rules in “DEFSYSTEM rules” on page 308.

## Examples

```
(defsystem defsys-macros
  (:default-pathname "/usr/users/james/scm/defsys/"
    :default-type :lisp-file
    :package defsystem)
  :members ("new-macros"
            "scm-timemacros"))

(defsystem clos-sys
  (:default-pathname "/usr/users/clc/defsys/"
    :default-type :lisp-file
    :package defsystem)
  :members
  ((("defsys-macros" :type :system :root-module nil)
    "class"
    "time-methods"
    ("scm-pathname" :source-only t)
    "execute-plan"
    "file-types"
    "make-system"
    "conv-defsys"))
  :rules
  ((:in-order-to :compile ("class" "time-methods")
    (:caused-by (:compile "defsys-macros"))
    (:requires
      (:load "defsys-macros")))
   (:in-order-to :compile
     ("time-methods" "execute-plan")
     (:requires (:load "class")))))
```

```
(defsystem dataworks-demo
  (:default-type :system)
  :members (
    "db-class"
    "planar"
    "dataworks-dep"
    "dataworks-interface-tk"
    "dataworks-interface-tools"
    "drugs-demo"
    ("gen-demo" :type :lisp-file)
    ("load-icon" :type :lisp-file :source-only t)
  )
  :rules ((:in-order-to :compile :all
  (:requires (:load :previous)))))
```

This example illustrates the use of `:optimize`.

```
(defsystem foo (:optimize ((speed 3) (space 3)
                           (safety 0)))
  :members ("bar"
            "baz")
  :rules ((:compile :all
  (:requires (:load :previous)))))
```

This last example illustrates the use of `:embedded-module`.

```
(defsystem my-foreign-code ()
  :members
  (("my-c-code.c" :type :c-file
    :embedded-module my-module)))
```

Then initialize at run time with

```
(fli:install-embedded-module 'my-module)
```

#### Notes

1. Subsystems must be defined before any system of which they are part.
2. The order of *members* is important and reflects the order in which operations are carried out on the members of the system, subject to the *rules*.

| Description | <p>The function <code>delete-directory</code> attempts to delete the directory <i>directory</i>. It returns <code>t</code> on success, and on failure either returns <code>nil</code> or signals an error.</p> <p><i>error</i> determines what happens when <code>delete-directory</code> fails. When <i>error</i> is <code>nil</code> (the default), if <i>directory</i> does not exist <code>delete-directory</code> returns <code>nil</code>, otherwise any failure causes an error to be signaled. If <i>error</i> is <code>:no-error</code>, <code>delete-directory</code> returns <code>nil</code> on any failure. If <i>error</i> is <code>:error</code>, any failure causes an error to be signaled.</p> <p>Typical reasons for failures in <code>delete-directory</code> are that <i>directory</i> is not empty, or that the user does not have the right permissions.</p> |

| <b>*describe-length*</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                 | <i>Variable</i> |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                  | Determines how many attributes of a composite object are described.                                                                                                                                                                                                                                                                                                                                                             |                 |
| Package                  | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                          |                 |
| Initial value            | 20                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |
| Description              | The variable <code>*describe-length*</code> controls how many attributes of a composite object the function <code>describe</code> describes.<br><br>This means the number of elements of a sequence, entries in a hash table, slots of a structure instance, and so on.<br><br>If <code>*describe-length*</code> is <code>nil</code> then <code>describe</code> describes all of the attributes. Use this value only with care. |                 |
| Notes                    | The <code>describe</code> functionality is load-on-demand in the Lisp-Works image as shipped. Therefore if you have not done <code>(require "describe")</code> or called <code>describe</code> , <code>*describe-length*</code> may be unbound.                                                                                                                                                                                 |                 |
| See also                 | <code>describe</code>                                                                                                                                                                                                                                                                                                                                                                                                           |                 |

| <b>*describe-level*</b> |                                                                                            | <i>Variable</i> |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The variable <code>*describe-level*</code> controls the depth to which the function <code>describe</code> describes arrays, structures and conses.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Notes       | The <code>describe</code> functionality is load-on-demand in the Lisp-Works image as shipped. Therefore if you have not do <code>(require "describe")</code> or called <code>describe</code> , <code>*describe-level*</code> may be unbound.                                                                                                                                                                                                                                                                                                                |
| Example     | <pre>CL-USER 23 &gt; (describe 1) [... load output not shown ...]  1 is a BIT DECIMAL      1 HEX          1 OCTAL        1 BINARY       1  CL-USER 24 &gt; *describe-level* 1  CL-USER 25 &gt; (defstruct foo a s d) FOO  CL-USER 26 &gt; (defmethod describe-object ((f foo) (s stream))                (format s "FOO ~S~%" f)                (describe (foo-a f) s)) #&lt;STANDARD-METHOD DESCRIBE-OBJECT NIL (FOO STREAM) 2068295C&gt;  CL-USER 27 &gt; (describe (make-foo :a (vector 1 2 3) :s 42))  FOO #S(FOO A #(1 2 3) S 42 D NIL) #(1 2 3)</pre> |

To make `describe` operate on objects inside the structure instance, increase the value of `*describe-level*`:

```
CL-USER 28 > (setf *describe-level* 2)
2

CL-USER 29 > (describe (make-foo :a (vector 1 2 3) :s
42))

FOO #S(FOO A #(1 2 3) S 42 D NIL)
#(1 2 3) is a SIMPLE-VECTOR
  0      1
  1      2
  2      3
```

### **\*describe-print-length\*** *Variable*

Summary      Specifies a print length for **describe** and **apropos**.

Package      **lispworks**

Initial value      10

Description      If **\*print-length\*** is nil, **describe** and **apropos** bind **\*print-length\*** to the value of **\*describe-print-length\***.

See also      **describe**

### **\*describe-print-level\*** *Variable*

Summary      Specifies a print level for **describe** and **apropos**.

Package      **lispworks**

Initial value      10

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Makes a LispWorks dynamic library quit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>dll-quit &amp;key kill-all-processes timeout output force =&gt; result, quit-output</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Arguments   | <p><i>kill-all-processes</i> A generalized boolean.</p> <p><i>timeout</i> A positive integer or <code>nil</code>.</p> <p><i>output</i> An output stream designator.</p> <p><i>force</i> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <p><i>result</i> <code>t</code> or <code>nil</code>.</p> <p><i>quit-output</i> A string or <code>nil</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description | <p>The function <code>dll-quit</code> makes a LispWorks dynamic library (or DLL) quit on returning from the callback in which it was called. It must be called only:</p> <ul style="list-style-type: none"><li>• In an image running as a dynamic library, meaning an image created by <code>save-image</code> with <code>:dll-exports</code> or by <code>deliver</code> with <code>:dll-exports</code>, and</li><li>• Inside the dynamic scope of a callback into the dynamic library. That is, not in a process that was started by <code>process-run-function</code>.</li></ul> <p><code>dll-quit</code> sets up the internal state such that just before returning into its caller in the LispWorks dynamic library it</p> |

causes LispWorks to quit. After quitting the callback returns as normal. The library can be unloaded using `FreeLibrary`, or you can re-use it (without re-loading).

By default `kill-all-processes` is `nil` which means that, if there are other running processes, `dll-quit` just returns `nil`. If `kill-all-processes` is non-`nil`, `dll-quit` tries to kill all the other processes, and if it succeeds, it quits.

If `kill-all-processes` is true, `timeout` is a maximum time to wait after killing the other processes. It allows `timeout` seconds for all processes to die.

`dll-quit` should be called when no other processes are running, whether they were created by a callback or by `process-run-function`. If such processes exist, by default `dll-quit` does nothing and returns `nil`. If `force` is non-`nil`, `dll-quit` always tries to set LispWorks up for quitting. LispWorks will quit even after a failure to kill all other processes and complete any required shut down operations. A true value of `force` automatically implies `kill-all-processes` true. However, if any of the other processes is stuck in a foreign call, the quitting may fail to finish properly. The default value of `force` is `nil`.

If `output` is supplied, `dll-quit` generates output if it is called when other processes are still running, or a required shut down operation was not completed. `output` can be an output stream, `t` (interpreted as `*standard-output*`) or `nil`. If `output` is `nil`, `dll-quit` collects the output and returns it as second argument `quit-output`. Otherwise it writes the output to the stream and `quit-output` is `nil`.

The output contains a list of the other processes that are still running. If `kill-all-processes` or `force` was supplied, and killing the other processes failed, the output also contains backtraces of the other processes, and possibly other debugging information.

*result* is `t` on success: the LispWorks dynamic library is set to quit on returning from the callback. *result* is `nil` when other processes are running: the image is not set to quit.

*quit-output* contains the output which was generated when *output nil* was passed. Otherwise *quit-output* is `nil`.

If `dll-quit` is called inside a recursive foreign callback, the LispWorks dynamic library quits only when the outermost callback returns.

#### Notes

1. `dll-quit` is intended for use when a LispWorks dynamic library is loaded by a main process which you (the LispWorks programmer) do not control. If you control the main process, then use `QuitLispWorks` instead.

It is expected that the main process will call into the dynamic library with some "shutdown" call, and then calls `FreeLibrary` to free the library. The shutdown call should close and free everything that needs to be closed or freed, call `dll-quit`, and return.

2. `dll-quit` is supported only where LispWorks can be a dynamic library. Currently this is in LispWorks on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD.

|-------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>list</i>   | A list.                                                                                                                                                                                                                                                       |
| Value       | <i>result</i> | An integer.                                                                                                                                                                                                                                                   |
| Description |               | The function <code>dotted-list-length</code> performs the same action as <code>list-length</code> , except that if the last <code>cdr</code> is not <code>nil</code> then instead of signaling an error, it returns the number of <code>conses</code> plus 1. |

| Summary       | Controls direct entry into the Debugger tool.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Package       | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description   | <p>The variable <code>*enter-debugger-directly*</code> is a generalized boolean which affects the behavior of the LispWorks IDE when an error is signaled outside of the Listener REPL.</p> <p>Value <code>nil</code> causes an error notifier window to be displayed (from which you can abort, report a bug, or raise a Debugger tool).</p> <p>A true value causes the Debugger tool to be displayed immediately, and no error notifier appears.</p> |
| Notes         | Errors signaled in a Listener Read-Eval-Print loop are handled in the REPL and therefore <code>*enter-debugger-directly*</code> has no effect on the behavior in this case.                                                                                                                                                                                                                                                                            |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Reads the value of an environment variable from the environment table of the calling process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Signature   | <code>environment-variable name =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Arguments   | <code>name</code> A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | <code>result</code> A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description | <p>The function <code>environment-variable</code> reads the environment variable specified by <code>name</code> and returns its value, or <code>nil</code> if the variable could not be found.</p> <p>A <code>setf</code> method is also defined, allowing you to set the value of an environment variable:</p> <pre>(setf (environment-variable name) value)</pre> <p>If <code>value</code> is a string, then <code>name</code> is set to be <code>value</code>. If <code>value</code> is <code>nil</code> then <code>name</code> is removed from the environment table.</p>                              |
| Example     | In this first example the value of the environment variable <code>PATH</code> is returned:<br><br><pre>(environment-variable "PATH")</pre> <p>The result is a string of all the defined paths:</p><br><pre>"c:\\hqbin\\nt\\x86;c:\\hqbin\\nt\\x86\\perl;c:\\hqbin\\\nwin32;c:\\usr\\local\\bin;C:\\WINNT35\\system32;C:\\WINNT35;;C:\\MSTOOLS\\bin;C:\\TGS3D\\PROGRAM;c:\\program\nfiles\\devstudio\\sharedide\\bin\\ide;c:\\program\nfiles\\devstudio\\sharedide\\bin;c:\\program\nfiles\\devstudio\\vc\\bin;c:\\msdev\\bin;C:\\WINDOWS;C:\\WINDOWS\\COMMAND;C:\\WIN95\\COMMAND;C:\\MSINPUT\\MOUSE"</pre> |

In the second example, the variable **MYTZONE** is found not to be in the environment table:

```
(environment-variable "MYTZONE")
```

```
NIL
```

It is set to be **GMT** using the **setf** method:

```
(setf (environment-variable "MYTZONE") "GMT")
```

|--------------------|-----------------|
| <b>errno-value</b> | <i>Function</i> |
|--------------------|-----------------|

Summary Returns the current value of the UNIX variable **errno**.

Package **lispworks**

Signature **errno-value => value**

Arguments None.

Values **value** The current value of **errno**.

Description The function **errno-value** returns the current value of the UNIX variable **errno**.

Notes **errno-value** is implemented only on non-Windows platforms.

Example **USER 10 > (errno-value)**  
2

```
USER 11 > (get-unix-error 2)
"no such file or directory"
```

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns a path in the <code>examples</code> folder.                                                                                                                                                                 |
| Package     | <code>lispworks</code>                                                                                                                                                                                              |
| Signature   | <code>example-file file =&gt; path</code>                                                                                                                                                                           |
| Arguments   | <code>file</code> A pathname designator.                                                                                                                                                                            |
| Values      | <code>path</code> A pathname.                                                                                                                                                                                       |
| Description | The function <code>example-file</code> returns an absolute path to a file <i>file</i> in the <code>examples</code> folder of the LispWorks library.<br><br>It does not actually test for the existence of the file. |
| Example     | <pre>(example-file "capi/applications/othello.lisp") =&gt; #P"C:/Program Files/LispWorks/lib/7-1-0- 0/examples/capi/applications/othello.lisp"</pre>                                                                |
| See also    | <code>example-compile-file</code><br><code>example-edit-file</code>                                                                                                                                                 |

|           | <i>Function</i>                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| Summary   | Compiles a file in the <code>examples</code> folder to a temporary output file.                                   |
| Package   | <code>lispworks</code>                                                                                            |
| Signature | <code>example-compile-file file &amp;rest args =&gt; output-truename, warnings-p, failure-p</code>                |
| Arguments | <code>file</code> A pathname designator.<br><br><code>args</code> Arguments passed to <code>compile-file</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>output-truename</i> A pathname or <code>nil</code> .<br><i>warnings-p</i> A generalized boolean.<br><i>failure-p</i> A generalized boolean.                                                                                                                                                                                                                                                                                                             |
| Description | The function <code>example-compile-file</code> constructs the path to <i>file</i> in the <code>examples</code> folder of the LispWorks library, and a path to an output file in a temporary location which is likely to be writable.<br><br>It then calls <code>compile-file</code> with these paths as the <i>input-file</i> and <i>output-file</i> , also passing the other <i>args</i> , and returns the values returned by <code>compile-file</code> . |
| See also    | <code>get-temp-directory</code><br><code>example-file</code><br><code>example-edit-file</code>                                                                                                                                                                                                                                                                                                                                                             |

| Arguments                                                                   | <i>file</i> A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                      |
| Description                                                                 | The function <code>example-edit-file</code> constructs the path to the file <i>file</i> in the examples folder of the LispWorks library, adding the "lisp" extension if no extension is specified, and opens the file in an Editor tool in the LispWorks IDE.<br><br>If <i>file</i> is a directory name (ending in a slash), then the list of files with "lisp" extension in that directory is displayed in the Editor. |

Examples      This form displays the file `lib/7-1-0-0/examples/capi/applications/othello.lisp` from the Lisp-Works library:

```
(example-edit-file "capi/applications/othello")
```

## **example-load-binary-file** *Function*

Summary      Loads a fasl file compiled by `example-compile-file`.

Package      `lispworks`

Signature      `example-load-binary-file file => result`

Arguments      `file`      A pathname designator.

Values      `result`      A generalized boolean.

Description      The function `example-load-binary-file` constructs the path to an output file in a temporary location which would be used as the *output-file* by `example-compile-file`.

It then calls `load` on that path, and returns the value *result* returned by `load`.

## **execute-actions** *Macro*

Summary      Executes in sequence the actions on a given list.

Package      `lispworks`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Arguments   | <p><i>name-or-list</i>      An action list</p> <p><i>keyword-value-pairs</i></p> <p style="text-align: center;">See description.</p> <p><i>other-args</i>      A list.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description | <p>The macro <code>execute-actions</code> executes, in sequence, the actions on the specified list. If the action-list specified by <i>name-or-list</i> does not exist, then this is handled according to the value of <code>*handle-missing-action-list*</code>. Note that <i>name-or-list</i> is evaluated.</p> <p>If a user-defined execution function was specified when the action list was defined, then it should accept the following arguments:</p> <p style="padding-left: 40px;"><code>(<i>action-list</i> <i>other-args</i> &amp;rest <i>keyword-value-pairs</i>)</code></p> <p>Note that <i>other-args</i> is passed as a single list.</p> <p>If a user-defined execution function was not specified when the action list was defined, then the following default mapping occurs. Each action's data is invoked via apply on <i>other-args</i>:</p> <p style="padding-left: 40px;"><code>(apply <i>data</i> <i>other-args</i>)</code></p> <p>This behavior is modified by the keyword-value-pairs, thus:</p> <ul style="list-style-type: none"> <li>• If the keyword parameter <code>:ignore-errors-p</code> is non-nil, any otherwise-unhandled errors signaled inside the execution of that function will be trapped, and a warning issued. Execution continues with the next action-item. If <code>:ignore-errors-p</code> is nil (or not specified), then the error is not trapped.</li> </ul> |

- If the keyword parameter `:post-process` is non-nil, the first value returned by each action is handled, according to `:post-process`, thus:

|                       |                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>:collect</code> | collect values into list                                                                                                           |
| <code>:and</code>     | return <code>t</code> only if all values are <code>t</code> . Return <code>nil</code> immediately if any value is <code>nil</code> |
| <code>:or</code>      | return first non-nil value                                                                                                         |

## \*external-formats\*

## **Variable**

**Summary** A list of the names of the defined external formats.

## Package lispworks

Initial value Microsoft Windows platforms:

```
(WIN32:CODE-PAGE FLI::UNICODE-WCHAR FLI::LATIN-1-WCHAR  
FLI:ASCII-WCHAR :KOI8-R :MACOS-ROMAN :UTF-32 :UTF-32BE  
:UTF-32LE :UTF-32-REVERSED :UTF-32-NATIVE :UTF-16 :UTF-  
16BE :UTF-16LE :UTF-16-REVERSED :UTF-16-NATIVE :UTF-8  
:GBK :WINDOWS-CP936 EXTERNAL-FORMAT:DOUBLE-BYTE-TABLE-  
LOOKUP :JIS :EUC-JP :SJIS :LATIN-1-TERMINAL :BMP  
:UNICODE :LATIN-1-SAFE :LATIN-1-CHECKED :LATIN-1 :EUC  
:SHIFT-JIS :NIHONGO-MS :NIHONGO-EUC :NIHONGO-JIS  
CHARACTER :BMP-REVERSED :BMP-NATIVE EXTERNAL-  
FORMAT::RAW-BASE-CHARACTER :ASCII-TERMINAL :ASCII)
```

On all other platforms:

```
(FLI::UNICODE-WCHAR FLI::LATIN-1-WCHAR FLI:ASCII-WCHAR  
:KOI8-R :MACOS-ROMAN :UTF-32 :UTF-32BE :UTF-32LE :UTF-  
32-REVERSED :UTF-32-NATIVE :UTF-16 :UTF-16BE :UTF-16LE  
:UTF-16-REVERSED :UTF-16-NATIVE :UTF-8 :GBK :WINDOWS-  
CP936 EXTERNAL-FORMAT:DOUBLE-BYTE-TABLE-LOOKUP :JIS  
:EUC-JP :SJIS :LATIN-1-TERMINAL :BMP :UNICODE :LATIN-1-  
SAFE :LATIN-1-CHECKED :LATIN-1 :EUC :SHIFT-JIS  
:NIHONGO-MS :NIHONGO-EUC :NIHONGO-JIS EXTERNAL-  
FORMAT::HOST-PORTABLE EXTERNAL-FORMAT::LATIN-PORTABLE  
CHARACTER :BMP-REVERSED :BMP-NATIVE EXTERNAL-  
FORMAT::RAW-BASE-CHARACTER :ASCII-TERMINAL :ASCII)
```

**Description** The variable **\*external-formats\*** contains a list of the names of the defined external formats.

The platform-specific external format names are:

## code-page

Uses the encoding in the Microsoft Windows code page specified by the :id parameter.

**latin-portable**

Intended for use when communicating with X servers, for example when passing XLFD names. Uses the X Portable Character Set.

**host-portable**

A synonym for **latin-portable**.

**false** *Function*

Summary      Ignores its arguments and returns **nil**.

Package      **lispworks**

Signature      **false &rest ignore => nil**

Arguments      *ignore*      All arguments are ignored.

Value      **nil**

Description      The function **false** takes any number of arguments, which it ignores, and returns **nil**. It is useful as a functional argument.

See also      **do-nothing**  
**true**

**file-directory-p** *Function*

Summary      Tests for the presence of a directory.

Package      **lispworks**

|             |                                                                                                      |                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>file-directory-p pathname =&gt; bool</code>                                                    |                                                                                                                                                          |
| Arguments   | <i>pathname</i>                                                                                      | A pathname, string, or file-stream.                                                                                                                      |
| Values      | <i>bool</i>                                                                                          | If <i>t</i> , the pathname represented by <i>pathname</i> exists and is a directory. If <i>nil</i> , it either does not exist, or it is not a directory. |
| Description | <code>file-directory-p</code> tests whether the pathname represents a directory.                     |                                                                                                                                                          |
| Example     | <pre>CL-USER 70 &gt; (file-directory-p "~") T  CL-USER 71 &gt; (file-directory-p ".login") NIL</pre> |                                                                                                                                                          |

|           |                                                                                                                                                                                                                                                                                                                                                               | <i>Function</i> |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary   | Matches a regular expression.                                                                                                                                                                                                                                                                                                                                 |                 |

|             | <i>brackets-limits-vector</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A vector.                                    |  |
| Description | <p>The function <code>find-regexp-in-string</code> searches the string <i>string</i> for a match for the regular expression <i>pattern</i>. The index in <i>string</i> of the start of the first match is returned in <i>pos</i>, and the length of the match is <i>len</i>.</p> <p>If <i>from-end</i> is <code>nil</code> (the default value) then the search starts at index <i>start</i> and ends at index <i>end</i>. <i>start</i> defaults to 0 and <i>end</i> defaults to <code>nil</code>. If <i>from-end</i> is true, then the search direction is reversed.</p> <p><i>pattern</i> should be a precompiled regular expression object or a string. If <i>pattern</i> is a string then <code>find-regexp-in-string</code> first makes a precompiled regular expression object. This operation allocates, therefore if you need to repeatedly call <code>find-regexp-in-string</code> with the same pattern, it is better to call <code>precompile-regexp</code> once and pass its result, a pre-compiled regular expression object, as <i>pattern</i>.</p> <p><i>case-sensitive</i> controls whether a string <i>pattern</i> is precompiled as a case sensitive or case insensitive search. A non-nil value means a case sensitive search. The value <code>nil</code> (the default) means a case insensitive search. <i>case-sensitive</i> is ignored if <i>pattern</i> is not a string.</p> <p>When <i>brackets-limits</i> is non-nil, a successful call to <code>find-regexp-in-string</code> returns a third value which is a vector specifying the limits of matches of any pair of <code>\(</code> and <code>\)</code> in the search pattern. The length of the vector is twice the number of pairs, and the elements are offsets from the beginning of the match of the whole pattern. Each pair of <code>\(</code> and <code>\)</code> is assigned a number in the order of the appearance of the <code>\(</code> in the pattern. This number multiplied by two is the index into the vector where the match for this pair starts, and the next</p> |                                              |  |

element specifies the end of the match. The default value of *brackets-limits* is `nil`.

The regular expression syntax used by `find-regexp-in-string` is similar to that used by Emacs, as described in the "Regular expression syntax" section of the *LispWorks Editor User Guide*. (If you use **Help > Search** to locate this section, select the **Contents** radio button.)

**Example**

This form allocates several regular expression objects:

```
(loop with pos = 0
      with len = 0
      while pos
      do (multiple-value-setq (pos len)
                               (find-regexp-in-string "[0,2,4,6,8]"
   "0123456789"
   :start (+ pos len)))
         when pos
         do (format t "~&Match at pos ~D len ~D~%" pos len))
```

This form does the same matching but allocates just one pre-compiled regular expression object:

```
(loop with pattern = (precompile-regexp "[0,2,4,6,8]")
      with pos = 0
      with len = 0
      while pos
      do (multiple-value-setq (pos len)
                               (find-regexp-in-string pattern "0123456789"
   :start (+ pos len)))
         when pos do (format t "~&Match at pos ~D len ~D~%" pos len))
```

|             | <i>error-p</i>                                                                                                                                                                                                                                                                                                                             | A boolean.                  |
| Values      | <i>args</i>                                                                                                                                                                                                                                                                                                                                | A list, or the symbol :none |
| Description | <p><i>function</i> is the function whose arguments are required</p> <p>If <i>error-p</i> is nil, then <code>function-lambda-list</code> returns :none if <i>function</i> is not defined, and does not start the debugger. The default value of <i>error-p</i> is t, meaning that an error is signaled if <i>function</i> is undefined.</p> |                             |
| Example     | <pre>TEST 2 &gt; (function-lambda-list 'editor:create-buffer-command) (EDITOR::P &amp;OPTIONAL EDITOR:BUFFER-NAME)</pre>                                                                                                                                                                                                                   |                             |

## get-inspector-values sort-inspector-p

### Generic Functions

|           |                                                                                                               |                             |
|-----------|---------------------------------------------------------------------------------------------------------------|-----------------------------|
| Summary   | Customizes the information displayed and sort order of attributes/values in the LispWorks IDE Inspector tool. |                             |

| Description | <p>The generic functions <code>get-inspector-values</code> and <code>sort-inspector-p</code> allow you to customize the LispWorks IDE Inspector tool by adding new ways to display class instances and control sorting of the attributes and values.</p> <p><code>get-inspector-values</code> allows you to add new formats (corresponding to different values of mode) in which instances of a particular class can be inspected. Mode <code>nil</code> is the default mode, which is always present (it can be overwritten).</p> <p>LispWorks includes methods for:</p> <pre>(get-inspector-values (object nil)) (get-inspector-values (standard-object nil)) (get-inspector-values (structured-object nil)) (get-inspector-values (sequence nil)) (get-inspector-values cons nil))</pre> <p>and so on.</p> <p><code>sort-inspector-p</code> determines whether to sort the list of displayed attributes/values.</p> <p>The Inspector tool calls <code>sort-inspector-p</code> with the current object and mode the first time it displays this object in this mode to determine whether to sort the list of attributes/values. If it returns non-nil, it sorts by item, otherwise it does not sort.</p> |                                                                                                                  |

There are various methods on system-defined types to get the most useful behavior. You can add methods for your own types.

- Notes      The sort type can be changed interactively in the Inspector tool by using the the **Preferences...** dialog.
- Example    This example allows inspection of a CLOS object, displaying only direct slots from a chosen class in its class precedence list. This can be useful when an object inherits many slots from superclasses, and the inherited slots are of no interest.

```

(defmethod lispworks:get-inspector-values
  ((object standard-object)
   (mode (eql 'direct-as)))
  (declare (ignore mode))
  (loop with object-class =
        (class-of object)
        with precedence-list =
        (class-precedence-list object-class)
        with items =
        (loop for super in precedence-list
              collecting (list*
                           (format nil "~a"
                                   (class-name super))
                           super)))
        with class =
        (or (capi:prompt-with-list items
                                    "Direct slots as ...")
            object-class)
            ;; default if no selection
        with slots =
        (class-direct-slots class)
        for slot in slots
        for name =
        (clos::slot-definition-name slot)
        collect name into names
        collect (if (slot-boundp object name)
                   (slot-value object name)
                   :slot-unbound)
        into values
        finally
        (return
         (values
          names
          values
          nil
          #'(lambda
              (x slot-name index new-value)
              (declare (ignore index))
              (setf (slot-value x slot-name)
                    new-value))
          (format nil "~a - direct slots as ~a"
                  (class-name object-class)
                  (class-name class)))))))

```

|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package               | <code>lispworks</code>                                                                                                                                                                              |
| Summary               | Determines the search utility used by <code>Grep</code> searches in the Search Files tool in the LispWorks IDE.                                                                                     |
| Initial value         | <code>"grep"</code> on non-Windows platforms.<br><code>nil</code> on Windows.                                                                                                                       |
| Description           | If the value is a string, it is the search utility to run in the Search Files tool.<br><br>If the value is <code>nil</code> , then the value of<br><br><code>(sys:lispworks-file "etc/grep")</code> |

is expected to be an executable, which is run. On Windows a suitable `grep.exe` is included with LispWorks in this location.

The search utility is passed arguments constructed using `*grep-command-format*` and `*grep-fixed-args*`.

See the *LispWorks IDE User Guide* for more information about the Search Files tool.

\*qgrep-fixed-args\*

**\*grep-command-format\*** *Variable*

## Package lispworks

**Summary** The format string used to construct the arguments passed to the Search Files tool to perform a **Grep** search.

Initial value "cd '~a'; ~a ~a ~a /dev/null" on non-Windows platforms.

"~a ~a ~a NUL" on Windows.

Description On non-Windows platforms, the first format argument is the current directory.

The remainder of the format arguments are:

- the value of `*grep-command*` or, if this is `nil`, the value of `(sys:lispworks-file "etc/grep")`.
  - the value of `*grep-fixed-args*`.
  - the arguments you specify.

See the *LispWorks IDE User Guide* for more information about the Search Files tool.

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package       | <b>lispworks</b>                                                                                                                                                                                                                                                                                             |
| Summary       | Arguments added to the command string of a <b>Grep</b> search in the Search Files tool.                                                                                                                                                                                                                      |
| Initial value | " <b>-n</b> "                                                                                                                                                                                                                                                                                                |
| Description   | The variable <b>*grep-fixed-args*</b> provides arguments added to a <b>Grep</b> command string in the Search Files tool. The value should ensure that the line number is output at the start of each match.<br><br>See the <i>LispWorks IDE User Guide</i> for more information about the Search Files tool. |
| See also      | <b>*grep-command*</b><br><b>*grep-command-format*</b>                                                                                                                                                                                                                                                        |

**\*handle-existing-action-in-action-list\*** *Variable*

|               |                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Contains keywords determining behavior on exceptions raised when an action definition already exists in a given action list.                                                                                       |
| Package       | <b>lispworks</b>                                                                                                                                                                                                   |
| Initial value | ( <b>:warn :redefine</b> )                                                                                                                                                                                         |
| Description   | The variable <b>*handle-existing-action-in-action-list*</b> is a list containing one of <b>:warn</b> , or <b>:silent</b> , determining whether to notify the user, and one of <b>:skip</b> , or <b>:redefine</b> , |

to determine what to do about an action definition when the action already exists in the given action list.

It is used by `define-action`.

See also      `define-action`

**\*handle-existing-action-list\***                                    *Variable*

Summary      Contains keywords determining what to do about a given action list operation when the action list already exists.

Package      `lispworks`

Initial value      `(:warn :skip)`

Description      A list containing either `:warn` or `:silent`, determining whether to notify the user, and either `:skip` or `:redefine` to determine what to do about an action list operation when the action list already exists. The initial value is `(:warn :skip)`.

It is used by the macro `define-action-list`.

See also      `define-action-list`

**\*handle-missing-action-list\***                                    *Variable*

Summary      Defines how to handle an operation on a missing action list.

Package      `lispworks`

Signature      `*handle-missing-action-list*`

Initial value      `:error`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial value | <code>:error</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description   | <p>The variable <code>*handle-warn-on-redefinition*</code> specifies what action should be taken on defining external symbols in certain packages. It is designed to protect against (re)definition of symbols in implementation packages.</p> <p>The protected packages are those specified in the variable <code>*packages-for-warn-on-redefinition*</code>.</p> <p>If <code>*handle-warn-on-redefinition*</code> is set to <code>:warn</code> then you are warned. If it is set to <code>:quiet</code> or <code>nil</code>, the definition is done quietly. If, however, it is set to <code>:error</code>, then LispWorks signals an error.</p> |
| Notes         | <p>The checking is useful because it is relatively easy to redefine an external symbol by mistake, and it leads to undefined behavior which is difficult to debug. It is therefore a bad idea to change the value of <code>*handle-warn-on-redefinition*</code> to something else. If required, do this by rebinding <code>*handle-warn-on-redefinition*</code> rather than setting its global value.</p>                                                                                                                                                                                                                                          |

| <b>hardcopy-system</b> |                                                                              | <i>Function</i>                                                                                                         |
|------------------------|------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Summary                | Print each file of a system to a printer.                                    |                                                                                                                         |
| Package                | <code>lispworks</code>                                                       |                                                                                                                         |
| Signature              | <code>hardcopy-system system-name &amp;key command simulate =&gt; nil</code> |                                                                                                                         |
| Arguments              | <code>system-name</code>                                                     | A symbol representing the name of the system. The system must have been defined using the <code>defsystem</code> macro. |

**simulate** If `nil` or not present then `hardcopy-system` works silently. Otherwise a plan of the actions which `hardcopy-system` intends to carry out is printed. What happens next depends on the value of *simulate*:

`t` — do nothing.

`:ask` — you are asked, using `y-or-n-p`, if you want the plan to be carried out.

`:each` — `hardcopy-system` displays each action in the plan one at a time, and asks you if you want to carry out this particular action. The answer executes the rest of the plan without further prompting, `e` returns from `hardcopy-system` without further processing, and `y` and `n` work as expected.

Values      `hardcopy-system` returns `nil`.

Examples     

```
(hardcopy-system 'blackboard)
(hardcopy-system 'tms :simulate :ask :command "lpr")
```

Notes        By default, `hardcopy-system` uses `*print-command*` as the command sent to the shell.

`*print-command*`

### **\*init-file-name\*** *Variable*

Summary      The default user initialization file.

Package      `lispworks`

Initial value    `"~/.lispworks"`

Description      The variable `*init-file-name*` is the name of the default user initialization file.  
However, if the user initialization file is specified by either:

- the command line argument `-init`, or
- user preferences (as set via the Preferences dialog in the LispWorks IDE)

then the value of `*init-file-name*` is not used.

### **\*inspect-through-gui\*** *Variable*

Summary      Controls what `inspect` does in the development environment.  
Package      `lispworks`  
Initial value      `nil`  
Description      The variable `*inspect-through-gui*` controls what `inspect` does in the development environment.  
When the value is `nil`, `inspect` uses a command line interface in the REPL.  
When the value is true, `inspect` invokes an Inspector tool in the LispWorks IDE.

### **lisp-image-name** *Function*

Summary      Returns the name of the running image.  
Package      `lispworks`  
Signature      `lisp-image-name => name`

|             |                                                                                                                                                                                                                                                                                                                                          |           |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Arguments   | None.                                                                                                                                                                                                                                                                                                                                    |           |
| Values      | <i>name</i>                                                                                                                                                                                                                                                                                                                              | A string. |
| Description | The function <code>lisp-image-name</code> returns a string representing the full path to the running LispWorks image. The example below is in typical LispWorks for Windows and LispWorks for Linux installations. In resaved and delivered images (including dynamic libraries such as Windows DLLs), the appropriate path is returned. |           |
| Example     | <p>On Windows:</p> <pre>CL-USER 1 &gt; (lisp-image-name) "C:\\Program Files\\LispWorks\\lispworks-7-1-0-x86- win32.exe"</pre> <p>On Linux:</p> <pre>CL-USER 1 &gt; (lisp-image-name) "/usr/bin/lispworks-7-1-0-x86-linux"</pre>                                                                                                          |           |
| See also    | <code>*line-arguments-list*</code>                                                                                                                                                                                                                                                                                                       |           |

## **\*lispworks-directory\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The main LispWorks installation directory.                                                                                                                                                                                                                                                           |
| Package       | <code>lispworks</code>                                                                                                                                                                                                                                                                               |
| Initial value | <p>Some examples of the initial value are:</p> <pre>#P"/usr/lib/lispworks/" on SPARC Solaris.</pre> <pre>#P"/usr/local/lib/LispWorks/" on Linux (for an installation from the tar archive) x86/x64 Solaris or FreeBSD.</pre> <pre>#P"/usr/lib64/LispWorks/" on Linux (for an RPM installation)</pre> |

#P"C:\Program Files\LispWorks\" or #P"C:\Program Files (x86)\LispWorks\" on Microsoft Windows.  
#P"/Applications/LispWorks 7.1 (32-bit)/Library/"  
or #P"/Applications/LispWorks 7.1 (64-bit)/Library/" on Mac OS X.

Note however that the value can be set when configuring an image or on startup.

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The variable <b>*lispworks-directory*</b> holds the name of the directory where various files important for the running of LispWorks are located.</p> <p>When LispWorks starts in a directory which contains an appropriate numbered subdirectory such as <code>lib/7-1-0-0/</code>, then it assumes this is the LispWorks installation directory and sets <b>*lispworks-directory*</b> accordingly. Additionally, LispWorks for Macintosh running on Cocoa looks for such a subdirectory in the <code>Library</code> folder alongside its application bundle, and if found it sets <b>*lispworks-directory*</b> accordingly.</p> <p>On non-Windows platforms, LispWorks then consults the Unix environment variable <code>LISPWORKS_DIRECTORY</code>. If this is set, then <b>*lispworks-directory*</b> is set accordingly.</p> <p>The <code>lib/7-1-0-0/</code> subdirectory of <b>*lispworks-directory*</b> should include these subdirectories:</p> <ul style="list-style-type: none"><li><code>config</code>, which contains the configuration files.</li><li><code>patches</code>, which contains any public (numbered) patches that are distributed by LispWorks Ltd.</li><li><code>private-patches</code>, which is the place to put private (named) patches that are sent to you by Lisp Support.</li><li><code>postscript</code>, which contains configuration files for printing using the CAPI printing library. See “Configuring the printer” on page 189 for more information on printer configuration.</li></ul> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**examples**, which contains various files of example code.

Other directories are **etc**, **load-on-demand** and **manual**. There is also **app-defaults** for platforms where Motif is supported.

| Values                  | Returns <b>nil</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description             | <p>Loads into the image all appropriate files from the directory <b>patches</b> in the directory determined by <b>*lispworks-directory*</b>, and then loads the file <b>private-patches/load.lisp</b> where load forms for any private patches may be placed. When the appropriate patches have successfully been loaded, the updated version of the image can be saved using <b>save-image</b>.</p> <p>You should call <b>load-all-patches</b> before starting the Lisp-Works IDE. Thus, you normally place the call to this function in your <b>.lispworks</b> file.</p> <p>The system expects all patches to be loaded sequentially. If a patch is missing, there is a warning message. In this situation, it is advisable to contact Lisp Support to obtain a copy of the missing patch.</p> |

|           | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Summary   | Load each file of a system into the Lisp image if either the file has not been loaded, or the file has been written since it was last loaded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Arguments | <p><b><i>system-name</i></b> A symbol representing the name of the system. The system must have been defined using the <code>defsystem</code> macro.</p> <p><b><i>force</i></b> If <code>t</code> then all the files in the system are loaded regardless. (This argument was formerly called <code>force-p</code>. The old name is currently still accepted for compatibility.)</p> <p><b><i>simulate</i></b> If <code>nil</code> or not present then <code>load-system</code> works silently. Otherwise a plan of the actions which <code>load-system</code> intends to carry out is printed. What happens next depends on the value of <code>simulate</code>:</p> <ul style="list-style-type: none"> <li><code>t</code> — do nothing.</li> <li><code>:ask</code> — you are asked, using <code>y-or-n-p</code>, if you want to carry out the plan.</li> <li><code>:each</code> — <code>load-system</code> displays each action in the plan one at a time, and asks you if you want to carry out this particular action. The answer executes the rest of the plan without further prompting, <code>e</code> returns from <code>load-system</code> without further processing, and <code>y</code> and <code>n</code> work as expected.</li> </ul> |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>source-only</i>      | If t the source files of the system are loaded. This only applies to file types where it makes sense to load a source file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>target-directory</i> | This is the directory to search for the object files. If the object file cannot be found here then the source file from the system's default directory are loaded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Examples                | <pre>(load-system 'blackboard)  (load-system 'tms :simulate :ask :source-only t)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Notes                   | <p>For Lisp files <code>load-system</code> loads the object file (if it exists) into the image, unless over-ridden by the <code>:source-only</code> keyword argument. This behavior can be changed so that the newest file (whether source or object) is loaded by setting the variable <code>*load-source-if-newer*</code> to t.</p> <p>C source files, for example <code>foo.c</code>, can be included in a system (see the use of <code>:default-type</code> and <code>:type</code> in <code>defsystem</code>). The corresponding object file name is <code>foon.so</code> on Linux, FreeBSD, AIX and x86/x64 Solaris, <code>foon.dylib</code> on Mac OS X and <code>foon.o</code> on SPARC Solaris, where <i>n</i> is a platform-specific integer. On Windows the object file name is <code>foo.dll</code>.</p> |

**make-*mt-random-state*** *Function*

Summary      Creates an object of type `mt-random-state`.

Package      `lispworks`

Signature      `make-mt-random-state &optional state => new-state`

Arguments      `state`      `nil`, `t` or an object of type `mt-random-state`. The default is `nil`.

Values      `new-state`      A new object of type `mt-random-state`.

Description      The function `make-mt-random-state` creates a new object of type `mt-random-state` which is suitable for use as the value of `*mt-random-state*`.

If `state` is an object of type `mt-random-state`, then `new-state` is a copy of `state`. If `state` is `nil`, then `new-state` is a copy of the value of `*mt-random-state*`. If `state` is `t` then `new-state` is an object of type `mt-random-state` initialized using a call to `get-universal-time`.

`make-mt-random-state` is analogous to  
`cl:make-random-state`.

| Summary          | Returns a pseudo-random number using the Mersenne Twister algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package          | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Signature        | <code>mt-random arg &amp;optional state =&gt; random-number</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Arguments        | <p><code>arg</code> A positive <code>integer</code> or a positive <code>float</code>.</p> <p><code>state</code> An object of type <code>mt-random-state</code>. The default is the value of <code>*mt-random-state*</code>.</p>                                                                                                                                                                                                                                                                                                                                                              |
| Values           | <p><code>random-number</code> A non-negative number less than <code>arg</code> and of the same type as <code>arg</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description      | <p>The function <code>mt-random</code> returns a pseudo-random number which is non-negative, less than <code>arg</code> and is of the same type as <code>arg</code>.</p> <p><code>random-number</code> is generated using the Mersenne Twister algorithm published by Makoto Matsumoto and Takuji Nishimura at<br/> <code><a href="http://www.math.keio.ac.jp/~matumoto/emt.html">http://www.math.keio.ac.jp/~matumoto/emt.html</a></code>.</p> <p>We thank the authors for making the algorithm freely available.</p> <p><code>mt-random</code> is analogous to <code>cl:random</code>.</p> |

## **mt-random-state** *Type*

|             |                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The type of objects containing state information used by <code>mt-random</code> .                                                                                                                                   |
| Package     | <code>lispworks</code>                                                                                                                                                                                              |
| Description | The Mersenne Twister pseudo-random number generator uses state data contained in a object of type <code>mt-random-state</code> .<br><br><code>mt-random-state</code> is analogous to <code>cl:random-state</code> . |
| See also    | <code>*mt-random-state*</code><br><code>mt-random</code><br><code>mt-random-state-p</code>                                                                                                                          |

## **mt-random-state-p** *Function*

|           |                                                                  |
|-----------|------------------------------------------------------------------|
| Summary   | The predicate for objects of type <code>mt-random-state</code> . |
| Package   | <code>lispworks</code>                                           |
| Signature | <code>mt-random-state-p arg =&gt; result</code>                  |

|             |               |                                                                                                                                                                                                                                                             |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>arg</i>    | An object.                                                                                                                                                                                                                                                  |
| Values      | <i>result</i> | A boolean.                                                                                                                                                                                                                                                  |
| Description |               | The function <code>mt-random-state-p</code> returns <code>t</code> if <i>arg</i> is an object of type <code>mt-random-state</code> , and <code>nil</code> otherwise.<br><br><code>mt-random-state-p</code> is analogous to <code>cl:random-state-p</code> . |
| See also    |               | <code>mt-random-state</code>                                                                                                                                                                                                                                |

## pathname-location

*Function*

|             |                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the location of a file.                                                                                                                                                                                                              |
| Signature   | <code>pathname-location pathname =&gt; location</code>                                                                                                                                                                                       |
| Arguments   | <i>pathname</i> A pathname designator.                                                                                                                                                                                                       |
| Values      | <i>location</i> A pathname.                                                                                                                                                                                                                  |
| Description | The function <code>pathname-location</code> returns a pathname <i>location</i> that represents the directory where the file <i>pathname</i> resides. Each of the name, type and version components of <i>location</i> are <code>nil</code> . |

|         |                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | Due to the ANSI Common Lisp definition of the <code>directory</code> function and the fact that LispWorks returns fully specified truenames, the form |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

```
(directory (truename "/tmp/"))
```

will always signal an error or return the list `(#P"/tmp/")`. To obtain the contents of the `/tmp` directory, use the form

```
(directory (pathname-location (truename "/tmp/")))
```

| Values            | <code>pattern</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A precompiled regular expression object.                                      |
|                   | <code>condition-designators</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | - A list.                                                                     |
| Description       | <p>The function <code>precompile-regexp</code> returns a precompiled regular expression object suitable for passing as <code>pattern</code> to functions like <code>find-regexp-in-string</code>.</p> <p><code>case-sensitive</code> controls whether <code>string</code> is precompiled as a case sensitive or case insensitive search. A non-<code>nil</code> value means a case sensitive pattern. The value <code>nil</code> (the default) means a case insensitive pattern.</p> <p><code>error-function</code> is used when the string is not a legal regular expression. In this case, if <code>error-function</code> is not <code>nil</code>, it is applied to a list of arguments which are designators for a condition like the arguments that <code>error</code> takes. If <code>error-function</code> is <code>nil</code>, <code>precompile-regexp</code> returns <code>nil</code> as the first argument and the list of arguments as a second return value, <code>condition-designators</code>. <code>error-function</code> defaults to <code>error</code>.</p> |                                                                               |

Notes For the regular expression syntax, see `find-regexp-in-string`.

## **print-actions** *Function*

Summary Prints a listing of the action items on a given action list in order.

Package `lispworks`

Signature `print-actions name-or-list &optional stream`

Arguments `name-or-list` An action list.  
`stream` An output stream.

Description The function `print-actions` prints a listing of the action items on the action-list denoted by `name-or-list`, in order.

If the action-list specified by `name-or-list` does not exist, then this is handled according to the value of `*handle-missing-action-list*`.

The output is written to the stream `stream`. The default value of `stream` is the value of `*standard-output*`.

See also `print-action-lists`

## **print-action-lists** *Function*

Summary Prints a list of all the action lists in the global registry.

|         |                                                            |
|---------|------------------------------------------------------------|
| Summary | Controls the package prefix used when a symbol is printed. |
| Package | <b>lispworks</b>                                           |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description   | <p>The variable <code>*print-nickname*</code> controls which package prefix is used when a symbol is printed and the symbol's package needs to be output.</p> <p>If <code>*print-nickname*</code> is true and the package has at least one nickname, then the first of the nicknames (that is, the first nickname in the list returned by <code>package-nicknames</code>) is output. Otherwise, the package name is output.</p> |

| <b>*prompt*</b> |                                                                                                                                 | <i>Variable</i> |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary         | Defines the LispWorks listener prompt.                                                                                          |                 |
| Package         | <code>lispworks</code>                                                                                                          |                 |
| Initial value   | <code>"~%~A ~D~ [~:;~:~* : ~D~] &gt; "</code>                                                                                   |                 |
| Description     | <p>The variable <code>*prompt*</code> defines the LispWorks listener prompt. Its value can be a:</p> <p>Function designator</p> |                 |
|                 | <p>A function of zero arguments which should return the prompt as a string.</p>                                                 |                 |
| String          | <p>A format string with processing three arguments: the current package name, the next history number, and the debug level.</p> |                 |
| A form          | <p>The form is passed to <code>eval</code> and should return a format string, which is used as for the string case above.</p>   |                 |

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description            | <p>The macros <code>push-end</code> and <code>push-end-new</code> are analogs to <code>push</code> and <code>pushnew</code>, except that they append <i>item</i> to the end of the list rather than prepend it.</p> <p><i>place</i> must contain a proper list.</p> <p><code>push-end</code> sets <i>place</i> to a copy of this list with <i>item</i> appended in the end.</p> <p><code>push-end-new</code> does the same as <code>push-end</code>, except when <i>item</i> is already on the list, in which case <code>push-end-new</code> does nothing. The check is done using the values of <i>key</i>, <i>test</i> and <i>test-not</i> in the same way that <code>pushnew</code> does.</p> <p>The return value <i>new-place-value</i> is the value of <i>place</i> after the operation. Except when <i>item</i> is already in the list, it is always a new list.</p> |
| Notes: Multi-threading | <p><code>push-end</code> and <code>push-end-new</code> are not atomic.</p> <p>If <i>place</i> is globally accessible and may be read by another thread without synchronization (by a <code>lock</code> or other synchronization mechanism), then you need to wrap <i>place</i> by <code>globally-accessible</code>, for example:</p> <pre>(push-end my-item           (sys:globally-accessible            *a-global-symbol*))</pre> <p>See “Making an object's contents accessible to other threads” on page 268 for a discussion.</p> <p><code>push</code> and <code>pushnew</code> also have the same issues with Multi-threading.</p>                                                                                                                                                                                                                                   |

| Values      | <code>quit</code> does not return, or returns <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |  |
| Description | <p>The function <code>quit</code> exits LispWorks unless the user cancels the operation.</p> <p>There are two stages which may allow the user the chance to cancel.</p> <ol style="list-style-type: none"> <li>1. First the action items of the action list "<code>Confirm when quitting image</code>" are run. If any action item returns <code>nil</code>, then LispWorks does not exit.</li> <li>2. Otherwise, if <code>confirm</code> is true (the default value is <code>nil</code>) then a question like<br/> <code>"Do you really want to exit LispWorks?"</code> is presented to the user. If the answer No is supplied, then LispWorks does not exit. Otherwise, the action items of the action list "<code>When quitting image</code>" are run, and then LispWorks exits, and the value <code>status</code> is returned to the Operating System as the exit value of the LispWorks process. The default value of <code>status</code> is 0.</li> </ol> <p>If <code>ignore-errors-p</code> is true, then any error signaled during the running of the action list items or the confirm prompt is ignored and <code>quit</code> proceeds to exit the image. If <code>ignore-errors-p</code> is <code>nil</code> and an error is signaled during the running of the action list items, then a restart is available allowing the user to choose to continue to exit the image. The default values of <code>ignore-errors-p</code> is <code>nil</code>.</p> <p>If <code>return</code> is true and LispWorks is going to exit, then <code>quit</code> returns <code>t</code>. This can be used if you want some other Lisp pro-</p> |                        |  |

cess to kill the current one later, rather than it self-destructing immediately. This can be useful to allow more precise control over process termination. If *return* is `nil` then `quit` does not return. The default value of *return* is `nil`.

| Notes    | On Cocoa, when you define your own application menu (by passing <code>:application-menu</code> when making the application interface), the <code>Quit</code> menu item needs to call <code>capi:destroy</code> on the application interface, rather than <code>quit</code> . See <code>capi:cocoa-default-application-interface</code> in the <i>CAPI User Guide and Reference Manual</i> for more information. |

| Arguments   | <table><tr><td>vars</td><td>The variables to be rebound.</td></tr><tr><td>body</td><td>A body of forms, the variables in which should be unique.</td></tr></table>                                                                                                                                   | vars | The variables to be rebound. | body | A body of forms, the variables in which should be unique. |
| vars        | The variables to be rebound.                                                                                                                                                                                                                                                                         |      |                              |      |                                                           |
| body        | A body of forms, the variables in which should be unique.                                                                                                                                                                                                                                            |      |                              |      |                                                           |
| Values      | Returns the body wrapped in a form that creates unique names for each variable.                                                                                                                                                                                                                      |      |                              |      |                                                           |
| Description | Returns the <i>body</i> wrapped in a form which creates a unique name for each of the variables (compare with <code>gensym</code> ) and binds these names to the values of the variables. This ensures that the body can refer to the variables without name clashes with other variables elsewhere. |      |                              |      |                                                           |

Example      After defining

```
(defmacro lister (x y)
  (rebinding (x y)
    '(list ,x ,y)))
```

the form `(lister i j)` macroexpands to

```
(LET* ((#:X-77 I)
       (#:Y-78 J))
      (LIST #:X-77 #:Y-78))
```

## **regexp-find-symbols** *Function*

Summary      Returns a list of symbols that match a supplied regular expression.

Package      **lispworks**

Signature      **regexp-find-symbols** *regexp-string* &key *case-sensitive* *packages*  
*test external-only => symbols*

Arguments      *regexp-string*      A string.

*case-sensitive*      A boolean.

*packages*      A list of package designators, a single package designator, or the keyword :all.

*test*      A function of one argument returning a boolean result.

*external-only*      A generalized boolean.

Values      *symbols*      A list of symbols.

Description      The function **regexp-find-symbols** returns a list of symbols that match the regular expression in *regexp-string*.

*case-sensitive* determines whether the match is case sensitive. The default value of *case-sensitive* is `nil`.

*packages* specifies in which packages to search. The default value of *packages* is `:all`, meaning search in all packages.

*test*, if supplied, must be a function of one argument, which returns `t` if the argument should be returned, and `nil` otherwise. The function *test* is applied to each symbol that matches *regexp-string*, and if it returns `nil` the symbol is not included in the returned value *symbols*. If *test* is `nil` all matches are returned. The default value of *test* is `nil`.

*external-only*, if true, specifies that only external symbols should be checked, which makes the search much faster. The default value of *external-only* is `nil`.

The regular expression syntax used by `regexp-find-symbols` is similar to that used by Emacs, as described in the "Regular expression syntax" section of the *LispWorks Editor User Guide*.

Examples To find all exported symbols that start with DEF:

```
(lw:regexp-find-symbols "^def" :external-only t)
```

To find all symbols that contain lower case "slider":

```
(regexp-find-symbols "slider" :case-sensitive t)
```

| Signature   | <code>remove-advice function-dspec name =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments   | <p><code>function-dspec</code> A function-dspec Specifies the function definition to which the piece of advice belongs. See “Function dspecs” on page 84 for description of function-dspec.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <p><code>name</code> A symbol naming the piece of advice to be removed. Since several pieces of advice may be attached to a single functional definition, the name is necessary to indicate which one is to be removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | <code>remove-advice</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p><code>remove-advice</code> is the function used to remove a piece of advice. Advice is a way of altering the behavior of functions. Pieces of advice are associated with a function using <code>defadvice</code>. They define additional actions to be performed when the function is invoked, or alternative code to be performed instead of the function, which may or may not access the original definition. As well as being attached to ordinary functions, advice may be attached to methods and to macros (in this case it is in fact associated with the macro’s expansion function).</p> <p><code>hcl:delete-advice</code> is a macro, identical in effect to <code>remove-advice</code>, except that you do not need to quote the arguments.</p> |
| Notes       | <code>remove-advice</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <i>integer</i>     | An integer.                                                                                                                                                                                                                                                   |              |             |                 |                   |                |             |
| Values             | <i>result-integer</i> An integer.                                                                                                                                                                                                                             |              |             |                 |                   |                |             |
| Description        | The function <code>rotate-byte</code> returns <i>integer</i> with the bits specified by <i>bytespec</i> rotated left by <i>count</i> bits. Other bits remain the same as in <i>integer</i> . If <i>count</i> is negative, then the effect is to rotate right. |              |             |                 |                   |                |             |

| Values              | <i>double-float</i>                                                                                                                                                                                                                                  | A <b>double-float</b> with <b>single-float</b> precision.                                                                                                                                                                                                                                                                                                               |
| Description         | The argument is rounded to single-precision format (32 bits) and returned as a <b>double-float</b> (64 bits). This function allows you to model the rounding behavior of a machine or implementation that performs 32-bit floating point arithmetic. | LispWorks supports multiple floating point formats: <b>short-float</b> (only on 32-bit LispWorks), <b>single-float</b> and <b>double-float</b> . If this function is called with a <b>single-float</b> or a <b>short-float</b> , it returns the equivalent <b>double-float</b> , that is, it is the same as evaluating<br><br><code>(coerce float 'double-float)</code> |
| Compatibility notes | LispWorks 4.4 and previous on Windows and Linux platforms supports just one floating point format. In LispWorks 5.0 and later, at least two floating point formats are supported on all platforms.                                                   |                                                                                                                                                                                                                                                                                                                                                                         |
| Example             | <br><code>CL-USER 197 &gt; pi</code><br><code>3.141592653589793D0</code><br><br><code>CL-USER 198 &gt; round-to-single-precision pi</code><br><code>3.1415927410125732D0</code>                                                                      |                                                                                                                                                                                                                                                                                                                                                                         |

|           |                                              | <i>Function</i>               |
|-----------|----------------------------------------------|-------------------------------|
| Summary   | The accessor for simple base strings.        |                               |
| Package   | <code>lispworks</code>                       |                               |
| Signature | <code>sbchar string index =&gt; value</code> |                               |
| Arguments | <i>string</i>                                | A <b>simple-base-string</b> . |
|           | <i>index</i>                                 | An index.                     |

|             |                                                                       |                                                  |
|-------------|-----------------------------------------------------------------------|--------------------------------------------------|
| Values      | <i>value</i>                                                          | The character in <i>string</i> at <i>index</i> . |
| Description | This is the accessor for simple base strings. <b>setf</b> is allowed. |                                                  |
| See also    | <b>simple-base-string</b>                                             |                                                  |

## **sequencep** *Function*

|             |                                                                                                             |                        |
|-------------|-------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | A predicate to check for sequences.                                                                         |                        |
| Package     | <b>lispworks</b>                                                                                            |                        |
| Signature   | <b>sequencep</b> <i>object</i> => <i>result</i>                                                             |                        |
| Arguments   | <i>object</i>                                                                                               | A Lisp object.         |
| Values      | <i>result</i>                                                                                               | A generalized boolean. |
| Description | The function <b>sequencep</b> returns true if <i>object</i> is of type <b>sequence</b> and false otherwise. |                        |
| Examples    | <pre>(sequencep '(1 2 3)) =&gt; t (sequencep #(1 2 3)) =&gt; t (sequencep 123) =&gt; nil</pre>              |                        |

## **set-default-character-element-type** *Function*

|           |                                                                               |  |
|-----------|-------------------------------------------------------------------------------|--|
| Summary   | Configures the value of <b>lw:*default-character-element-type*</b> .          |  |
| Package   | <b>lispworks</b>                                                              |  |
| Signature | <b>set-default-character-element-type</b> <i>type</i> => <i>type-defaults</i> |  |

|                     |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments           | <code>type</code>          | A character type. This can take any of the values <code>cl:base-char</code> , <code>bmp-char</code> and <code>cl:character</code> . For backwards compatibility, <code>simple-char</code> is also allowed, and is treated as if <code>cl:character</code> was passed.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Values              | <code>type-defaults</code> | The new value of <code>lw:*default-character-element-type*</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description         |                            | <p>The function <code>set-default-character-element-type</code> sets the value of <code>lw:*default-character-element-type*</code>, ensuring that the system's internal state is also updated accordingly.</p> <p>If you are running an existing 8-bit application you will only need to have this in your site or user configuration file:</p> <pre>(lw:set-default-character-element-type 'base-char)</pre> <p>It would be a mistake to call this function in a loadable package and it is not intended to be called while running code. In particular, it is global, not thread-specific.</p> <p>Hence we consider <code>lw:*default-character-element-type*</code> a parameter.</p> |
| Compatibility note: |                            | <code>simple-char</code> is deprecated. Its meaning has changed between LispWorks 6 and 7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Arguments   | <code>on</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <code>nil</code> , <code>t</code> or the keyword <code>:check</code> |
| Description | <p>The function <code>set-quit-when-no-windows</code> can be used at run time in a delivered application to override the value of the <code>:quit-when-no-windows</code> keyword to <code>deliver</code>. This can be useful if the application runs in various modes, some with windows and some without. It has no effect in a non-delivered application.</p> <p>If <code>on</code> is <code>nil</code>, then the application will not quit merely because there are no remaining open windows.</p> <p>If <code>on</code> is <code>t</code>, then the application will quit when there are no remaining open windows after the application has opened at least one CAPI window.</p> <p>If <code>on</code> is <code>:check</code>, then the application will quit immediately if there are no open windows at the current time. Unlike with <code>:quit-when-no-windows t</code>, this occurs even if the application has not opened any CAPI windows so far. If there are open windows currently, then it turns on quitting like when <code>on</code> is <code>t</code>.</p> |                                                                      |
| See also    | <p><code>:quit-when-no-windows</code> in the <i>LispWorks Delivery User Guide</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                      |

|         |                                                                    | <i>Type</i> |
|---------|--------------------------------------------------------------------|-------------|
| Summary | The simple character type. <code>simple-char</code> is deprecated. |             |
| Package | <code>lispworks</code>                                             |             |

|             |                                                                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>simple-char</code>                                                                                                                                                                                                     |
| Description | <p>The type of simple characters (standard term for chars with null implementation-defined attributes, that is, no bits).</p> <p><code>simple-char</code> is a synonym for <code>cl:character</code>, and is deprecated.</p> |
| Notes       | 16-bit characters and 16-bit strings are implemented by the types <code>bmp-char</code> and <code>bmp-string</code> and <code>simple-bmp-string</code> .                                                                     |

## **simple-char-p** *Function*

| Description | <p>The function <b>split-sequence</b> returns a list of subsequences of <i>sequence</i> (between <i>start</i> and <i>end</i>), split when an element in the sequence <i>separator-bag</i> is found. The structure of <i>sequence</i> is not changed and the elements matching <i>separator-bag</i> are not included in the resulting sequences.</p> <p>The function <i>test</i>, which defaults to <code>eq1</code>, is used to compare the elements of <i>sequence</i> and the elements of <i>separator-bag</i>.</p> <p>If true, the function <i>key</i>, is applied to the elements of <i>sequence</i> before <i>test</i> is called.</p> <p>If <i>coalesce-separators</i> is true, then empty sequences are removed.</p> |                                                  |

| Description | <p>The function <code>split-sequence-if</code> returns a list of subsequences of <i>sequence</i> (between <i>start</i> and <i>end</i>), split by where the function <i>predicate</i> returns true for an element. The structure of <i>sequence</i> is not changed and the elements identified by the predicate are not included in the resulting sequences.</p> <p>If non-nil, the function <i>key</i> is applied to the elements of <i>sequence</i> before <i>predicate</i> is called.</p> <p>If <i>coalesce-separators</i> is true, then empty sequences are omitted from <i>result</i>.</p> |                                                  |

| Description | <p>The function <code>start-tty-listener</code> returns a process that runs a listener read-eval-print loop connected to <code>*terminal-io*</code>. If <i>force</i> is <code>nil</code>, then <code>start-tty-listener</code> checks whether the default listener process is alive or if there is a live process with name "TTY Listener". If such a process exists, <code>start-tty-listener</code> simply returns <code>nil</code> and does not start a new process. If no such process exists, or if <i>force</i> was <code>t</code>, then <code>start-tty-listener</code> starts a new listener process named "TTY Listener", and returns it.</p> <p>If a REPL with I/O through <code>*terminal-io*</code> (such as a REPL started by <code>start-tty-listener</code>) is in the debugger, then by default it blocks multiprocessing. This behavior is controlled by the value of <code>*terminal-debugger-block-multiprocessing*</code>.</p> |                                           |

| Arguments     | <i>string</i>                                | A <code>simple-text-string</code> .              |
|               | <i>index</i>                                 | An index.                                        |
| Values        | <i>value</i>                                 | The character in <i>string</i> at <i>index</i> . |

Description This is the accessor for simple text strings. `setf` is allowed.

## **string-append** *Function*

Summary Constructs a single string from a number of strings.

Package `lispworks`

Signature `string-append &rest strings => string`

Arguments `strings` Any number of string designators.

Values `string` A string.

Description The function `string-append` takes any number of string designators and constructs a single string from them.

Each of the elements of the `strings` argument is first coerced into a string using the `string` function if it is not already a string.

`string` is a string of the "widest" type amongst `strings`. That is, the constructed string is of the same type as the argument with the largest element type.

Example      `(readtable-case *readtable*)`

`=>`  
`:UPCASE`

`(string-append "foo" 'bar)`  
`=>`  
`"fooBAR"`

`(type-of`  
  `(string-append`  
    `(coerce "A" 'simple-base-string)`  
    `(coerce "A" 'simple-text-string)`  
  `))`  
`=>`  
`SIMPLE-TEXT-STRING`

## **string-append\***

*Function*

Summary     Constructs a single string from a list of strings.

Package     `lispworks`

Signature    `string-append* strings => string`

Arguments    `strings`       A list of string designators.

Values       `string`       A string.

Description    The function `string-append*` takes a list of string designators and constructs a single string from them.

Each of the elements of the `strings` argument is first coerced into a string using the function `string` if it is not already a string.

`string` is a string of the "widest" type amongst `strings`. That is, the constructed string is of the same type as the string with

the largest element type amongst those supplied in the argument.

|          |                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example  | <pre>(readtable-case *readtable*) =&gt; :UPCASE  (string-append* '("foo" bar)) =&gt; "fooBAR"  (type-of   (string-append*     (list (coerce "A" 'simple-base-string)           (coerce "A" 'simple-text-string)         ))) =&gt; SIMPLE-TEXT-STRING</pre> |
| See also | <code>string-append</code>                                                                                                                                                                                                                                 |

## **structurep** *Function*

|             |                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| Summary     | A predicate to check for structure objects.                                                                                      |
| Package     | <code>lispworks</code>                                                                                                           |
| Signature   | <code>structurep object =&gt; result</code>                                                                                      |
| Arguments   | <code>object</code> A Lisp object.                                                                                               |
| Values      | <code>result</code> A generalized boolean.                                                                                       |
| Description | The function <code>structurep</code> returns true if <i>object</i> is of type <code>structure-object</code> and false otherwise. |
| Examples    | <code>(structurep #(1 2 3)) =&gt; nil</code><br>Given the definition:<br>                                                        |

```
(defstruct my-struct a)
```

then

```
(structurep (make-my-struct)) => t
```

but metaclasses are not structures so:

```
(structurep (find-class 'my-struct)) => nil
```

## **text-string**

### **simple-text-string**

*Types*

Summary      The text string types.

Package      **lispworks**

Signature      **text-string length**

**simple-text-string length**

Arguments      *length*      The length of the string (or \*, meaning any).

Description      **text-string** is the type of strings that can hold any character, that is, `(vector cl:character length)`. This is the string type that is guaranteed to always hold any character used in writing text (program text or natural language).

**simple-text-string** is the simple version of **text-string**, that is, the string itself is simple. Equivalent to:

```
(simple-vector cl:character length)
```

Notes      **text-string** uses 32 bits per character. Applications that use many strings and are very large, when they know they do not use the full Unicode range, can consider using **base-string** (up to 8 bits) or **bmp-string** (up to 16 bits) to reduce memory usage.

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Compatibility note | In LispWorks 6.1 and earlier versions, <code>text-string</code> uses 16 bits per character.                                   |
| See also           | <code>bmp-string</code><br><code>base-string</code><br><code>text-string-p</code><br>“Character and String types” on page 436 |

| Summary     | Removes an action from a specified list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signature   | <code>undefine-action name-or-list action-name =&gt;</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Arguments   | <code>name-or-list</code> A list or action list object.<br><code>action-name</code> A general lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The macro <code>undefine-action</code> removes the action specified by <code>action-name</code> from the action list specified by <code>name-or-list</code>. If the action specified by <code>action-name</code> does not exist, then this is handled according to the value of <code>*handle-missing-action-in-action-list*</code>.</p> <p><code>name-or-list</code> is evaluated to give either a list UID (to be looked up in the global registry of lists) or an action list object. <code>action-name</code> is a UID (general lisp object, to be compared by <code>equalp</code>). It uniquely identifies this action within its list (as opposed to among all lists).</p> |

## **undefine-action-list** *Macro*

Summary      Removes a given defined action list.

Package      **lispworks**

Signature      **undefine-action-list *uid* =>**

Arguments      ***uid***                  A lisp object.

Values      None.

Description      The macro **undefine-action-list** flushes the specified list (and all its action-items). If the action-list specified by ***uid*** does not exist, then handling is controlled by the value of the variable **\*handle-missing-action-list\***.

See also      **define-action-list**

## **unicode-alpha-char-p** *Function*

Summary      Returns a value like **c1:alpha-char-p**, but using specified Unicode rules.

Package      **lispworks**

Signature      **unicode-alpha-char-p *char* &key *style* => *flag***

Arguments      ***char***                  A character

***style***                  A keyword

Values      ***flag***                  A generalized boolean

|             |                                                                                                                                                                                                                                                                                  |

**unicode-both-case-p**

## **unicode-both-case-p** *Function*

Summary      Returns a value like `c1:both-case-p`, but using specified Unicode rules.

Package      **lispworks**

Signature      **unicode-both-case-p** *char* &**key** *style* => *flag*

Arguments      *char*      A character

*style*      A keyword

Values      *flag*      A generalized boolean

Description      The function `unicode-both-case-p` returns *flag* as true if *char* has case according to the Unicode rules specified by *style*.

The current implementation only supports one style:

**:general-category**

Use the "general category" for *char* in Unicode 6.3.0.

Notes      The name of `unicode-both-case-p` is slightly confusing, because it matches the ANSI Common Lisp definition "a character with case" whereas there is no guarantee that both cases actually exist. Note also that there are some "alpha" chars which are not lower or upper case.

**unicode-upper-case-p**

## **unicode-char-equal**

## **unicode-char-not-equal**

## *Functions*

Summary      Compares two characters, ignoring case using specified Unicode rules.

Package      **lispworks**

Signatures    **unicode-char-equal *char1* *char2* &key *style* => *flag***  
**unicode-char-not-equal *char1* *char2* &key *style* => *flag***

Arguments    *char1*      A character

*char2*      A character

*style*      A keyword

Values        *flag*      A generalized boolean

Description    The function **unicode-char-equal** returns true if the characters *char1* and *char2* are equal, and the function **unicode-char-not-equal** returns true if the characters *char1* and *char2* are not equal. Both functions ignore case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

                Compares characters using the simple case folding rules in Unicode 6.3.0.

See also     **unicode-char-greaterp**

**unicode-char-greaterp****unicode-char-lessp***Functions*

**Summary**      Compares two characters, ignoring case using specified Unicode rules.

**Package**      **lispworks**

**Signatures**      **unicode-char-greaterp *char1* *char2* &key *style* => *flag***  
**unicode-char-lessp *char1* *char2* &key *style* => *flag***

**Arguments**      ***char1***      A character

***char2***      A character

***style***      A keyword

**Values**      ***flag***      A generalized boolean

**Description**      The functions **unicode-char-greaterp** and **unicode-char-lessp** return true if the character *char1* is greater than (or for **unicode-char-lessp**, less than) the character *char2*, similarly to **cl:char-greaterp** and **cl:char-lessp** but ignoring case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

                  Compares characters using the simple lowercase folding rules in Unicode 6.3.0.

**See also**      **unicode-char-equal**

**unicode-char-not-greaterp**

*Function*

**unicode-char-not-greaterp**

**unicode-char-not-lessp**

*Functions*

Summary      Compares two characters, ignoring case using specified Unicode rules.

Package      **lispworks**

Signatures    **unicode-char-not-greaterp *char1 char2 &key style => flag***  
**unicode-char-not-lessp *char1 char2 &key style => flag***

Arguments     *char1*      A character

*char2*      A character

*style*      A keyword

Values        *flag*      A generalized boolean

Description     The functions **unicode-char-not-greaterp** and **unicode-char-not-lessp** return true if the character *char1* is not greater (or for **unicode-char-not-lessp**, not less) than the character *char2*, similarly to **c1:char-not-greaterp** and **c1:char-not-lessp** but ignoring case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares characters using the simple lowercase folding rules in Unicode 6.3.0.

## **unicode-string-greaterp**

## **unicode-string-lessp**

### *Functions*

**Summary**      Compares two strings, ignoring case using specified Unicode rules.

**Package**      **lispworks**

**Signatures**      **unicode-string-greaterp** *string1 string2 &key start1 start2 end1 end2 style => mismatch-index*

**unicode-string-lessp** *string1 string2 &key start1 start2 end1 end2 style => mismatch-index*

**Arguments**

|                     |                                              |
|---------------------|----------------------------------------------|
| <i>string1</i>      | A string designator                          |
| <i>string2</i>      | A string designator                          |
| <i>start1, end1</i> | Bounding index designators of <i>string1</i> |
| <i>start2, end2</i> | Bounding index designators of <i>string2</i> |
| <i>style</i>        | A keyword                                    |

**Values**      *mismatch-index* A bounding index of *string1* or **nil**

**Description**      The functions **unicode-string-greaterp** and **unicode-string-lessp** compare the designated substrings of *string1* and *string2*, similarly to **c1:string-greaterp** and **c1:string-greaterp** but ignoring case using Unicode rules specified by *style*. The values of *start1* and *start2* default to 0, while the values of *end1* and *end2* default to **nil**.

The value of *mismatch-index* is the index where the strings mismatch (as an offset from the beginning of *string1*) if *substring1* is greater (or for **unicode-string-lessp**, less) than *substring2*, or **nil** otherwise.

The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares each character of the string using the simple lowercase folding rules in Unicode 6.3.0.

| Values      | <code><i>mismatch-index</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A bounding index of <code><i>string1</i></code> or <code>nil</code> |
| Description | The functions <code>unicode-string-not-greaterp</code> and <code>unicode-string-not-lessp</code> compare the designated substrings of <code><i>string1</i></code> and <code><i>string2</i></code> , similarly to <code>cl:string-not-greaterp</code> and <code>cl:string-not-lessp</code> but ignoring case using Unicode rules specified by <code><i>style</i></code> . The values of <code><i>start1</i></code> and <code><i>start2</i></code> default to 0, while the values of <code><i>end1</i></code> and <code><i>end2</i></code> default to <code>nil</code> . |                                                                     |

The value of *mismatch-index* is the index where the strings mismatch (as an offset from the beginning of *string1*) if *substring1* is not greater (or for `unicode-string-not-lessp`, not less) than *substring2*, or `nil` otherwise.

The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares each character of the string using the simple lowercase folding rules in Unicode 6.3.0.

                  `unicode-string-greaterp`

## **unicode-upper-case-p** *Function*

Summary      Returns a value like `c1:upper-case-p`, but using specified Unicode rules.

Package      `lispworks`

Signature      `unicode-upper-case-p char &key style => flag`

Arguments      `char`      A character  
                  `style`      A keyword

Values      `flag`      A generalized boolean

Description      The function `unicode-upper-case-p` returns *flag* as true if *char* is uppercase according to the Unicode rules specified by *style*.

The current implementation only supports one style:

**:general-category**

Use the "general category" for *char* in Unicode 6.3.0.

| Values      | <i>value</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A Lisp object.                 |
|             | <i>valuep</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A boolean.                     |
| Description | <p>The function <b>user-preference</b> reads the value of the registry entry <i>value-name</i> under <i>path</i> under the registry path defined for <i>product</i> by <b>(setf product-registry-path)</b>. If the registry entry was found a second value <i>t</i> is returned. If the registry entry was not found, then <i>value</i> is <b>nil</b>.</p> <p>The function <b>(setf user-preference)</b> sets the value of that registry entry to <i>value</i>.</p> <p>If <i>path</i> is a list of strings, then it is interpreted like the directory component of a pathname. If <i>path</i> is a string, then any directory separators should be appropriate for the platform -</p> |                                |

that is, use backslash on Windows, and forward slash on non-Windows systems.

Notes

1. When *value* is a string, `user-preference` stores a print-escaped string in the registry and reads it back with `read-from-string`. Therefore it may not work with string values stored by other software.
2. While *product* can in principle be any Lisp object, values of *product* are compared by `eq`, so you should use keywords.
3. The CAPI provides a way to store window geometry - see the reference entry for `capi:top-level-interface-save-geometry-p` in the *CAPI User Guide and Reference Manual*.

Example

This example is on Microsoft Windows. Note the use of backslashes as directory separators in the *path* argument:

```
(setf (user-preference "My Stuff\\FAQ"
                      "Ultimate Answer"
                      :product :deep-thought)
      42)
=>
42
```

This is equivalent to the previous example, and is portable because we avoid the explicit directory separators in the *path* argument:

```
(setf (user-preference (list "My Stuff" "FAQ")
                      "Ultimate Answer"
                      :product :deep-thought)
      42)
=>
42
```

We can retrieve values on Windows like this:

```
(user-preference "My Stuff\\FAQ"
                 "Ultimate Answer"
                 :product :deep-thought)
=>
42
t
```

We can retrieve values on any platform like this:

```
(user-preference (list "My Stuff" "FAQ")
                 "Ultimate Question"
                 :product :deep-thought)
=>
nil
nil
```

| Values           | <i>result</i>                                                                                                                                                                                                                                                                                                                  | The result of evaluating <i>body</i> using the value <i>var</i> . |                                                                   |             |                                         |             |                                                                             |  |

|             |                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <code>when-let*</code> expands into nested <code>when-let</code> forms. The bindings are evaluated in turn as long as each returns non-nil. If the last binding evaluates to non-nil, <code>body</code> is executed. Within the code <code>body</code> , each variable <code>var</code> is bound to the result of the corresponding form <code>form</code> . |
| Example     | <pre>(defmacro divisible (n &amp;rest divisors)   `(~(when-let* , (loop for div in divisors                          collect (list (gensym)                                        (zerop (mod n div))))))     t))</pre>                                                                                                                                               |
| See also    | <code>when-let</code>                                                                                                                                                                                                                                                                                                                                                  |

| Description                     | The macro <code>with-action-item-error-handling</code> executes the <i>body</i> with <i>action-list-var</i> and <i>action-item-var</i> are bound to the action list and item respectively. If <i>ignore-errors-p</i> is set to <code>t</code> then errors are handled. The behavior of the handler is to signal a warning in which the action-list, item and original error are all reported; execution then continues with the next action-item.                                                                                                                                                                                                                                                                                                                             |
| Example                         | <pre>(defun my-execution-function (the-action-list                                other-args                                &amp;key ignore-errors-p                                &amp;allow-other-keys)   (with-action-list-mapping (the-action-list                             an-action-item                             action-item-data)     (with-action-item-error-handling (the-action-list                                       an-action-item                                       ignore-errors-p)       (do-something-interesting-first)       (apply (car action-item-data) other-args (cdr action-item-data)))))</pre> <p>If this function was invoked with the keyword argument <code>:ignore-errors-p t</code>, and an error was signaled while exe-</p> |

cuting the body-form(s) for one of the action-items, then a warning such as:

```
Warning: Got an error 'The variable *PREV-STATE* is  
unbound.' while executing action "Initialize State" in  
list "Startup Inits".
```

would be signaled and execution would continue with the next action-item.

## **with-action-list-mapping** *Macro*

**Summary** Maps over an action list's actions with given variables bound to the executing action and its data.

**Package** `lispworks`

**Signature** `with-action-list-mapping action-list item-var data-var  
&optional post-process &body body`

**Arguments** `action-list` An action list.

`item-var` A Lisp symbol.

`data-var` A Lisp symbol.

`post-process` A keyword.

`body` A body of Lisp code.

**Description** The macro `with-action-list-mapping` maps over an action-list's action-items. During execution, the symbols specified for `item-var` and `data-var` are bound to the executing action-item and its data respectively. See `execute-actions` for more on post-processing.

If this function is invoked with the keyword argument `:post-process :collect`, a list the values returned by each action-item's setf operation are returned.

**Examples**

```
(defun my-execution-function
  (the-action-list other-args
    &key (post-process nil)
    &allow-other-keys)
  (declare (ignore other-args))
  (with-action-list-mapping (the-action-list
    an-action-item
    action-item-data
    post-process)
    (do-something-interesting-first)

      (apply (cadr action-item-data)
        (cddr action-item-data)))))
```

**See also****execute-actions****with-unique-names***Macro*

**Summary** Returns a body of code with each specified name bound to a similar name.

**Package** **lispworks**

**Signature** **with-unique-names (&rest names) &body body => result**

**Arguments** **names** The names to be rebound in *body*.

**body** The body of code within which *names* are rebound.

**Values** **result** The result of evaluating *body*.

**Description** Returns the body with each *name* bound to a symbol of a similar name (compare **gensym**).

**Example** After defining

```
(defmacro lister (p q)
  (with-unique-names (x y)
    `(let ((,x (x-function))
          (,y (y-function)))
      (list ,p ,q ,x ,y))))
```

the form (**lister i j**) macroexpands to

```
(LET* ((#:X-88 (X-FUNCTION))
       (#:Y-89 (Y-FUNCTION)))
  (LIST i j #:X-88 #:Y-89))
```

## The LW-JI Package

This chapter describes symbols available in the `LW-JI` package, the LispWorks Java interface.

The uses of these symbols are discussed in Chapter 15, “Java interface”.

|             |                                                                                                                                                                                                                                 | <i>Function</i> |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary     | Call a Java method.                                                                                                                                                                                                             |                 |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                              |                 |
| Signature   | <code>call-java-method <i>method-name</i> &amp;rest <i>args</i></code>                                                                                                                                                          |                 |
| Arguments   | <i>method-name</i>                                                                                                                                                                                                              | A string.       |
|             | <i>args</i>                                                                                                                                                                                                                     | Lisp objects.   |
| Description | The function <code>call-java-method</code> calls a Java method on the supplied <i>args</i> .<br><br><i>method-name</i> must specify the full name of the Java method to call, including the package, class and method name, for |                 |

`example "java.io.File.exists".call-java-method` first uses the string to lookup a caller, and if that fails it produces a caller in the same way that `define-java-caller` and `setup-java-caller` do and caches it. It then uses the caller to call the Java method with `args`, and return the result.

The process of actual calling is the same as in ordinary Java callers defined by `define-java-caller`. See the entry for `define-java-caller` for details.

If *method-name* is incorrect (does not have class and method name, class cannot be found or method cannot be found), `call-java-method` signals an error of type `call-java-method-error`, which reports the actual failure.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>call-java-method</code> needs to lookup the caller using the string, so the call is slightly slower than calls for ordinary Java callers, but the difference is not significant. There is also no way to verify that the string is correct. It also has to keep some extra code that can be shaken out if only <code>define-java-caller</code> is used, but not much. If you find it convenient, there is no reason not to use it. |

|              | <i>Condition</i>                                         |
|--------------|----------------------------------------------------------|
| Summary      | <code>call-java-method</code> failed to find the method. |
| Package      | <code>lw-ji</code>                                       |
| Superclasses | <code>java-interface-error</code>                        |
| Subclasses   | None.                                                    |

Description      The condition class `call-java-method-error` is signaled when `call-java-method` failed to find the method.

See also      `call-java-method`

## **catching-java-exceptions**

### **catching-exceptions-bind**

*Macros*

Summary      Execute Lisp code with a catch for Java exceptions.

Package      `lw-ji`

Signature      `catching-java-exceptions &body body`

Signature      `catching-exceptions-bind (result exception) form &body body`

Arguments      `result`      A variable.

`exception`      A variable.

`form`      A Lisp form.

`body`      Lisp code.

Description      The macro `catching-java-exceptions` executes `body` with a catch for Java exceptions. The code of `body` is executed normally, and if no Java exception is signaled through the execution, returns whatever `body` returns. If there is an exception, instead of signaling an error of class `java-exception`, `catching-java-exceptions` returns two values: `nil` and the Java exception object (analogous to `cl:ignore-errors`).

The macro `catching-exceptions-bind` executes the `form` and binds `result` and `exception` to the first two return values if there was no exception. If there was an exception they are bound to `nil` and the exception. It then executes the code of `body` within the scope of the bind. `catching-exceptions-bind` is equivalent to

```
(multiple-value-bind (result exception)
  (catching-java-exceptions form)
    body)
```

- Notes
1. `jobject-string`, `jobject-class-name` and `jobject-of-class-p` are useful general utilities for deciding what to do with the exception. For find-grained handling, you will need to access the exception using your own callers or `call-java-method` when applicable.
  2. These macros have no effect on signaling and handling of other errors in Lisp, except that they prevent Java exceptions from being signaled as errors.
  3. Some exceptions can happen during normal execution and handled by the system in a user-invisible way (analogous to the way that `try` in Java code does). These macros do not affect the behavior for these cases, so even though when running under a Java debugger you may see an exception, it will not necessarily be visible with these macros.
  4. In general, these macros are less useful in high-level code, because they cause exceptions to throw out, preventing them from being signaled as Lisp errors and handled by error handler in the scope of `body` (for `catching-java-exceptions`) or `form` (for `catching-exceptions-bind`). They should normally be used in low-level code that actually does Java calls, with any Lisp error handlers wrapped around them.
  5. For simple handling of exceptions you can use standard handlers (`c1:handler-case`, `c1:handler-bind`), for `java-exception` and its subclasses.

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Tests whether calls from Java into Lisp can work.                                                                                                                                    |                                                                                                                                                                                                                                                                                |
| Package     | <code>lw-ji</code>                                                                                                                                                                   |                                                                                                                                                                                                                                                                                |
| Signature   | <code>check-lisp-calls-initialized =&gt; result</code>                                                                                                                               |                                                                                                                                                                                                                                                                                |
| Arguments   | None.                                                                                                                                                                                |                                                                                                                                                                                                                                                                                |
| Values      | <i>result</i>                                                                                                                                                                        | A boolean.                                                                                                                                                                                                                                                                     |
| Description | The function <code>check-lisp-calls-initialized</code> returns <code>t</code> if Lisp calls have been initialized successfully, which means that calls from Java into Lisp can work. | The main factor that may affect successful initialization of Lisp calls is the availability of the class <code>com.lisp-works.LispCalls</code> , which comes from LispWorks and will not be available if you do not make it available to the Java Virtual Machine in some way. |
| Notes       | On Android the <code>LispCalls</code> class is available because it is in the <code>lispworks.jar</code> file that must be included in the application.                              |                                                                                                                                                                                                                                                                                |
| See also    | “Calling from Java to Lisp” on page 206                                                                                                                                              |                                                                                                                                                                                                                                                                                |

| Arguments   | <i>jobject</i>  | A <i>jobject</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | <i>errorp</i>   | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <i>instance</i> | A CLOS object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |                 | <p>The function <code>create-instance-from-jobject</code> creates a CLOS instance based on the <i>jobject</i> <i>jobject</i>.</p> <p><i>jobject</i> must be a <i>jobject</i>. Its class name (that is, the result of <code>jobject-class-name</code>) must have been associated with the name of a CLOS subclass of <code>standard-java-object</code> using <code>record-java-class-lisp-symbol</code> (the importing interface, when defining a class, does it automatically).</p> <p><code>create-instance-from-jobject</code> uses the record to find the class, and makes the CLOS instance by calling <code>make-instance</code>, passing it <i>jobject</i>.</p> <p>The result is an instance of the CLOS class, which can be passed to Java interface functions and Java methods.</p> <p>If <code>create-instance-from-jobject</code> fails to find the CLOS class it signals an error if <i>errorp</i> is non-nil, otherwise it returns <code>nil</code>. The default value of <i>errorp</i> is true.</p> |

| Arguments   | <i>instance</i> | An instance of a subclass of <b>standard-java-object</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>args</i>     | A list or t.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values      | <i>jobject</i>  | A jobject.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description |                 | <p>The functions <code>create-instance-jobject-list</code> and <code>create-instance-jobject</code> construct a jobject for the CLOS instance <i>instance</i> and set its slot to that <i>jobject</i>.</p> <p>The type of <i>instance</i> (that is, the class name of its class) must have been associated with a Java constructor by passing it as the <i>class-symbol</i> argument to <code>define-java-constructor</code> or <code>setup-java-constructor</code></p> <p><code>create-instance-jobject</code> just calls <code>create-instance-jobject-list</code> with <i>instance</i> and <i>args</i>.</p> <p><code>create-instance-jobject-list</code> constructs the <i>jobject</i> using the <i>args</i>. <i>args</i> can be either the list of arguments for the constructor (the list may be <code>nil</code>), or t, in which case <code>create-instance-jobject-list</code> uses <code>default-constructor-arguments</code> to create a list of arguments and uses it instead. The Java constructor is called in the same way that it would be called by the caller that is defined by <code>define-java-constructor</code>. See <code>define-java-constructor</code> for details of calling. The result of the construction is stored in <i>instance</i> and is returned.</p> |
| Notes       |                 | <ol style="list-style-type: none"> <li>1. The importing interface, when defining a class, automatically generates the <code>define-java-constructor</code> form passing it the <i>class-symbol</i> argument. <code>define-java-constructor</code> also defines a caller for the constructor, which can be used independently. <code>create-instance-jobject-list</code> and <code>create-instance-jobject</code> do not actually call it, but share information with it.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

2. `create-instance-jobject-list` and `create-instance-jobject` ignore the current `jobject` in `instance`, if there is one. There is no problem calling `create-instance-jobject-list` and `create-instance-jobject` repeatedly on the same instance.

## `create-java-object` *Function*

Summary      Invoke the Java constructor.

Package      `lw-ji`

Signature      `create-java-object class-name &rest args => result`

Arguments      `class-name`      A string.

`args`      Lisp objects.

Values      `result`      A Java object.

Description      The function `create-java-object` invokes the Java constructor for the class `class-name` with the supplied `args`.

`class-name` must specify a Java class. `create-java-object` first uses `class-name` to lookup a caller, and if that fails it produces a caller in the same way that `define-java-constructor` and `setup-java-constructor` do and caches it. It then uses the caller to call the constructor with `args`, and returns the result.

The process of actual calling is the same as in ordinary Java callers defined by `define-java-constructor`. See the entry for `define-java-constructor` for details.

If the string is incorrect (that is, it does not look like a Java class name or the class cannot be found), `create-java-`

`object` signals an error of type `create-java-object-error`, which reports the actual failure.

|          |                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>create-java-object</code> needs to lookup the caller using the string, so the call is slightly slower than calls for ordinary Java constructors, but the different is not significant. It also has to keep some extra code that can be shaken out if only <code>define-java-constructor</code> is used, but not much. If you find it convenient, there is no reason not to use it. |

| Method signatures | <code>default-constructor-arguments (instance standard-java-object) =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Arguments         | <i>instance</i> An instance of a subclass of <code>standard-java-object</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values            | <i>list</i> A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description       | <p>The generic function <code>default-constructor-arguments</code> returns a default list of arguments to pass to the constructor.</p> <p>It is used by <code>create-instance-jobject-list</code> when its <code>args</code> argument is <code>t</code>. <code>default-constructor-arguments</code> is also used by the <code>c1:initialize-instance</code> method of <code>standard-java-object</code> when <code>:construct</code> is passed with value <code>t</code>. It is intended for you to specialize on your own classes.</p> <p>The default method returns <code>nil</code>, which is sometimes useful, but in most cases you probably need to pass something.</p> |
| See also          | <code>create-instance-jobject-list</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|           | <i>Function</i>                                                                     |
|-----------|-------------------------------------------------------------------------------------|
| Summary   | The default <i>name-constructor</i> used by the importing interface.                |
| Package   | <code>lw-ji</code>                                                                  |
| Signature | <code>default-name-constructor prefix method-or-field-name =&gt; symbol-name</code> |
| Arguments | <i>prefix</i> A string.<br><i>method-or-field-name</i><br>A string.                 |
| Values    | <i>symbol-name</i> A string.                                                        |

|             |                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>default-name-constructor</code> is the default <i>name-constructor</i> used by the importing interface. See <code>generate-java-class-definitions</code> for a description of what it does. |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## define-field-accessor *Macro*

Summary      Defines a Java field accessor.

Package      `lw-ji`

Signature      `define-field-accessor name class-name field-name static-p &optional is-final => name`

|           |                   |            |
|-----------|-------------------|------------|
| Arguments | <i>name</i>       | A symbol.  |
|           | <i>class-name</i> | A string.  |
|           | <i>field-name</i> | A string.  |
|           | <i>static-p</i>   | A boolean. |
|           | <i>is-final</i>   | A boolean. |

Values      *name*

Description      The macro `define-field-accessor` defines a field accessor for a field in a Java class.

The arguments are interpreted as by `setup-field-accessor`.

Unlike `setup-field-accessor`, `define-field-accessor` does not look up anything. The accessor does the look up first time it is called, and signals an error if something failed. This error should be of type:

`java-class-error`

Failed to find the class.

`java-field-error`

Failed to find the field, or found the field but wrong *static-p* value.

**field-access-exception**

Got an exception trying to access the field.

Notes

1. In general, accessing fields should be avoided, because they are typically a less well-defined and implemented interface than methods, but sometimes it is necessary.
2. The importing interface generates appropriate **define-field-accessor** forms for public fields.

**setup-field-accessor**

## define-java-caller

## define-java-constructor

*Macros*

Summary

Define a Java caller, which is a function that calls a Java method or a constructor.

Package

**lw-ji**

Signature

**define-java-caller** *name class-name method-name &key signatures => result*

Signature

**define-java-constructor** *name class-name &key class-symbol signatures => result*

Arguments

*name* A symbol.

*class-name* A string.

*method-name* A string.

*signatures* A list of strings.

*class-symbol* A symbol.

Values

*result* *name* or **nil**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macros <code>define-java-caller</code> and <code>define-java-constructor</code> define a Java caller, which is a function that calls a Java method or a constructor. Once this the caller is defined, calls to <i>name</i> ultimately invoke the Java method or constructor.</p> <p><i>class-name</i> must be the full name of a Java class, in the correct case. The '.' in the name may be replaced by '/'.</p> <p><i>method-name</i> must be a public method name of the class, with the correct case.</p> <p><i>class-symbol</i>, when it is non-nil, must name a class. It creates a mapping from the class to the constructor info, which allow functions like <code>make-java-instance</code> and <code>create-instance-object</code> to construct a <code>jobject</code> for an instance of the class named by <i>class-symbol</i>.</p> <p>The effect of these macros is to set the symbol function of <i>name</i> to a function that calls the method in the class or the constructor of the class. When there is more than one method with the same name or more than one constructor (that is, it is overloaded), the function decides dynamically which of these to call, based on the arguments it gets.</p> <p>For a successful call to <i>name</i>, it needs to be called with the correct arguments for the Java method. For an ordinary method, this must include the object on which the method should be applied, followed by the arguments of the method. For static methods and constructors, the arguments to <i>name</i> are just the arguments to the method/constructor.</p> <p>For arguments of primitive type or a matching Java class (for example <code>Integer</code>), the Lisp argument must be either a Lisp object of matching type (see “Types and conversion between Lisp and Java” on page 198), or a <code>jobject</code> of the corresponding Java class. For strings (that is argument type <code>java.lang.String</code>) the argument must be a <code>string</code>, <code>nil</code>, or a <code>jobject</code> of type <code>java.lang.String</code>. For other non-primitive</p> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

types, the argument must be a `jobject` of the correct class or `nil`. `nil` is passed as Java `null` for non-primitive types.

If the return value type is a primitive type or `String`, the function converts the result of the method to the matching Lisp type before returning it. For other return types, the function returns a `jobject` representing the Java object, or `nil` if the method returned `null`. Constructors always return `jobjects`.

When the method is an ordinary method (not static and not constructor), the invocation is virtual (normal Java behavior), which means that if the object is of a subclass of the `classname` argument, it may invoke a method that is defined in a subclass of `classname`.

Unlike the functions `setup-java-caller` and `setup-java-constructor`, the macros `define-java-caller` and `define-java-constructor` do not do any actual lookup, they just set up the symbol function and therefore they do not require running Java to perform the definition. They are also recognized by the Editor as definer forms, so source finders like the Editor command `Find Source` can locate them. These macros are intended as the main method of defining callers. They are produced by the importing interface to actually define the callers.

For callers defined by these macros, the actual lookup happens the first time the function is invoked, or for `define-java-caller` by `verify-java-caller` or `verify-java-callers`. If the lookup fails during the function call, an error is signaled of type `java-class-error` (when the class cannot be found) or `java-method-error` (when the method cannot be found).

The macros (when successful) return `name`.

- Notes
1. There is no difference in performance between functions defined by these macros and functions defined by `setup-java-caller` and `setup-java-constructor`. If you use `setup-java-caller` and `setup-java-constructor` in a delivered application then extra machinery is retained.
  2. If you need several `define-java-caller` forms with the same class, consider using `define-java-callers`.
  3. If you need many `define-java-caller` forms with the same class, you may want to use the importing interface. Even if you want to define your own names for the callers, you can either pass `name-constructor` to the import function, or use `write-java-class-definitions-to-file` and edit the definitions that it generated (which saves typing the method names).
  4. For methods it is possible to use `verify-java-callers` or `verify-java-caller` at run time to check that the methods are found, which is a way of guarding against typing errors in entering the method name.
  5. There is no restriction on defining more than one caller for the same method or constructor.
  6. Unlike `setup-java-caller` and `setup-java-constructor`, the `name` argument is not evaluated.

## **define-java-callers**

*Macro*

Summary      Define multiple Java callers for methods in the same class.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |

| Description | <p>The macro <code>define-java-callers</code> defines multiple Java callers for methods in the same class.</p> <p><code>class-name</code> must specify a Java class by its full name.</p> <p>Each item of <code>method-specs</code> must be a list where the first element is a symbol (the Java caller name), the second element is a string (the method name) and optionally followed by keyword/value pairs for <code>define-java-caller</code>. <code>define-javacallers</code> processes each item by inserting the <code>class-name</code> after the Java caller name, and then using the result as the arguments to <code>define-java-caller</code>:</p> <pre>(define-java-callers class-name   (caller-name1 method-name1)   (caller-name2 method-name2)) =&gt; (progn   (define-java-caller caller-name1 class-name method- name1)   (define-java-caller caller-name2 class-name method- name2)   class-name)</pre> <p><code>define-javacallers</code> is a more compact way to write several methods for the same class, but functionally it is identical to using <code>define-java-caller</code> explicitly.</p> <p><code>define-javacallers</code> returns the <code>class-name</code>.</p> |           |

|                                   | A body of Lisp code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                   |                   |                                   |  |  |                      |
| Values                            | <code>name</code> A non-nil symbol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                   |                   |                                   |  |  |                      |
| Description                       | <p>The macro <code>define-lisp-proxy</code> defines a Lisp proxy, which means creating a Lisp proxy definition and attaching it to <code>name</code>, which can then be used to create Lisp proxies, which are Java proxies where methods invocation ends up calling Lisp functions.</p> <p><code>define-lisp-proxy</code> parses <i>interface-and-method-descs</i> to a proxy definition, and attaches it to <code>name</code>. This operation is a "load-time" operation: it does not require running Java, and does not create any proxy. The name can then be used at run time as argument to <code>make-lisp-proxy</code> or <code>make-lisp-proxy-with-overrides</code>, or to the Java method <code>com.lisp-works.LispCalls.createLispProxy</code>. The result of any these calls is a proxy that implements the interfaces listed in <i>interface-and-method-descs</i>, and can be used in Java whenever an object that implements any of these interfaces is required.</p> <p><i>interface-and-method-descs</i> describes the Java interfaces to implement and the Lisp functions to call. It is parsed as a body of Lisp forms.</p> <p>Each element in the list must be either a string which is the Java interface name, or a list where the <code>c1:car</code> is the Java interface name. Each item specifies a Java interface to imple-</p> |                   |                   |                                   |  |  |                      |

ment, except that one item (at most) may specify options relating to the whole proxy definition, by using a list starting with the keyword `:options` instead of giving an interface name.

When the item is a list starting with an interface name, the rest of the list are method specifications. Note that you do not need to have a method specification for each method of the interface.

Each method specification must be a list, where the first element is a string with the name of the Java method, and the second element is the symbol specifying what Lisp function to call for this method. The symbol specifies the function to call except when it is overridden (see below about "Overriding"). In some cases, you will want to always override the function to call (typically when you want to use a closure as the function), in which case the symbol can be and should be a keyword (which is ignored by the verifying functions), but does not have to be. See below for how the calling of the Lisp function is done.

The rest of the method specification can contain keyword/value pairs. Currently, the only supported keyword is `:with-user-data`, which takes a boolean value, overrides the default value of `:with-user-data` of the proxy definition. The default of `:with-user-data` of the definition defaults to `nil`, and can be changed in the `:options`. The value of `:with-user-data` specifies whether to pass the `user-data` of a proxy to the Lisp function.

The `:options` item is specified by an item in *interface-and-method-descs* where the `c1:car` is the keyword `:options`. The rest of the item is keyword/value pairs. The keywords currently supported are:

**`:default-function`**

Specifies the default function to call for methods which do not have a Lisp function. This function is applied to the arguments of

the method preceded by the *method-name*, and if `:default-function-with-user-data` is non-nil also with *user-data* preceding the *method-name*.

The default function can be overridden by `make-lisp-proxy` and `make-lisp-proxy-with-overrides`.

**`:default-function-with-user-data`**

A boolean specifying whether the *user-data* of a proxy should be passed when the default function is called. When it is non-nil, the *user-data* is passed as the first argument to the *default-function* (or the function that overrides it). The default value of

`:default-function-with-user-data` is `nil`.

**`:with-user-data`**

A boolean specifying whether the default for calling functions in the proxy definition is with *user-data* or not. Each method description can override it as described above. The default value of `:with-user-data` is `nil`.

**`:print-name`**

Must be a string or a symbol. Specifies the first part of the *print-name* of each proxy.

**`:jobject-scope`**

One of `:global`, `:local` or `nil`. This controls the scope of `jobject` arguments (that is, arguments that are not of primitive type or string). With the default value `:global`, `jobjects` are passed as global `jobjects` and can be used indefinitely. When `:jobject-scope` is `:local`, `jobjects` are passed as a local `jobject`, which means that they must

not be used outside the scope of the function that is invoked by the proxy. Using a local `:object` out of scope can cause the system to crash (rather than call `c1:error`). When `:object-scope` is `nil`, `objects` are not passed at all to the functions. Note that means that the number of arguments that the functions in the proxy receive is different when `:object-scope` is `nil`, because only arguments of primitive type or strings are passed.

If you use `:object-scope :local`, the function can convert it to global using `object-ensure-global`, and then it can be used out of scope.

The default value of `:object-scope` is `:global`.

## user-data

The `user-data` is set up for each individual proxy object by `make-lisp-proxy` or `make-lisp-proxy-with-overrides`, and thus allows you to associate each individual proxy with an arbitrary Lisp object. The proxy definition determines whether to use it when calling the Lisp functions in the proxy definition. The default value of `user-data` is `nil`, so if you want to use it you need to specify it by using `:with-user-data`, either in the `:options` which would give the default value for all calls in the definition, or in individual method specifications. When `user-data` is passed, it is always passed to the Lisp function as the first argument. Another way to individualize proxies is to use overriding, which also allows you to use closures.

## Overriding

When `make-lisp-proxy` or `make-lisp-proxy-with-overrides` make a proxy, they can specify overriding of some of the symbols in the proxy definition. Overriding here means mapping one symbol to another symbol or a function object. When a symbol is supposed to be called and it is overridden, the target of the mapping is called rather than the symbol. Note that the overriding is specific to each individual proxy rather to the proxy definition, and therefore you can have different proxies using the same proxy definition (and hence implementing the same interface(s)), but calling different Lisp functions. An advantage of overriding is that it allows you to use closures created at run time instead of symbols.

See the entry for `make-lisp-proxy` for how the overriding is created.

## Calling the Lisp function

After a proxy is created from a proxy definition, any invocation of a Java method on it (except the Object methods `toString`, `equals` and `hashCode`) enters Lisp.

When a method is invoked on a proxy (normally from Java, but can be done from Lisp too), the steps for invoking your Lisp function are:

1. Check whether the item in the *interface-and-method-descs* for the interface of the method contains a method specification with the *method-name* of the method.
2. Convert the Java method arguments to Lisp arguments where possible. See “Types and conversion between Lisp and Java” on page 198.

Note that if the first step above found a method specification, and it contains the keyword `:object-scope`, it affects the way non-primitive arguments are processed as described above.

**3. Calling the user code:**

- (i) If a method specification was found in the first step above:
  - a) Take the symbol from the method specification, then
  - b) Check whether the symbol is overridden, and if it is use the target as a function to call. Otherwise, check whether the symbol is fbound, and if it is use it as a function to call, then
  - c) If as a result of (b) there is a function to call, check whether it should be called with the *user-data*. If `:with-user-data` was used in the method specification then use its value, otherwise if `:with-user-data` was used in `:options` item use this value, otherwise default to `nil`, then
  - d) Apply the function: if using *user-data*, apply the function to the *user-data* followed by the Lisp arguments, otherwise apply the function to the Lisp arguments only.
- (ii) If the method-specific call in (i) did not happen (no method specification found, or the symbol is not fbound and not overridden), try to apply the default function:
  - a) If there is a default function, check whether it is overridden and if so use the target as the function to call. Otherwise use the *default-function* itself as the function to call, then
  - b) Check whether need to pass *user-data*, which is specified by the `:default-function-with-user-data` in the `:options` item, then
  - c) Apply the function: if *user-data* needs to be used, apply the function to the *user-data*, *method-name* and the Lisp arguments. Otherwise apply the function to the *method-name* and Lisp arguments.
- (iii) If the calls in (i) and (ii) did not happen, an error is signaled. See handling of errors below.

4. Return a value: currently, if the user function returned a Java object (a `jobject` or an instance of `standard-java-object`), it is returned without checking. Otherwise, try to convert it to the appropriate Java object and return it. Otherwise, report it by calling the `java-to-lisp-debugger-hook` (see `init-java-interface`) with a `cl:simple-error` condition and return a default value from the Java method invocation, which is 0 for primitive types or `null` for other types.

## Throwing out and error handling

The call to the Lisp function is wrapped dynamically such that any throw from it is blocked, and the default value as in the last step above is returned.

In addition, there is a debugger wrapper (using `with-debugger-wrapper`) which calls the `java-to-lisp-debugger-hook` (see `init-java-interface`) with the condition and then calls `cl:abort`. If this abort is not caught by your `cl:abort` restart, it is handled by the "throwing blocker" from the previous paragraph, that is the Java method returns 0 or `null`.

## Verification

The verification functions `verify-lisp-proxies` and `verify-lisp-proxy` are provided to allow you to do some checking of the correctness of your proxy definition. Two things can be verified:

- That the symbols to be called in the proxy definition are fbound. In principle this check could happen at load-time, but that would enforce defining the functions before the proxy. The verification allows you to define the proxies and functions in any order, and then verify all the definitions, for example just before delivery.

- Check that all methods that are declared in the Java interfaces have a *method-desc*, and report those that do not. This requires running Java.

Note that neither of these issues is actually an error, because the default function can handle them. However it is useful to check them in case you did miss something.

## Performance issues

There is a little overhead associated with using `setup-lisp-proxy` as opposed to `define-lisp-proxy`, both in the size of the delivered application (very small) and in run time, but the difference is not large enough to prevent using `setup-lisp-proxy` when it is appropriate.

There is an overhead associated with initializing a proxy definition. It is therefore a bad idea to use `setup-lisp-proxy` many times.

Overrides and using multiple interfaces add a negligible overhead.

`:object-scope` with `nil` or `:local` are useful optimizations. In proxies that are invoked infrequently, say less than 10 times each second, the difference is probably insignificant, but it is useful for proxies that are called repeatedly by Java code. For example, if you implement the interface

`"java.io.FilenameFilter"` to pass to  
`"java.io.File.list"` on large directories, using `:object-scope :local` or `nil` will reduce the overhead significantly.

| Description            | <p>The function <code>ensure-lisp-classes-from-tree</code> creates a class for <i>lisp-name</i>, and potentially some or all the super-classes as needed based on the tree. Note that all references to “class” here are to Lisp classes. <code>ensure-lisp-classes-from-tree</code> does not actually know anything about Java.</p> <p><code>ensure-lisp-classes-from-tree</code> appears the output of the importing interface functions, where it is called with the output of <code>get-superclass-and-interfaces-tree</code>. Users can use it as well, but normally using plain <code>defclass</code> is much more appropriate.</p> <p><i>java-class-tree</i> is a tree representing the hierarchy of the Java classes. The structure of the tree is described in the entry for <code>get-superclass-and-interfaces-tree</code>. In general it is assumed that this tree was generated by <code>get-superclass-and-interfaces-tree</code>, but you can generate it yourself if</p> |                  |                     |                        |         |                |                        |

you find it useful, but normally simply using `defclass` to define the classes you want is better.

`force-p` controls whether to force classes to exist or not.

The processing of a node in the tree when `force-p` is `nil` is as follows (note that the `java-class-tree` argument is the first node):

1. Find the symbol corresponding to the class. For the first node, this is the `lisp-name` argument. For other nodes, it first checks whether `record-java-class-lisp-symbol` recorded the `java-class-name` to `lisp-name` mapping, and use it if it did. If not, `ensure-lisp-classes-from-tree` skips this node and use instead the superclass node.
2. Once the symbol is found, `ensure-lisp-classes-from-tree` processes the nodes of the superclass and the nodes of the interfaces, each one of which returns a class, and construct the superclasses list from the result. It remove duplicates from the list, which can happen because interfaces can be implemented by more than one route.
3. Once it got the superclasses, except for the first node, `ensure-lisp-classes-from-tree` checks whether the symbol has got a class definition, and if this class definition inherit from all the superclasses. If it does, it returns this class as the result. If a class is found but is not inheriting all the superclasses, `ensure-lisp-classes-from-tree` redefine it to inherit all the superclasses (ignoring the existing definition), and return it. If the class is not found, `ensure-lisp-classes-from-tree` skips this node and use instead the superclass node.

For the first node, `ensure-lisp-classes-from-tree` always creates the class.

If `force-p` is true, then `ensure-lisp-classes-from-tree` never fails for any node. Instead, in step 1.) when it does not find the symbol it generates a symbol in the same way that

`generate-javascript-definitions` does by default, and in step 3.) if there is no class it creates it.

- Notes
1. `ensure-lisp-classes-from-tree` does not need running Java.
  2. The main purpose of `ensure-lisp-classes-from-tree` is to create the needed class(es) at load-time without a need for running Java. It is not intended to be used at run time.
  3. `ensure-lisp-classes-from-tree` uses `clos:ensure-class` to create or redefine classes, so requires keeping CLOS in a delivered image (as described in the *LispWorks Delivery User Guide*).
  4. When the `java-class-tree` argument matches the Java hierarchy, as it is when it is the result of `get-superclass-and-interfaces-tree`, if `force-p` is true `ensure-lisp-classes-from-tree` generates a full hierarchy with a CLOS class matching each Java class. with `force-p nil`, at least `standard-java-object` will always be in the hierarchy, plus any classes that were define by the importing interface or recorded by the user using `record-javaclass-lisp-symbol`.

| Description | <p>The function <code>ensure-supers-contain-java.lang.object</code> checks that at least one of the symbols in <i>super-symbols</i> names a subclass of <code>standard-java-object</code> (or <code>standard-java-object</code> itself), otherwise it signals an error reporting that the superclasses for <i>lisp-name</i> do not have a subclass of <code>standard-java-object</code>.</p> <p><code>intern-and-export-list</code> is a utility function that is used by the importing interface when <i>lisp-supers</i> is passed to ensure at load-time that the supers contain a subclass of <code>standard-java-object</code>.</p> |                    |

| Arguments              | <code>class-sym-or-string</code> A symbol or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values                 | <code>result</code> A <code>jobject</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description            | <p>The function <code>find-java-class</code> finds a Java class and returns a <code>jobject</code> representing it.</p> <p>If <code>class-sym-or-string</code> is a string, it should be the full name of class. <code>find-java-class</code> allows the '.' in the names to be replaced by '/' (which is how the class is actually looked up). <code>find-java-class</code> also recognizes class names of primitives (for example, "int"), and can also find classes for arrays, using the internal syntax with leading '[' character(s).</p> <p>If <code>class-sym-or-string</code> is a symbol, it can be a keyword specifying a primitive class (see the table in “Types and conversion between Lisp and Java” on page 198), one of <code>:object</code> or <code>t</code> to specify <code>java.lang.Object</code>, <code>:string</code> to specify <code>java.lang.String</code>, or a symbol which is set to a string, in which case the value is used to search for a class.</p> <p>If <code>find-java-class</code> finds the Java class, it returns a <code>jobject</code> representing it.</p> <p>Otherwise, if <code>errorp</code> is non-nil it signals an error, otherwise it returns <code>nil</code>. The default value of <code>errorp</code> is <code>t</code>.</p> |
| Notes                  | For most of the Java interface, you do not actually need to find the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Values      | <p><i>list-of-definitions</i> A list.</p> <p><i>lisp-name-symbol</i> A symbol.</p> <p><i>package-name-string</i><br/>A package name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>The function <code>generate-java-class-definitions</code> returns a list of forms which are definitions of Java callers that call the public methods (including constructors) of the class specified by <i>java-class-name</i>, and accessors for public fields. These include inherited methods and fields.</p> <p><code>generate-java-class-definitions</code> is normally used indirectly by using <code>import-java-class-definitions</code>, but can also be used directly. <code>write-java-class-definitions-to-file</code> and <code>write-java-class-definitions-to-stream</code> do the same processing as <code>generate-java-class-definitions</code>, and then generate output based on the result.</p> <p><i>java-class-name</i> must name a Java class, and it must be the precise full name, for example "<code>java.io.File</code>", "<code>android.view.View</code>".</p> <p>If <i>lisp-name</i> is supplied it must be a Lisp symbol. In this case it specifies the package to intern the names of definitions in,</p> |

and if a CLOS class is defined, the name of this class. It is also automatically defined as a constant with a value the *java-class-name*. *lisp-name* can also be `nil`.

If *lisp-name* is not supplied, the system creates a Lisp symbol based on the *java-class-name*. Note that this is different from passing `nil`, because in the latter case *lisp-name* stays `nil`.

*package-name* is used only if *lisp-name* is supplied as `nil`, to specify the package where the names of the definitions are interned. It must be a string containing the package name (in the desired case). The package is created if it does not exist already. If *lisp-name* is `nil` and *package-name* is `nil` or not supplied, the current package is used.

*prefix*, if supplied, specifies a prefix to use for the names of the definitions. If *prefix* is not supplied or is `nil`, the name of the Java class without the package part is uppercased and used as the *prefix* (for example for "java.io.File" the *prefix* is "FILE"). The *prefix* is passed to the *name-constructor* to construct names for the Java callers.

If *name-constructor* is supplied, it must be a function taking two string arguments: the *prefix* and the name of the Java method or field that the Java caller is going to call or access (for constructors, the string "new" is passed as the method name). It must return a string which is then interned (without changing the case) in the package to create the symbol that is used as the name of the caller. The *name-constructor* defaults to a function (`default-name-constructor`) that concatenates the *prefix* as it is, a dot and uppercase of the method/field name. For example, for the method "exists" in the Java class "java.io.File", the default name constructor with the default *prefix* would generate "FILE.EXISTS".

*export-p* controls whether all the Java callers are exported from the package. If it is `t` all the Java callers are exported, otherwise they are not. The default of *export-p* is `t`.

`create-defpackage` controls what form to generate to do the package manipulation. With the default, `generate-java-class-definitions` generates a form that checks that the package exists, otherwise creates it, and if `export-p` is `t`, a form that exports all the symbols. If `create-defpackage` is non-nil, `generate-java-class-definitions` generates a `defpackage` form instead. The default value of `create-defpackage` is `nil`.

**Note:** the reason the `create-defpackage` defaults to `nil` is that the `defpackage` form would contain only the symbols that were defined by the importing, which would be wrong if the package needs to export other symbols too, which is quite likely with the default settings (because other classes in the same Java package will default to use the same Lisp package). `create-defpackage` is useful when you want to create a package that exports only the definitions for a single Java class.

`lisp-supers` and `lisp-class-p` control whether a CLOS class is defined for the Java class. By default, no CLOS class is defined. See in “Creating CLOS class” on page 1244.

The generation of the Java callers and accessors by `generate-java-class-definitions` is as follows:

1. Based on the arguments as described above, it determines the package, `prefix` and `name-constructor` to use, and whether it has a `lisp-name` and needs to define a CLOS class. It then finds the definition of the Java class.
2. It uses Java methods to find the names of all the public methods, constructors and fields of the class (including inherited ordinary methods and fields).
3. For each name, it calls the `name-constructor` with the `prefix` and the name to generate a symbol name which is then interned in the package to generate a symbol. It then generates a form where the operator is one of the macros

`define-javascript-caller`, `define-javascript-constructor`, or `define-field-accessor`, as appropriate, using the symbol as the name.

For example, with the defaults generating for `"java.io.File"`, the constructor would be defined by

```
(define-javascript-constructor FILE.NEW  
"java/io/File")
```

The caller for the method `"exists"` would be defined by:

```
(define-javascript FILE.EXISTS "java/io/File"  
"exists")
```

the accessor for the field `"separator"` would be defined by:

```
(define-field-accessor file.separator  
"java/io/File" "separator" t t)
```

Note that `generate-javascript-class-definitions` uses `'/'` rather than `'.'` as separator between the components. The definer macros accept both `'/'` and `'.'` as separators. The actual generated forms may contain additional keywords. Currently methods and constructors have the signatures.

4. `generate-javascript-class-definitions` also identifies pairs of methods where one has the name `set<something>` and the other has the name `get<something>` or `is<something>`, which are assumed to be setter and getter for the same field. It then generates a `c1:setf` definition to allow using `c1:setf` on the symbol corresponding to `get<something>` or `is<something>` name to call the `set<something>` method.
5. For fields, `generate-javascript-class-definitions` also generates a symbol macro with a name that is the symbol name preceded and followed by the `*` character, and allows getting and the setting the field using this symbol.

The first return value of `generate-java-class-definitions` is a list of forms. The list contains the following forms in this order:

- Package manipulation forms (ensuring the package exist and exporting if required) either as `defpackage` forms or forms that explicitly ensure the existence of the package and do any exporting.
- If there is a *lisp-name*, define it as constant with the class name as value, and record the relation between the Java class name and the symbol (this is used by `create-instance-from-jobject`).
- All the Java callers and accessors that were defined as described in the previous paragraph.
- If a CLOS class is needed, a form to create the class.

`generate-java-class-definitions` also returns the *lisp-name* (supplied or generated) as second return value, and the package name of the package that it used as third value.

## Creating CLOS class

**Note:** see the discussion “CLOS partial integration” on page 218.

The arguments *lisp-class-p*, *lisp-supers* and *lisp-name* control whether the importing also defines a class. *lisp-name* and either *lisp-supers* or *lisp-class-p* must be non-nil to generate a Lisp class.

*lisp-name*, when non-nil, defines the name of the class. Note that by default *lisp-name* is not `nil`, because `generate-java-class-definitions` generates a symbol if *lisp-name* is not supplied.

If *lisp-supers* is supplied and non-nil (and *lisp-name* is non-nil) a class is created, using a plain `defclass` form, and the value *lisp-class-p* is ignored. *lisp-supers* must be a list of symbols naming classes, of which at least one is `standard-java-`

`object` or a subclass of it. This list defines the superclasses of the class that is defined.

If `lisp-class-p` is non-nil and `lisp-supers` is `nil` (and `lisp-name` is non-nil) a class is created using `ensure-lisp-classes-from-tree`. If `lisp-class-p` is the keyword `:complete`, the `force-p` argument is passed is `t`, otherwise it is `nil`. See `ensure-lisp-classes-from-tree` for details.

`generate-java-class-definitions` returns three arguments: the list of definitions, the `lisp-name` and the package name.

|          |                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>generate-java-class-definitions</code> require running Java Virtual Machine, and access to the class definition via the <code>java.lang.reflect</code> package functionality.       |

| get-host-java-virtual-machine |                  | <i>Function</i>                                                                                                                                                                                 |
|-------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                       |                  | Return the host Java virtual machine in a dynamic library loaded by Java.                                                                                                                       |
| Package                       |                  | <code>lw-ji</code>                                                                                                                                                                              |
| Signature                     |                  | <code>get-host-java-virtual-machine =&gt; jvm</code>                                                                                                                                            |
| Values                        | <code>jvm</code> | A <code>java-vm-poi</code> or <code>nil</code> .                                                                                                                                                |
| Description                   |                  | The function <code>get-host-java-virtual-machine</code> returns the host Java virtual machine when it is called in a dynamic library that was delivered with a call <code>setup-deliver-</code> |

`dynamic-library-for-java`, and the dynamic library was loaded by Java. In all other circumstances it returns `nil`.

If the initialization of the Java interface is synchronous, which is determined the `asynchronous` argument of `setup-deliver-dynamic-library-for-java` and is the default, then during the call to the deliver startup function (the first argument of `deliver`), `get-host-java-virtual-machine` still returns `nil`. It is guaranteed to return the correct value only when the `function` argument of `setup-deliver-dynamic-library-for-java` (if any) is called. In the asynchronous case, `get-host-java-virtual-machine` always returns the correct value.

The result `jvm`, when it is not `nil`, is an object of type `java-vm-poi`.

`get-host-java-virtual-machine` is useful as a predicate to determine if the library was loaded by Java or non-Java code.

#### Notes

`get-host-java-virtual-machine` can find the virtual machine because Java calls `JNI_OnLoad` with it. If a non-Java code calls `JNI_OnLoad` with something else, then `get-host-java-virtual-machine` will return that something else.

When `init-java-interface` is called without a specified Java virtual machine, it uses `get-host-java-virtual-machine` to try to find the current one.

## get-java-virtual-machine

## *Function*

#### Summary

If a Java virtual machine has started, return it.

#### Package

`lw-ji`

| Arguments   | None.                                                                                                                                                                                                                                                                              |
| Values      | <code>java-virtual-machine</code> A <code>java-vm-poi</code> .                                                                                                                                                                                                                     |
| Description | The function <code>get-java-virtual-machine</code> returns the Java virtual machine if it has started. If LispWorks already knows what the virtual machine is, it just returns it. Otherwise, it tries to use the C function <code>JNI_GetCreatedJavaVMs</code> to try to find it. |

|             | <code>caller</code>                                                                                                                                                                                                                                                                                                                                                            | A Lisp object.           |
| Values      | <code>jobject</code>                                                                                                                                                                                                                                                                                                                                                           | A <code>jobject</code> . |
| Description | The functions <code>get-jobject</code> and <code>ensure-is-jobject</code> both get the <code>jobject</code> of the <code>object</code> argument. If <code>object</code> is already a <code>jobject</code> it is simply returned. If it is an instance of <code>standard-java-object</code> and has an associated <code>jobject</code> , this <code>jobject</code> is returned. |                          |

Otherwise, `get-object` returns `nil` but `ensure-is-object` signals an error. `ensure-is-object` uses *caller* in the error message to identify where the error occurred.

|          |                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>get-object</code> is the predicate to check whether an object is a Java object.                                                                  |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>get-primitive-array-region</code> copies from a Java array of primitive type to a buffer specified by a foreign pointer.</p> <p>The function <code>set-primitive-array-region</code> copies from a buffer specified by a foreign pointer to a Java array of primitive type.</p> <p><i>buffer</i>, if supplied, must be a foreign pointer pointing to a suitable buffer, which means large enough to receive the data in <code>get-primitive-array-region</code>, or containing the desired data in <code>set-primitive-array-region</code>.</p> <p><i>start</i> and <i>end</i> are bounding index designators for <i>array</i>, specifying the region to copy in number of elements.</p> <p><i>buffer-size</i> is used only when <i>buffer</i> is also supplied. <i>buffer-size</i> specifies the number of bytes to copy into <i>buffer</i>. If copying the required number of elements requires more bytes, <code>get-primitive-array-region</code> signals an error. Note that <i>buffer-size</i> is specified in bytes, while <i>start</i> and <i>end</i> are specified in elements.</p> <p>If <i>buffer</i> is not supplied to <code>get-primitive-array-region</code> it creates a buffer of the correct size using <code>fli:allocate-foreign-object</code>. In this case you will need to free the buffer using <code>fli:free-foreign-object</code> when the program has finished with it.</p> <p><code>get-primitive-array-region</code> copies the required number of elements into the buffer, and returns two values: the target buffer (either the <i>buffer</i> argument or the new buffer) and the <i>foreign-type</i> corresponding to the Java primitive type (one of <code>jbyte</code>, <code>jshort</code>, <code>jint</code>, <code>jlong</code>, <code>jfloat</code>, <code>jdouble</code>, <code>jboolean</code> and <code>jchar</code>).</p> <p><code>set-primitive-array-region</code> copies the required number of elements from <i>buffer</i> to <i>array</i>, and returns two values: <i>t</i> and the foreign type.</p> |

| Notes    | These functions are useful when you need to pass the data to foreign code. If you need the data in Lisp, use <code>lisp-array-to-primitive-array</code> or <code>primitive-array-to-lisp-array</code> instead. |

| Arguments                                 | <code>java-class</code> A <code>jobject</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values                                    | <code>java-class-tree</code> A tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description                               | The function <code>get-superclass-and-interfaces-tree</code> takes a Java class and returns of its superclasses and implemented interfaces. It is used by the importing interface to generate a tree which is then output as argument to <code>ensure-lisp-classes-from-tree</code> . It may be useful on its own, as a quick way of finding the tree for a class.<br><br><code>java-class</code> must be a Java class, that is a <code>jobject</code> corresponding to a class. Typically that would be the result of <code>find-java-class</code> , but it can be the result of your calls to Java methods. Using the Java methods "getInterfaces", "getSuperclass" and "getName" in the Java class "java.lang.Class", <code>get-superclass-and-interfaces-tree</code> constructs a complete |

tree of the superclasses and implemented interfaces of the class and its superclasses.

Each node in the tree is a vector of three elements:

- 0) The full name of the class as a string
  - 1) A node for the superclass (in Java terminology, the one it extends), or `nil` if there is no superclass (for `java.lang.Object` and interfaces).
  - 2) A list of nodes corresponding to the interfaces that the class implements.

`get-superclass-and-interfaces-tree` returns the node for the class itself.

## **import-java-class-definitions** *Macro*

**Summary** Generates all the definitions for a Java class.

## Package **lw-ji**

**Signature** `import-javaclass-definitions java-class-name &key lisp-class-p lisp-name export-p package-name name-constructor lisp-supers => lisp-name-symbol`

Arguments      *java-class-name*    A string.

## *lisp-class-n* A generalized boolean

*lisp-name*      A symbol

export-*p* A generalized boolean

*package-name* A package designator

*name-constructor* A function designator

## *lisp-supers* A list of symbols

| Description | <p>The macro <code>import-java-class-definitions</code> generates all the definitions for the class <code>java-class-name</code>, and wraps <code>c1:progn</code> around them, and returns this from the macroexpansion. Therefore evaluation of an <code>import-java-class-definitions</code> form defines all the callers for <code>java-class-name</code>. <code>java-class-name</code> name must name a Java Class, and it must be the precise full name.</p> <p>The generation of the definitions is done by <code>generate-java-class-definitions</code>, and all the keywords are passed to it. See the entry for <code>generate-java-class-definitions</code> for the effects of the keywords.</p> <p>During macroexpansion, <code>import-java-class-definitions</code> needs to be able to find the class definitions, for which it needs running Java, which means a Java Virtual Machine running and the class being accessible. The evaluation of the definitions does not require Java. Thus if you compile a file containing an <code>import-java-class-definitions</code> form, the binary file can be loaded without Java, but the compilation needs running Java, and loading the source file also requires running Java.</p> <p>The returned value <i>lisp-name-symbol</i> is the Lisp name (which is <i>lisp-name</i>, or is generated by <code>generate-java-class-definitions</code> if <i>lisp-name</i> was not supplied).</p> <p>See “Importing classes” on page 201 for discussion.</p> |
| Notes       | <ol style="list-style-type: none"><li>1. You can avoid the need for running Java during compilation by writing the definitions using the writers (<code>write-java-class-definitions-to-file</code> or <code>write-java-class-definitions-to-stream</code>) once, and incorporate the output into your sources.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

2. Even when you use `import-java-class-definitions`, it is probably useful to look at the output of the writers to have a better idea what is actually being generated.

Examples      (`import-java-class-definitions "java.io.File"`)

See also      `generate-java-class-definitions`  
`write-java-class-definitions-to-file`  
`write-java-class-definitions-to-stream`  
“Importing classes” on page 201

## init-java-interface

### setup-java-interface-callbacks

*Functions*

Summary      Initializes the Java interface.

Package      `lw-ji`

Signature      `init-java-interface &key jvm-library-path java-class-path  
option-strings jni-env-finder java-virtual-machine class-finder class-loader-finder java-to-lisp-debugger-hook report-error-to-java-host  
send-message-to-java-host => result`  
`setup-java-interface-callbacks &key class-finder java-to-lisp-debugger-hook report-error-to-java-host send-message-to-java-host => t`

Arguments      *jvm-library-path* A string, `t` or `nil`.

*java-class-path* A string or a list of strings.

*option-strings* A list.

*jni-env-finder* A function designator, or `nil`.

*java-virtual-machine*

A foreign pointer of type `java-vm-poi`, or `t`.

*class-finder* A function designator or `nil`.

*class-loader-finder* A function designator or `nil`.

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <code>t</code> or the keyword <code>:no-java-to-lisp</code> . |
| Description | <p>The function <code>init-java-interface</code> needs to be called before using any of the run time part of the Java interface. That includes the interface functions that are documented as requiring Java, and any of the user-defined callers. The definers in general do not need running Java, but the importing interface does.</p> <p><b>Note:</b> On Android and in dynamic libraries that were delivered with <code>setup-deliver-dynamic-library-for-java</code> with <code>init-java</code> true (the default), <code>init-java-interface</code> is called automatically by the system initialization, so you do not need to (and must not) call it.</p> <p><code>init-java-interface</code> may be used to first initialize the Java Virtual Machine (JVM) or can be called with the JVM already running.</p> |                                                               |

## Initializing the virtual machine

If `init-java-interface` needs to initialize the JVM, it must be called with `jvm-library-path` either `t` or the path of a dynamic library, and `jni-env-finder` must be `nil`. When `jvm-library-path` is `t`, `init-java-interface` uses a default JVM library path, which is currently `"/System/Library/Frameworks/JavaVM.framework/JavaVM"` on Mac OS X and `"-ljvm"` on other Unix variants. On Windows, `init-java-interface` checks the registry for the location of the JVM library, using the keys that Oracle document in *Java 2 Runtime*

*Environment for Microsoft Windows.* The library must implement the JVM, which means exporting the JNI functions, and to be able to find any supporting files that it may need. It loads this library by `fli:register-module`, and then initializes it using `JNI_CreateJavaVM`. The keyword arguments `java-class-path` and `option-strings` can be used to pass options to `JNI_CreateJavaVM`. Except on Mac OS X, passing `jvm-library-path` t can work only if the library path contains the JVM library.

`java-class-path` specifies the class path(s) for additional classes on top of the system ones. It is used to specify the `-Djava.class.path` option. If `java-class-path` is a string, it is passed as is, and may contain more than path separated by the appropriate separator (#\: on Unix, #\; on Windows), for example `"/myhomedir/myjavaclass;/systemdir/systemjavaclasses/"`. If it is a list, each string should be a path. Each path needs to specify either a directory containing JAR files, or a full path of a JAR file.

If you want to make calls from Java to Lisp, you will need to have the Java class `com.lispworks.LispCalls`. `com.lispworks.LispCalls` is defined in the JAR file `lispcalls.jar` which is part of the LispWorks distribution in the `etc` directory, that is (`lispworks-file "etc/lispcalls.jar"`), so this JAR file will have to be on the path. If you develop for Android and want to import Android classes, you will need the `android.jar` on the path too.

`option-strings` can be used to pass options to `JNI_CreateJavaVM`. Each element of `option-strings` is either a string or a cons of two strings. An element which is a string is passed as the option string (slot `optionString` of the `JavaVMOption` C struct). For a cons, the car is passed as the option string, and the cdr as the extra info (slot `extraInfo` in the `JavaVMOption`). Note that that you should not use the option `-Djava.class.path` when using the `java-class-path` argument.

*java-class-path* and *option-strings* are ignored when `init-java-interface` is called after the JVM started.

## Calling with JVM already running

If `init-java-interface` is called with the JVM already running, then *jvm-library-path* must be `nil`, and either *jni-env-finder* or *java-virtual-machine* must be supplied as non-`nil`, except when called inside a dynamic library delivered with `setup-deliver-dynamic-library-for-java`, when all arguments can be `nil`.

If *jni-env-finder* is non-`nil` then it must be a function of no arguments that returns a pointer to the JNI environment for the current thread. The result of the finder must be a foreign pointer of type *jni-env-poi*, corresponding to the C pointer `JNIEnv*`. The finder function needs to cope with being called on any thread and the result needs to be valid until that thread dies, at which point implementing code must deal with eliminating it. In general, this function needs to know how to find the Java virtual machine, and then use the JNI functions `AttachCurrentThread` OR `GetEnv`.

If *jni-env-finder* is `nil`, then *java-virtual-machine* is used. If *java-virtual-machine* is `t`, LispWorks tried to find the Java virtual machine by first calling `get-host-java-virtual-machine`, and if this returns `nil`, by calling `JNI_GetCreatedJavaVMs`. Otherwise, *java-virtual-machine* is used as the virtual machine and must be a foreign pointer of type *java-vm-poi*, corresponding to the C type `JavaVM*`.

When running in a dynamic library delivered with `setup-deliver-dynamic-library-for-java`, `init-java-interface` should be called with *jvm-library-path*, *jni-env-finder* and *java-virtual-machine* all `nil` because the Java virtual machine is obtained using `get-host-java-virtual-machine` in this case.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes                  | <p>The simple option when the JVM is already running is just passing <code>java-virtual-machine t</code>. However, the function that the system uses, <code>JNI_GetCreatedJavaVMs</code>, is a relic from the time when Java allowed more than one Java VM in each process, which it no longer allows. So in principle some day it may be eliminated (Android already does not define it, but on Android the system calls <code>init-java-interface</code> with <code>jni-env-finder</code>, so this does not matter). On the other hand it is documented in the latest version (8) without any indication that it is deprecated.</p> |
|                        | <p>You may have a pointer to the Java VM to pass to <code>init-java-interface</code> either because you got it from code that started the Java VM (by <code>JNI_CreateJavaVM</code>), or by exporting <code>JNI_OnLoad</code> from a dynamic library. However, it is not a good idea to export <code>JNI_OnLoad</code> as a foreign callable from LispWorks when it is delivered as a dynamic library, because it will have to wait until LispWorks finished initialization. See “Loading a LispWorks dynamic library into Java” on page 217.</p>                                                                                     |
|                        | <p>By default, <code>setup-deliver-dynamic-library-for-java</code> sets up automatic initialization of the Java interface on startup. You need (and can call) <code>init-java-interface</code> in such a dynamic library only if you passed <code>nil</code> for the <code>init-java</code> argument to <code>setup-deliver-dynamic-library-for-java</code>.</p>                                                                                                                                                                                                                                                                      |
|                        | <p>If you call <code>init-java-interface</code> with <code>jvm-library-path</code>, <code>jni-env-finder</code> and <code>java-virtual-machine</code> all <code>nil</code> and <code>get-host-java-virtual-machine</code> returns <code>nil</code>, then <code>init-java-interface</code> returns <code>nil</code> rather than give an error.</p>                                                                                                                                                                                                                                                                                     |
| Description<br>(cont.) | <p><code>class-finder</code> specifies a class finder function to be used if the normal search fails. It must be a function taking a string argument, and return a <code>jobject</code> representing a class for this string (for example, a caller for the method <code>java.lang.Class.forName</code> does the right thing). It is useful when the application knows how to find classes which are not visible from the system class loader. On Android, <code>class-</code></p>                                                                                                                                                    |

*finder* is passed with a function that calls `java.lang.Class.forName` with the application Class loader, which will find all classes in the application.

*class-loader-finder* is used when initializing the LispCalls. If it is non-nil, it must be a function of no arguments that returns a ClassLoader `jobject`. It is called once during initialization, and the result is stored to be used to find the interfaces when initializing a proxy definition. On Android, it is passed with a function that returns the application class finder. You need to be a Java expert to use this option.

*java-to-lisp-debugger-hook*, when supplied, must be either a function of one argument or `nil`. When it is a function, it will be called when the debugger is invoked inside a call from Java to Lisp. The argument is a `c1:condition` object describing the problem. The function needs to do something to inform the user of the problem but not actually interactively, and return. The caller will then return a default value to Java. By default there is a hook that logs a bug form (by `log-bug-form`) and prints a message to the console. On Android, it is set to a function that logs the error and then invokes the user Java error reporters (set in Java by `com.lispworks.Manager.setErrorReporter` and `com.lispworks.Manager.setGuiErrorReporter`, see the entry for `setErrorReporter`).

*report-error-to-java-host*, when supplied, must be a function of two arguments, both of which are strings. When it is passed, if the function `report-error-to-java-host` is called it uses this function to actually do the report. The first argument is assumed to be the error string and the second a filename where there is a bug form, or `nil`. The function should report to the Java host, whatever that actually means. This keyword is used by the Android interface to set a function that calls into the Android Java code and invokes the same user Java error reporters that are used for the debugger hook above.

The system does not call `report-error-to-java-host` itself, so the context in which the function may be called is defined by your calls to it. However, it is intended to be used in error handlers, which means it should be able to cope with any context. The default function just prints to `cl:*terminal-io*`, which may be useful enough when just debugging.

`send-message-to-java-host`, when supplied, must be a function of two arguments: a string which is the message and a keyword, which tells it how to deal with it. The intent is to modify the "messages output" as described for the `where-keyword` in `send-message-to-java-host`. The meaning of "messages output" and the actual behavior is up to the function. On Android it is supplied a function that ends up calling the method `com.LispWorks.Manager.addMessage`. The default function checks the keyword and then writes the string to `cl:*terminal-io*`, which is probably good enough for testing purposes.

`init-java-interface` returns either `t` for success, or `:no-java-to-lisp` when it is successful but failed to initialize Java-to-Lisp calls, so you cannot call from Java to Lisp or use Lisp proxies. This failure would normally mean that it failed to find the class `com.lispworks.LispCalls`.

`setup-java-interface-callbacks` can be called after `init-java-interface` was called to change the values of `class-finder`, `java-to-lisp-debugger-hook`, `report-error-to-java-host` or `send-message-to-java-host`. This is useful in the situations where LispWorks performs the call to `init-java-interface`, which happens in Android and in a dynamic library delivered with `setup-deliver-dynamic-library-for-java`.

|             | <i>new-value</i> | A valid element for <i>array</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values      | <i>element</i>   | A Lisp object, a <code>jobject</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description |                  | <p>The function <code>jaref</code> reads and sets the value of an element in the Java array <i>array</i>.</p> <p>Each of the <i>indices</i> must be an integer in the right range, which means greater than or equal to 0, and less than than the length of the sub-array ("current array" below) for which they are used. There must be at least one index, and the number of indices must be smaller or equal to the array rank (that is, the number of dimensions) of <i>array</i>.</p> <p><i>new-value</i> must be a valid value to store in <i>array</i>. It has the same restrictions as <i>new-value</i> in <code>(setf jvref)</code>. See the discussion in <code>jvref</code> for details.</p> <p>The operation of <code>jaref</code> and <code>(setf jaref)</code> is as follows: For each index except the last, load the element from the "current array", which is the array itself for the first index or the element that was loaded for the previous index. When reaching the last index, <code>jaref</code> and <code>(setf jaref)</code> get or set the element in the "current array" the same way that <code>jvref</code> does. Note that this means that if there are less indices than number of the dimensions of the array, the access will be for a sub-array rather than actual element.</p> |
| Notes       |                  | <p>Because <code>jaref</code> needs to load the sub-srray for each index except the last, repeated calls to <code>jaref</code> for elements inside the same array are wasteful. It is much more efficient to get the sub-array and access it using <code>jvref</code>, or the multiple access functions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## **java-array-error** *Condition*

Summary      An abstract class, meaning that it is not signaled. Its readers can be used to access the subclasses.

Package      `lw-ji`

Superclasses      [java-interface-error](#)

Subclasses      [java-array-simple-error](#)  
[java-out-of-bounds-error](#)  
[java-storing-wrong-type-error](#)

Readers      [java-array-error-caller](#)  
[java-array-error-array](#)

Description      The condition class `java-array-error` is an abstract class, meaning that it is not signaled. Its readers can be used to access the subclasses.

## **java-array-indices-error** *Condition*

Summary      Conditions signaled by `jaref` or (`setf jaref`) when either too many indices are supplied for the array, or when a subarray is `null`.

Package      `lw-ji`

Superclasses      [java-array-simple-error](#)

Subclasses      None.

**java-array-length***Function*

|             |                                                                                                                                                                                                                                                                                                                                                 |  |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Returns the length of a Java array.                                                                                                                                                                                                                                                                                                             |  |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                                                                                                                                              |  |
| Signature   | <code>java-array-length object =&gt; result</code>                                                                                                                                                                                                                                                                                              |  |
| Arguments   | <i>object</i> A Java object.                                                                                                                                                                                                                                                                                                                    |  |
| Values      | <i>result</i> A non-negative integer or <code>nil</code> .                                                                                                                                                                                                                                                                                      |  |
| Description | The function <code>java-array-length</code> returns the length of <i>object</i> if this is a Java array. For multi-dimensional arrays, <code>java-array-length</code> returns the first dimension. If <i>object</i> is some other type of Java object, <code>java-array-length</code> returns <code>nil</code> . Otherwise it signals an error. |  |

|              | <i>Condition</i>                                                                                                                      |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | An abstract class, meaning that it is not signaled. Its readers can be used to access the subclasses.                                 |
| Package      | <code>lw-ji</code>                                                                                                                    |
| Superclasses | None.                                                                                                                                 |
| Subclasses   | <code>java-not-a-java-object-error</code><br><code>java-instance-without-jobject-error</code><br><code>java-not-an-array-error</code> |
| Readers      | <code>java-bad-jobject-caller</code><br><code>java-bad-jobject-object</code>                                                          |

Description      The condition class `java-bad-object` is an abstract class, meaning that it is never signaled. Its subclasses are signaled and its readers can be used to access those conditions.

*Conditions*

Summary      Conditions that are signaled when code defined by the Java interface fails to execute.

Package      `lw-ji`

Superclasses    `java-interface-error`

Subclasses    None.

Readers      `java-definition-error-class-name`  
`java-definition-error-name`

For `java-method-error` only:

`java-method-error-method-name`  
`java-method-error-args-num`

For `java-field-error` only:

`java-field-error-field-name`  
`java-field-error-static-p`

Description      The condition classes `java-class-error`, `java-method-error` and `java-field-error` are signaled when code that is defined by the Java interface (for example, `define-java-`

`caller, define-field-accessor)` fails to execute because the Java entity that it expects is not found.

They are subclasses of `java-definition-error`. `java-definition-error` is never signaled, and you should not signal these conditions.

The errors normally occur because the definition is wrong in some sense, but they can also happen if the Java virtual machine misses some of the classes or has a class definition that differs from what it should be.

`java-definition-error-name` returns the name of the Lisp function that fails, for example the `name` in the `define-javacaller` form.

`java-definition-error-class-name` returns the class name in the definition.

`java-method-error-method-name` returns the method name. If it is a constructor (`define-java-constructor`), `java-method-error-method-name` returns `nil`.

`java-method-error-args-num` returns the number of arguments that were passed to the call.

`java-field-error-field-name` returns the field name.

`java-field-error-static-p` queries whether the field was defined as static.

| Description  | <p>The class <code>java-exception</code> is the superclass of all conditions that are signaled for Java exceptions.</p> <p>The reader <code>java-exception-string</code> returns a string specifying the reason for the exception (result of <code>jobject-string</code> on the Java exception).</p> <p>The reader <code>java-exception-exception-name</code> returns a string with the exception name (name of the exception class, the result of <code>jobject-class-name</code> on the Java exception).</p> <p>The reader <code>java-exception-java-backtrace</code> returns a list of strings specifying the Java backtrace for the exception. Each string shows one Java frame.</p> |

| <b>java-field-setting-error</b> | <i>Condition</i>                                                                                                             |

| Description | <p>Conditions of class <code>java-field-setting-error</code> are signaled when setting a field is wrong, either because the field is final or because the value supplied is wrong. The setting can happen either by a call to <code>set-java-field</code> or by using <code>(setf name)</code> where <i>name</i> was defined by either <code>define-field-accessor</code> or <code>setup-field-accessor</code>.</p> <p>The new value returned by the accessor <code>java-field-setting-error-new-value</code> can be the keyword <code>:is-final</code>, which indicates that the error occurs because the field is final. Otherwise it is the new value, which is of an unacceptable type. The <i>class-name</i> of the field can be read using <code>java-field-setting-error-class-name-for-setting</code> (this is what <code>java-field-class-name-for-setting</code> would return for the same field).</p> |

| Description | <p>The condition class <code>java-method-exception</code> is signaled when an exception occurs inside a call to a Java method or a constructor. Such exceptions are normal behavior for Java, so these exceptions should in general be handled somehow.</p> <p>The <code>java-exception</code> accessors (<code>java-exception-exception-name</code>, <code>java-exception-string</code>) can be used on a <code>java-method-exception</code> and are useful for simple handling. For more complex handling, you can use <code>catching-java-exceptions</code> around pieces of your code, and then look at the actual Java exception.</p> <p>The reader <code>java-method-exception-name</code> returns the name of the Java caller (a Lisp symbol) that caused the exception.</p> <p>The reader <code>java-method-exception-class-name</code> returns the Java class name of the method or constructor.</p> <p>The reader <code>java-method-exception-method-name</code> returns the method name if the exception is inside a method, or <code>nil</code> if the exception is inside a constructor.</p> <p>The reader <code>java-method-exception-args</code> returns the arguments that were passed to the caller.</p> |

|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | Conditions signaled when an argument that needs to be an array of some type is not an array of the expected type.                                                                                                                                                                              |
| Package      | <code>lw-ji</code>                                                                                                                                                                                                                                                                             |
| Superclasses | <code>java-bad-jobject</code>                                                                                                                                                                                                                                                                  |
| Subclasses   | None.                                                                                                                                                                                                                                                                                          |
| Description  | The condition class <code>java-not-an-array-error</code> is signaled when an argument that needs to be an array is not an array, or when an argument that needs to be a primitive array is not a primitive array, or when an argument that needs to be an object array is not an object array. |
| Notes        | You can use the <code>java-bad-jobject</code> readers <code>java-bad-jobject-caller</code> and <code>java-bad-jobject-object</code> on these conditions.                                                                                                                                       |
| See also     | <code>java-bad-jobject</code><br><code>java-not-a-java-object-error</code><br><code>java-instance-without-jobject-error</code>                                                                                                                                                                 |

|               | <i>Constant</i>                                                       |
|---------------|-----------------------------------------------------------------------|
| Summary       | A constant representing a Java null pointer.                          |
| Package       | <code>lw-ji</code>                                                    |
| Initial Value | A null Java value.                                                    |
| Description   | The constant <code>*java-null*</code> represents a Java null pointer. |

## **java-object-array-element-type** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                        |  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Returns the element type of a Java array of a non-primitive element type.                                                                                                                                                                                                                                                                                                                              |  |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                                                                                                                                                                                                     |  |
| Signature   | <code>java-object-array-element-type object =&gt; result</code>                                                                                                                                                                                                                                                                                                                                        |  |
| Arguments   | <i>object</i> A Java object.                                                                                                                                                                                                                                                                                                                                                                           |  |
| Values      | <i>result</i> One of the keywords <code>:array</code> , <code>:object</code> and <code>:string</code> , or <code>nil</code> .                                                                                                                                                                                                                                                                          |  |
| Description | The function <code>java-object-array-element-type</code> returns the element type (as a keyword as listed in “Types and conversion between Lisp and Java” on page 198) if <i>object</i> is an array with non-primitive element type. If <i>object</i> is some other type of Java object, <code>java-object-array-element-type</code> returns <code>nil</code> . Otherwise it signals an error.         |  |
| Notes       | <ol style="list-style-type: none"><li>1. You can use <code>java-object-array-element-type</code> to test whether a Java object is an array of non-primitive element type.<br/>If you want to check whether <i>object</i> is any array (primitive or not), use <code>java-array-element-type</code> instead. Sometimes <code>java-primitive-array-element-type</code> may be more convenient.</li></ol> |  |
| See also    | <code>java-array-element-type</code><br><code>java-primitive-array-element-type</code><br>“Working with Java arrays” on page 210                                                                                                                                                                                                                                                                       |  |

## **java-objects-eq** *Function*

|         |                                                           |
|---------|-----------------------------------------------------------|
| Summary | Tests whether two objects represent the same Java object. |
|---------|-----------------------------------------------------------|

|             |                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>lw-ji</code>                                                                                                                                   |
| Signature   | <code>java-objects-eq obj1 obj2 =&gt; result</code>                                                                                                  |
| Arguments   | <code>obj1, obj2</code> Lisp objects.                                                                                                                |
| Values      | <code>result</code> A boolean.                                                                                                                       |
| Description | The function <code>java-objects-eq</code> tests whether <code>obj1</code> and <code>obj2</code> represent the same Java object.                      |

| Superclasses | <code>java-array-error</code>                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Subclasses   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description  | <p>The condition class <code>java-out-of-bounds-error</code> is signaled when a bad index value is passed to <code>jaref</code> or <code>jvref</code> or their setters, or bad <code>start/end</code> values are passed to <code>map-java-object-array</code> and other functions which access arrays.</p> <p>The condition class <code>java-storing-wrong-type-error</code> is signaled on an attempt to store value of wrong type into a</p> |

Java array by `(setf jvref)`, `(setf jaref)` or `map-java-object-array`.

You can use the `java-array-error` readers `java-array-error-caller` and `java-array-error-array` on these conditions.

## **java-primitive-array-element-type** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| Summary     | Returns the element type of a Java array of a primitive element type.                                                                                                                                                                                                                                                                                                                                                                         |                                                 |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                 |
| Signature   | <code>java-primitive-array-element-type object =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                            |                                                 |
| Arguments   | <code>object</code>                                                                                                                                                                                                                                                                                                                                                                                                                           | A Java object.                                  |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                           | A keyword, <code>t</code> or <code>nil</code> . |
| Description | The function <code>java-primitive-array-element-type</code> returns the element type (as a keyword as listed in “Types and conversion between Lisp and Java” on page 198) if <code>object</code> is an array with primitive element type. If <code>object</code> is some other type of Java object, <code>java-primitive-array-element-type</code> returns <code>nil</code> . Otherwise it signals an error.                                  |                                                 |
| Notes       | <ol style="list-style-type: none"><li>1. <code>java-primitive-array-element-type</code> is designed to be fast, so you can use it to test whether a Java object is an array of primitive element type.</li><li>2. If you want to check whether <code>object</code> is any array (primitive or not), use <code>java-array-element-type</code> instead. Sometimes <code>java-object-array-element-type</code> may be more convenient.</li></ol> |                                                 |

## **java-serious-exception** *Condition*

Summary      Conditions signaled when something in the system is not really not as it should be.

Package      `lw-ji`

Superclasses      `java-exception`

Subclasses      `java-id-exception`  
`java-low-level-exception`

Description      The condition class `java-serious-exception` is signaled for an exception that is serious, which means something in the system is not really not as it should be. Applications that get this should try to save everything and exit.  
In general, these exceptions should not happen, and you should not need to worry about these. If you do get any such exception, please report it with as many details as possible to Lisp Support, following the guidelines at [www.lisp-works.com/support/bug-report.html](http://www.lisp-works.com/support/bug-report.html).

## **java-type-to-lisp-array-type** *Functions* **lisp-array-type-to-java-type**

Summary      Return the Lisp array element type matching a supplied foreign type, or the foreign type matching a Lisp array element type.

Package      `lw-ji`

| Arguments   | <i>jtype</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A foreign type.                                  |
|             | <i>lisp-type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A Lisp type specifier.                           |
| Values      | <i>l-result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A Lisp array element type, or <code>nil</code> . |
| Description | <p>The function <code>java-type-to-lisp-array-type</code> returns the matching Lisp array element type for the foreign type <i>jtype</i>, which needs to be one of the foreign types corresponding to a Java primitive type, or <code>nil</code> if the argument is not such a foreign type.</p> <p>The function <code>lisp-array-type-to-java-type</code> returns the matching foreign type, corresponding to a Java primitive type, for the Lisp array element type <i>lisp-type</i>, or <code>nil</code> if there is no match.</p> |                                                  |

Both functions use the table below for doing the match:

Table 41.1 Correspondence between Java foreign types and Lisp array element types

| Foreign type          | Lisp type                       |
|-----------------------|---------------------------------|
| <code>jbyte</code>    | <code>(signed-byte 8)</code>    |
| <code>jshort</code>   | <code>(signed-byte 16)</code>   |
| <code>jint</code>     | <code>(signed-byte 32)</code>   |
| <code>jlong</code>    | <code>(signed-byte 64)</code>   |
| <code>jdouble</code>  | <code>double-float</code>       |
| <code>jfloat</code>   | <code>single-float</code>       |
| <code>jchar</code>    | <code>(unsigned-byte 16)</code> |
| <code>jboolean</code> | <code>(unsigned-byte 8)</code>  |

|             | <i>FLI type descriptor</i>                                                                                                                                                                                                                                   |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The Java virtual machine pointer type.                                                                                                                                                                                                                       |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                                                           |
| Syntax      | <code>java-vm-poi</code>                                                                                                                                                                                                                                     |
| Description | The FLI type <code>java-vm-poi</code> is used for the Java virtual machine pointer ( <code>Javavm*</code> in C). You need it only when you want to pass the virtual machine to <code>init-java-interface</code> by the <i>java-virtual-machine</i> argument. |
| See also    | <code>init-java-interface</code>                                                                                                                                                                                                                             |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | FLI types corresponding to the Java primitive types.                                                                                                                                      |
| Package     | <code>lw-ji</code>                                                                                                                                                                        |
| Description | These FLI types correspond to the Java primitive types. Normally you do not need to use any of these.<br><br>See “Types and conversion between Lisp and Java” on page 198 for discussion. |

## **jni-env-poi** *FLI type descriptor*

|             |                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The JNI environment pointer type.                                                                                                                                                                                                                                           |
| Package     | <code>lw-jl</code>                                                                                                                                                                                                                                                          |
| Syntax      | <code>jni-env-poi</code>                                                                                                                                                                                                                                                    |
| Description | <p>The FLI type <code>jni-env-poi</code> is used for the JNI environment pointer (<code>JNIEnv*</code> in C).</p> <p>When <code>jni-env-finder</code> is passed to <code>init-java-interface</code>, it needs to be a function that returns a <code>jni-env-poi</code>.</p> |
| See also    | <code>init-java-interface</code>                                                                                                                                                                                                                                            |

## **jobject** *FLI type descriptor*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The type of objects representing all non-primitive Java objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package     | <code>lw-jl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Syntax      | <code>jobject</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>The FLI type <code>jobject</code> is the type of objects representing all non-primitive Java objects (including arrays).</p> <p><code>jobjects</code> that represent the same Java object are not necessarily equal in any Lisp sense, and their addresses are not necessarily equal either. In fact, normally they will be different if they come from a different Java call. To check whether two <code>jobjects</code> represent the same Java object, use <code>java-objects-eq</code> (which takes CLOS Java instances too).</p> |
| Notes       | The <code>print-function</code> of <code>jobject</code> tries to print its Java class name, but what it prints may be a parent class of the actual                                                                                                                                                                                                                                                                                                                                                                                       |

class of the `jobject`. The function `jobject-class-name` returns the name of the actual class of the `jobject`, and also caches it in the `jobject`.

## **jobject-class-name** *Function*

Summary      Returns the name of the class to which a `jobject` belongs.

Package      `lw-ji`

Signature      `jobject-class-name jobject => class-name`

Arguments      `jobject`      A `jobject`.

Values      `class-name`      A string.

Description      The function `jobject-class-name` returns a string which is the name of the class to which the Java object `jobject` belongs. The name is then cached in the `jobject`.

The class for arrays is the internal class name, which is different from the way it is declared in Java. For other objects, the name is the full name of the class.

To obtain the class name as declared in Java, use `jobject-pretty-class-name`.

“Types and conversion between Lisp and Java” on page 198

## **jobject-ensure-global** *Function*

Summary Returns a global `jobject` pointing to the same Java object as the argument.

Package `lw-ji`

Signature `jobject-ensure-global jobject => global-jobject`

Arguments `jobject` A `jobject`.

Values `global-jobject` A `jobject`.

Description The function `jobject-ensure-global` returns a `jobject` pointing to the same Java object as the argument `jobject`, but which is guaranteed to be global.

In most cases, `jobjects` are global anyway. However, when using `map-java-object-array`, by default, the `jobjects` are local and cannot be used outside the scope of the function that was passed to `map-java-object-array`. Similarly, `jobjects` can be made local inside functions that are invoked by proxies, using the `:jobject-scope` option (see `define-lisp-proxy`). In these situations, if you want to access the Java object outside the scope of the function that was invoked by `map-java-object-array` or by the proxy, you need to use `jobject-ensure-global` inside the scope of the function, and then you can use the result outside the scope of the function.

If the argument `jobject` is not a `jobject` an error is signaled.

If the argument *jobject* is already a global reference, `jobject-ensure-global` simply returns it.

|          |                                                                                                                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <ol style="list-style-type: none"> <li>1. <code>jobject-ensure-global</code> cannot access local references outside the right scope (like any other function).</li> <li>2. <code>jobject-ensure-global</code> does not accept an instance of <code>standard-java-object</code>.</li> </ol> |

| Summary     | The predicate for whether a Java object is an instance of a given Java class.                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                              |
| Package     | <code>lw-ji</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                              |
| Signature   | <code>jobject-of-class-p object class-spec =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                              |
| Arguments   | <code>object</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A Java object.                                                               |
|             | <code>class-spec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A class specifier that <code>find-java-class</code> accepts or a Java class. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A generalized boolean.                                                       |
| Description | <p>The function <code>jobject-of-class-p</code> takes a Java object and a Java class specification, and returns true if the object is an instance of this class or any of its subclasses.</p> <p><i>class-spec</i> must be either a class specifier that <code>find-java-class</code> accepts, or a Java class, that is a <code>Jobject</code> of class <code>java.lang.Class</code>. The Java class may be an interface, in which case the result verifies whether the object implements the interface.</p> |                                                                              |

## **jobject-p** *Function*

Summary      The predicate for objects of type `jobject`.  
Package      `lw-ji`  
Signature      `jobject-p object => result`  
Arguments      `object`      A Lisp object.  
Values      `result`      A boolean.  
Description      The function `jobject-p` is the predicate for objects of type `jobject`.  
See also      `jobject`

`get-jobject`  
`ensure-is-jobject`  
“Types and conversion between Lisp and Java” on page 198

## **jobject-pretty-class-name** *Function*

Summary      Returns a string which is the name of the class to which a given `jobject` belongs.  
Package      `lw-ji`  
Signature      `jobject-pretty-class-name jobject => name`  
Arguments      `jobject`      A `jobject`.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                     |           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| Values      | <i>name</i>                                                                                                                                                                                                                                                                                                                                                                                                         | A string. |
| Description | The function <code>jobject-pretty-class-name</code> returns a string which is the name of the class to which the <code>jobject</code> object belongs. The name is then cached in the <code>jobject</code> .<br><br>The class for arrays is "prettified", which means converting it to the way it is declared in Java. For other objects, <i>name</i> is the same as the result of <code>jobject-class-name</code> . |           |
| See also    | <code>jobject</code><br><code>jobject-class-name</code><br>“Types and conversion between Lisp and Java” on page 198                                                                                                                                                                                                                                                                                                 |           |

| <b>jobject-string</b> |                                                                                                                                                                                      | <i>Function</i>          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| Summary               | Calls the Java method <code>object.toString</code> on a Java object.                                                                                                                 |                          |
| Package               | <code>lw-jl</code>                                                                                                                                                                   |                          |
| Signature             | <code>jobject-string jobject =&gt; string</code>                                                                                                                                     |                          |
| Arguments             | <i>jobject</i>                                                                                                                                                                       | A <code>jobject</code> . |
| Values                | <i>string</i>                                                                                                                                                                        | A string.                |
| Description           | The function <code>jobject-string</code> returns a string which is the result of calling the Java method <code>object.toString</code> on the Java object <code>jobject</code> on it. |                          |

| Values      | <code>lisp-object</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A Lisp object.                               |
| Description | <p>The function <code>jobject-to-lisp</code> converts a <code>jobject</code> to a Lisp object where possible.</p> <p>The argument <code>object</code> must be a <code>jobject</code> or <code>nil</code>, otherwise an error is signaled. If <code>object</code> is <code>nil</code>, <code>jobject-to-lisp</code> returns <code>nil</code>. If <code>object</code> is a <code>jobject</code> of type <code>java.lang.String</code> or any of the primitive types, <code>jobject-to-lisp</code> returns the matching Lisp object. See “Types and conversion between Lisp and Java” on page 198 for a full description.</p> <p>If the conversion cannot be done, the return value depends on the value of <code>nil-when-fail</code>. When <code>nil-when-fail</code> is true <code>jobject-to-lisp</code> returns <code>nil</code> for failure. When <code>nil-when-fail</code> is false, <code>jobject-to-lisp</code> returns the <code>jobject</code> itself. The default value of <code>nil-when-fail</code> is true.</p> |                                              |
| Notes       | <p>You need to pass <code>nil-when-fail</code> as <code>nil</code> for the cases when you want to be able to distinguish between return value <code>nil</code> for the Java boolean <code>false</code> and failure to convert. When you do that, the caller code needs to compare the result to the argument, instead of checking for non-<code>nil</code>, like this:</p> <pre>(let ((my-res (jobject-to-lisp my-obj nil)))   (if (eq my-obj my-res)       (fail-branch)       (success-branch)))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                              |

| <code>array</code>     | A Java array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |               |                    |                         |                        |                                        |
| <code>index</code>     | A non-negative integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |               |                    |                         |                        |                                        |
| <code>new-value</code> | A valid value for <code>array</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                    |               |                    |                         |                        |                                        |
| Values                 | <code>element</code> A Lisp object, a <code>jobject</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                    |               |                    |                         |                        |                                        |
| Description            | <p>The function <code>jvref</code> reads and sets the value of an element in the Java array <code>array</code>.<br/> <code>index</code> must be in the right range:</p> $0 \leq \text{index} < (\text{java-array-length } \text{array})$ <p><code>new-value</code> must be a valid value to store in <code>array</code> (discussed below)</p> <p><code>jvref</code> returns the corresponding element from <code>array</code>. If the element is of a primitive type, or is of type <code>java.lang.String</code>, it is converted to the Lisp object, otherwise it is returned as a <code>jobject</code> or <code>nil</code> if it is <code>null</code>. See “Types and conversion between Lisp and Java” on page 198.</p> <p><code>(setf jvref)</code> sets the element to <code>new-value</code>. <code>new-value</code> must be a valid element for <code>array</code>. For a primitive array, <code>new-value</code> must be a Lisp object of the correct type:</p> <ul style="list-style-type: none"> <li><code>byte, short, int, long</code><br/>Integers with less than 8, 16, 32 and 64 bits respectively.</li> <li><code>float, double</code></li> </ul> |                    |               |                    |                         |                        |                                        |

Any float.

boolean

nil or t.

char

Integers in the inclusive range [0, #xffff].

For a non-primitive array, *new-value* must be convertible to a  *jobject* of the correct class. If the element type of *array* is `java.lang.Object` (`java-array-element-type` returns `:object`), then any Lisp value that can be converted to a Java primitive type is acceptable (see “Types and conversion between Lisp and Java” on page 198), as well as strings and any Java object. If the element type of *array* is `java.lang.String` (`java-array-element-type` returns `:string`), then strings or Java objects of class `java.lang.String` are acceptable. In all other cases, only Java objects are acceptable, and need to be of the correct type.

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | <p>For accessing multiple elements in the same array, the multiple access functions (<code>map-java-object-array</code>, <code>primitive-array-to-lisp-array</code>, <code>lisp-array-to-primitive-array</code>) can be much faster.</p> <p><code>jvref</code> and <code>(setf jvref)</code> access the top level of the array. If <i>array</i> is multi-dimensional, <code>jvref</code> and <code>(setf jvref)</code> will return and set the sub-array. See <code>jaref</code> for accessing elements in a multi-dimensional array.</p> <p><code>jvref</code> and <code>(setf jvref)</code> are slightly faster than <code>jaref</code> and <code>(setf jaref)</code> with one index, and give a proper error when called with the wrong number of arguments.</p> |

|           |                                                                            | <i>Function</i>                              |
|-----------|----------------------------------------------------------------------------|----------------------------------------------|
| Summary   | Converts a Lisp object to an appropriate <code>jobject</code> .            |                                              |
| Package   | <code>lw-ji</code>                                                         |                                              |
| Signature | <code>lisp-to-jobject lisp-object &amp;optional errorp =&gt; result</code> |                                              |
| Arguments | <code>lisp-object</code>                                                   | A Lisp object.                               |
| Values    | <code>result</code>                                                        | A <code>jobject</code> or <code>nil</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>lisp-to-jobject</code> tries to convert the argument <i>lisp-object</i> to a <code>jobject</code> . It succeeds if <i>lisp-object</i> is of a type that matches any Java primitive type or is a string. In general that means integers up to 64 bits, floats, <code>t</code> , <code>nil</code> and strings.<br><br>See “Types and conversion between Lisp and Java” on page 198 for a full description. |
|             | If it fails, <code>lisp-to-jobject</code> calls <code>cl:error</code> , unless the argument <code>errorp</code> is <code>nil</code> , in which case it returns <code>nil</code> .                                                                                                                                                                                                                                           |

| Description | The function <code>make-java-array</code> creates a Java array object <i>array</i> .<br><br><i>type</i> specifies the type of elements in <i>array</i> . To make an array of any Java class, <i>type</i> needs to be a string with the full name of the class. To make an array of primitive type, <i>type</i> should |                                                                                                                                                                                                                                                                                                                 |

be the corresponding keyword (`:byte`, `:short`, `:int`, `:long`, `:float`, `:double`, `:char` or `:boolean`). `type` can also be `:object` or `t` meaning `java.lang.Object`, and `:string` meaning `java.lang.String`, and the FLI types matching the primitive types.

The dimension(s) of the array are specified by `first-dim` and the `dims` list, which must all be non-negative integer(s).

`make-java-array` returns the new array.

## make-java-instance *Function*

Summary      Create a CLOS instance and its `jobject`.

Package      `lw-ji`

Signature      `make-java-instance symbol-or-class &rest args => instance`

Arguments      `symbol-or-class`    A class designator.  
                   `args`                Lisp objects.

Values          `instance`          A CLOS object.

Description      The function `make-java-instance` creates a CLOS instance and its `jobject`.

The class `symbol-or-class` must be a subclass of `standard-java-object`, and must have been associated with a Java constructor by passing the class name to `define-java-constructor` or `setup-java-constructor` as the `class-symbol` argument (the importing interface, when defining a class, does it automatically).

`make-java-instance` makes the CLOS instance by calling `make-instance` on `symbol-or-class`, then passing the instance and `args` to `create-instance-jobject-list` to create the `jobject`, and then returns the instance.

The result is a CLOS instance of *symbol-or-class*, which can be passed to Java interface functions and Java methods.

## **make-lisp-proxy**

### **make-lisp-proxy-with-overrides**

### *Functions*

Summary      Make a Lisp proxy.

Package      `lw-ji`

Signature      `make-lisp-proxy name &key user-data print-name overrides overrides-plist => proxy`

Signature      `make-lisp-proxy-with-overrides name &rest args &key user-data print-name &allow-other-keys => proxy`

Arguments      `name`      A symbol.

`user-data`      A Lisp object.

`print-name`      A string or a symbol.

`overrides`      An association list.

`overrides-plist`      A plist.

`args`      A plist.

Values      `proxy`      A `jobject`.

Description      The functions `make-lisp-proxy` and `make-lisp-proxy-with-overrides` make a Lisp proxy, which is a Java proxy where method invocation ends up calling Lisp code. The result is a `jobject proxy` which represents the proxy, which

can then be used in Java where an object that implements any of the interfaces that the proxy implements is required.

**Note:** The `jobject` is "local", which means that if it is generated in the scope of a call from Java it must be used (passed to Java method, return to the call from Java or pass it to `jobject-ensure-global`) in the scope of the call from Java. You cannot store it in Lisp and use it later (but you can do that with the result of `jobject-ensure-global`). If the `jobject` is generated not in the scope of a Java call, it must be used on the same thread that it was made.

`name` must be associated with a proxy definition, either by `define-lisp-proxy` or `setup-lisp-proxy`. The proxy definition determines which interfaces the proxy implements, and what happens when a method is invoked on the proxy. The processing of invocation of a method on the proxy is described in the entry for `define-lisp-proxy`.

`user-data` is an arbitrary object. It is passed to the Lisp function if the proxy definition specifies that it should be passed (keyword `:with-user-data` or `:default-function-with-user-data` for the default function).

`print-name` specifies the name of the proxy, after it is converted to a string by `c1:princ-to-string`. If the proxy definition has a `print-name` too, the full print name of the proxy is formed by concatenating the definition's `print-name` and the proxy's `print-name` separated by " - ", otherwise the full print name is the proxy's `print-name`. The full print name is used when printing the proxy, and is also returned when the Java method `toString` is applied to it. If `print-name` is `nil`, a counter is used.

`overrides`, if supplied, must be an association list specifying overriding (see "Overrides" below), that is a list of conses where the `c1:car` is the symbol to override and the `c1:cdr` is the target. When `overrides` is non-nil `overrides-plist` is ignored.

If *overrides-plist* is supplied it must be a plist specifying overriding, that is a list of even length where each even element is a symbol to override and the following odd element is the target.

The *args* argument of `make-lisp-proxy-with-overrides` is used as a plist specifying overrides, after removing any occurrences of `:print-name` and `:user-data` from it.

## Overrides

Overrides allow `make-lisp-proxy` and `make-lisp-proxy-with-overrides` to override symbols in the proxy definition, which means that instead of calling the symbol in the proxy definition the target in the overrides is called. See the entry for `define-lisp-proxy` for details of the processing.

`make-lisp-proxy-with-overrides` is intended to make it simpler to use overrides. It is equivalent to calling `make-lisp-proxy` with *overrides-plist*, and actually calls `make-lisp-proxy` (so may get errors that look like they came from `make-lisp-proxy`).

`make-lisp-proxy` and `make-lisp-proxy-with-overrides` signal error if name is not associated with a proxy definition, and if any overrides are not of the right form or any of the functions to call is not a function designator. They may also signal an error if the proxy definition was not initialized and they failed to initialize it.

## map-java-object-array

*Function*

### Summary

Apply a function to the elements in an array.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Values      | <code>result</code> A list or a Lisp vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | <p>The function <code>map-java-object-array</code> applies the function <i>function</i> to the elements in the Java array <i>array</i>. The default behavior is simply to apply <i>function</i> to each element. The keyword arguments can be used to change this behavior, including modifying elements.</p> <p><i>function</i> should take one or two arguments, depending on <i>pass-args</i>. The default value of <i>pass-args</i> is <code>:element</code>, which means that <i>function</i> takes one argument, the element in the array. <i>pass-args</i> can also be <code>:element-index</code>, and then <i>function</i> should take two arguments, the element and the index. <i>pass-args</i> can also be <code>:index</code> in which case <i>function</i> just takes the index. The latter case is useful when <code>map-java-object-array</code> is used to modify the element in the array. When <i>function</i> is <code>nil</code>, the "result" of the function call is the element itself. That is useful for simple collection (that is, supplying a true value of <i>collect</i>).</p> |

**Note:** When the element that is passed to *function* is a `jobject`, it is by default a "local" object, which means it must not be used outside the dynamic scope of the function call. `collect` and `convert` can change this.

When *write-back* is `nil` the result of the call to *function* is ignored. When *write-back* is non-`nil`, the result of *function* is the new value to write back. The default value of *write-back* is `nil`.

When *reverse* is non-`nil` `map-java-object-array` starts from the highest index and maps down, otherwise it maps up. The default value of *reverse* is `nil`.

*start* and *end* specify the range in *array* to map: *start* defaults to 0 and is inclusive, and *end* defaults to the length of *array* and is exclusive. If either of these is not an integer or is out of bounds, or *end* is smaller than *start*, then an error of type `java-out-of-bounds-error` is signaled.

*pass-args* controls the arguments to *function* as described above.

*collect*, if non-`nil`, specifies that the results of applying *function* should be collected and returned from `map-java-object-array`. If *collect* is `t`, `map-java-object-array` returns a list of the results. *collect* can also be `:vector` or `cl:vector`, in which case *result* is a Lisp vector. When *convert* is either `nil` or `t`, *collect* overrides it and forces conversion of primitive types and strings to Lisp objects, and makes *jobjects* non-local, so they can be used outside the scope of the function calls and `map-java-object-array`. The default value of *collect* is `nil`.

*convert* controls conversion to Lisp objects. When *convert* is `t`, primitive types and strings are converted to Lisp objects before they are passed to *function*. When *convert* is `nil`, all elements are passed as *jobjects*. Note that when *collect* is non-`nil` and *convert* is `nil` or `t`, *collect* overrides *convert* as described above. The default value of *convert* is `t`.

When *convert* is one of :force-nil, :force-local or :force-global it overrides *collect*. :force-nil causes the object to pass as a *jobject* (the same as when *collect* is nil and *convert* is nil). :force-local causes primitive types to pass as Lisp objects, and other types as local *jobjects* (the same as when *collect* is nil and *convert* is t). :force-global causes primitive types to be passed as Lisp objects and other types as global objects.

**Note:** local *jobjects*, which you get when *convert* is either :force-nil or :force-local, or when *collect* is nil and *convert* is not :force-global, must not be used outside the scope of the function *function* that is passed to `map-java-object-array`. Using local objects out of scope can cause the system to crash (rather than signal an error). Note that you must not even use a local *jobject* from one call to *function* in another call to *function* within the same call to `map-java-object-array`.

Converting to global objects adds a substantial overhead to the system, though for small arrays this is not very bad. If you want to map over a large array, and dynamically decide to use only some of the *jobjects* out of scope, you can convert local *jobjects* to global using `jobject-ensure-global`.

When *write-back* is true, the result of the application of *function* is written back to *array*. The default value of *write-back* is nil.

If *array* is not a non-primitive Java array, or *pass-args* or *collect* is not one of the acceptable values, or *write-back* is non-nil and *function* returns an object of wrong type, `map-java-object-array` signals an error of type `java-array-error`.

- Notes
1. `map-java-object-array` accesses only non-primitive arrays. For primitive arrays use one of `primitive-array-to-lisp-array`, `lisp-array-to-primitive-array`, `get-primitive-array-region` and `set-primitive-array-region`.
  2. The function `java-object-array-element-type` can be used to test whether a Java object is a non-primitive array.
  3. When accessing more than one element, `map-java-object-array` may be much faster than accessing the elements using `jvref` or `jaref`.
  4. `map-java-object-array` traverses one level. If a multi-dimensional array is supplied, the elements that it passes to *function* are sub-arrays (which may be `null` too).

## primitive-array-to-lisp-array lisp-array-to-primitive-array

### Functions

- Summary      Copy elements between a Java primitive array and a Lisp array of matching type.
- Package      `lw-ji`
- Signature     `primitive-array-to-lisp-array p-array &key start end target-start target-end lisp-array => l-result`

|             | <i>p-result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <i>primitive-array</i> or a new primitive array.          |
| Description | <p>The function <code>primitive-array-to-lisp-array</code> takes a Java array <i>p-array</i> of primitive type and copies elements from it to a Lisp array of matching type. The target <i>lisp-array</i> is created by default, but can also be supplied as an argument.</p> <p>The function <code>lisp-array-to-primitive-array</code> takes a Lisp array <i>l-array</i> of an acceptable Lisp type and copies elements from it to a Java array of matching type. The target <i>primitive-array</i> is created by default, but can also be supplied as an argument.</p> <p><i>start</i> and <i>end</i> are bounding index designators for the source <i>p-array</i> or <i>l-array</i>, specifying the range to copy.</p> <p><i>target-start</i> and <i>target-end</i> are used only if the target is supplied (by <i>lisp-array</i> or <i>primitive-array</i>). They specify the start and end for copying in the target. The actual number of elements copied is the minimum of the lengths specified for the source and for the target.</p> <p>If the target (<i>lisp-array</i> or <i>primitive-array</i>) is not supplied, these functions create an array of the correct type and the copy length, and copy into it.</p> |                                                           |

The Lisp array that is passed to `lisp-array-to-primitive-array` must be of one of the types listed below, and when the target array is supplied, its type must match the type of the source array according to the table below, except that `cl:base-char` array (`cl:simple-base-string`) is acceptable when the Java side is `byte`.

Table 41.2 Correspondence between Java primitive and Lisp array element types

Table 41.3

| Java primitive type  | Keyword<br>(result of <code>java-array-element-type</code> ) | Lisp type<br>(result of <code>cl:array-element-type</code> ) |
|----------------------|--------------------------------------------------------------|--------------------------------------------------------------|
| <code>byte</code>    | <code>:byte</code>                                           | <code>(signed-byte 8)</code>                                 |
| <code>short</code>   | <code>:short</code>                                          | <code>(signed-byte 16)</code>                                |
| <code>int</code>     | <code>:int</code>                                            | <code>(signed-byte 32)</code>                                |

For `boolean`, 1 is `true` and 0 is `false`.

Notes For a large number of elements, these functions are much faster than `jvref`. If the primitive data is needed for passing to or from foreign functions, use `get-primitive-array-region` and `set-primitive-array-region` instead. These functions work only on arrays with one dimension with

primitive element type. For non-primitive arrays of one dimension you can use `map-java-object-array`.

**read-java-field****checked-read-java-field****set-java-field****check-java-field****java-field-class-name-for-setting***Functions*

Summary Access a field, either static or in a Java object.

Package `lw-jl`

Signature `read-java-field full-field-name &optional object => field-value`

Signature `checked-read-java-field full-field-name &optional object => field-value-or-nil, nil-or-condition`

Signature `set-java-field full-field-name value &optional object => value`

Signature `check-java-field full-field-name static-p => result`

Signature `java-field-class-name-for-setting full-field-name static-p => class-name or nil`

Arguments `full-field-name` A string.

`object` A Java object or `nil`.

`value` A type.

| Description | <p>The functions <code>read-java-field</code>, <code>checked-read-java-field</code> and <code>set-java-field</code> access the value of a field in a Java Object or a static field.</p> <p>The functions <code>check-java-field</code> and <code>java-field-class-name-for-setting</code> are used to check whether it is possible to access the value of the field.</p> <p><i>full-field-name</i> needs to be a full field name including the package and class, for example "<code>java.io.File.separator</code>".</p> <p>If <i>object</i> is supplied and is non-<code>nil</code>, it must be a Java object from which to read/to which set the value. The field must be non-static in this case. If <i>object</i> is <code>nil</code>, the field must be static.</p> <p><code>read-java-field</code> returns the value of the field. If it fails to get it, it signals an error. If the class is not found, this is a <code>java-class-error</code>, if the field is not found it is a <code>java-field-error</code>.</p> <p><code>checked-read-java-field</code> returns the value like <code>read-java-field</code> and another value which is <code>nil</code> when the read is successful. If the class or the field is not found, <code>checked-read-java-field</code> returns <code>nil</code> and a condition specifying the error (<code>java-field-error</code> or <code>java-class-error</code>). Note that it may still signal other errors, for example if <i>full-field-name</i> does not look like a proper field name.</p> <p><code>set-java-field</code> sets the field to the <i>value</i>. <i>value</i> must be of an acceptable type (see “Types and conversion between Lisp</p> |                                                                                                                          |

and Java” on page 198) and the field must not be final, otherwise it signals `java-field-setting-error`.

`check-java-field` checks whether the field exists and matches the value of `static-p`, and returns a boolean *result* accordingly.

`java-field-class-name-for-setting` checks whether the field exists and matches the value of `static-p` and whether it is not final, and if it is returns the class name of the field. It returns `nil` otherwise. `java-field-class-name-for-setting` is useful for checking whether `set-java-field` can be used on a field, and whether a value is suitable to be stored in his field, by using `jobject-of-class-p`.

Notes It is also possible to access fields using accessors defined by `define-field-accessor` and `setup-field-accessor`.

## record-java-class-lisp-symbol *Function*

Summary Records a correspondence between the name of a Java class and a Lisp symbol.

Package `lw-ji`

Signature `record-java-class-lisp-symbol java-class-name lisp-name => lisp-name`

Arguments `java-class-name` A string.  
`lisp-name` A symbol.

|             |                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | <i>java-class-name</i> must be the precise full name of a Java class.<br><i>lisp-name</i> must be a Lisp symbol corresponding to the Java class. The function <code>record-java-class-lisp-symbol</code> records this correspondence. | At the time of writing this correspondence is used only to find CLOS class names from Java class name by <code>create-instance-from-jobject</code> and <code>ensure-lisp-classes-from-tree</code> .<br><br><code>record-java-class-lisp-symbol</code> is used by the importing interface when <i>lisp-name</i> is non-nil. You can use it yourself, but <i>lisp-name</i> must name an appropriate class (subclass of <code>standard-java-object</code> ). |

|-------------|---------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary     | Resets the Java interface.                                                                                                      |                 |
| Package     | <code>lw-ji</code>                                                                                                              |                 |
| Signature   | <code>reset-java-interface-for-new-jvm &amp;key for-shaking-p</code>                                                            |                 |
| Arguments   | <code>for-shaking-p</code> A generalized boolean.                                                                               |                 |
| Values      | None.                                                                                                                           |                 |
| Description | The function <code>reset-java-interface-for-new-jvm</code> resets the Java interface, which means eliminating all cached infor- |                 |

mation. *for-shaking-p* needs to be true when it is called before shaking.

The system automatically calls `reset-java-interface-for-new-jvm` when delivering, so you do not need to call it then. Applications should never use it. It may be useful during debugging if the JVM is manipulated in some way.

The default value of *for-shaking-p* is `nil`.

| Signature   |                                  | <code>send-message-to-java-host message-string where-keyword =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments   | <i>message-string</i>            | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | <i>where-keyword</i>             | One of the keywords <code>:append</code> , <code>:add</code> ,<br><code>:prepend</code> , <code>:add-no-scroll</code> , <code>:append-no-</code><br><code>scroll</code> and <code>:reset</code> .                                                                                                                                                                                                                                                                 |
| Values      | <i>result</i>                    | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |                                  | The function <code>send-message-to-java-host</code> sends a message to the Java host. It funcalls the function that was passed as the <code>send-message-to-java-host</code> argument to <code>init-java-interface</code> , or the default function, with <i>message-string</i> and <i>where-keyword</i> .<br><br>On Android <code>init-java-interface</code> is given a function that ends up calling the method <code>com.lispworks.Manager.addMessage</code> . |

The default function checks the keyword and then writes the string to `cl:*terminal-io*`, which is probably good enough for testing purposes.

`result` is `t` if there is a function, and `nil` otherwise.

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| Notes              | The intended meanings of <code>where-keyword</code> are:                                                              |
|                    | <code>:reset</code> Erase any existing text and replace it by the message.                                            |
|                    | <code>:prepend</code> Insert the message and a newline before any existing text.                                      |
|                    | <code>:add-no-scroll</code> Add the message after all existing text.                                                  |
|                    | <code>:add</code> Like <code>:add-no-scroll</code> , and scroll to the beginning of the new message.                  |
|                    | <code>:append-no-scroll</code> Like <code>:add-no-scroll</code> , plus add a following newline.                       |
|                    | <code>:append</code> Like <code>:append-no-scroll</code> , and scroll to the beginning of the new message.            |
| Compatibility note | The values <code>:add-no-scroll</code> and <code>:add</code> for <code>where-keyword</code> are new in LispWorks 7.1. |
